The objective is the most important item of photographic apparatus, because upon it depends the perfection with which a correct and well-defined picture is projected upon the plane surface of the sensitive plate of objects in the different planes forming the field of view, which naturally would come to a focus on a series of flattened surfaces. This flattened surface must be equally illuminated and sharply defined, within a limit of confusion from $\frac{1}{12}$ to $\frac{1}{36}$ of an inch, over a sufficiently wide angle. A good objective must also pass sufficient light to produce the required effect, at a distance from the photographic plate; the chemical and visual foci must coincide exactly, and it must not distort straight or parallel lines. The fulfilment of these conditions is complicated by the presence of sundry focal displacements or aberrations of light, which exist in combination with the different sides of the central and marginal pencils of rays passing through the lens. It is corrected by varying the curves of the component lenses and by the use of a diaphragm. (2) Coma, or blur, due to lateral spherical aberration, is caused by difficulty in focusing, or focusing at different angles, and by combining converging with diverging single and double convex surfaces, or in two separate curved surfaces, one set focusing tangentially as more or less horizontal lines, the other radially as more or less vertical lines. It increases with the obliquity of the rays and causes want of definition and focus at the corners of the objective. (4) Curvature of field, also increasing with the obliquity of the rays. (5) Distortion, outward or inward, according to the nature and construction of the objective. With the single meniscus view lens, used with its convex sides towards the object, the object will appear rounded from one side of the square will appear barrel shaped from inward contraction of the lines towards the centre; but with the convex surface towards the object and the diaphragm behind, it will appear with concave sides, due to the deviation from the true spherical form. (6) Chromatic aberration. The dispersion of the white light passing through the lens, and the different coloured rays composing it, coming to a focus at different distances from the visual focus in the order of their wave-lengths. It is corrected by the combination of the objective surfaces of different colours. For ordinary photographic work it suffices for the blue-violet and yellow rays to be coincident, but for the new processes of photography in three colours, apochromatic lenses, in which perfect coincidence of the coloured rays is secured, are required to obtain the accurate register of the three images. The corrections are effected by compensating lenses of different refractive powers (see Aberration).

In constructing photographic objectives these aberrations and distortions have to be neutralized, by regulating the curves of the different positive and negative component lenses, the refractive and dispersive indices of the glasses from which they are made, and the distances of the refracting surfaces, so as to make the objective free from spherical aberration, or possible stigmatic or focusing to a point, giving an image well defined and undistorted. This perfect correction could never be effected in objectives made before 1887, and very few could be effectively used at their full apertures, due to the spherical aberration, or possible stigmatic or focusing to a point, giving an image well defined and undistorted. The introduction of rapid gelatin dry plates enabled photographs to be taken with much greater rapidity than before, and led to a demand for greater intensity of illumination and better definition in lenses to meet the new conditions. (7) Aberrations which are inherent, and not due to the objective surface, arise from the impossibility of obtaining a perfect focus at different points on the plate, and may be divided into field and point aberrations.

They are also sometimes classified according to their rapidity, as they are known for their effective apertures, into “extra rapid,” with apertures larger than f/6; “rapid,” with apertures from f/6 to f/8; “slow,” with apertures less than f/11. Another classification is according to the angle of view: “narrow-angle” up to 35°; “medium angle” up to 60°; “wide angle” up to 90, 100°, or more. Many lenses are made in series, differing in rapidity and angle of view as well as in length of focus.

Photographic objectives may be classified as follows:

1. Single achromatic combinations.
2. Unsymmetrical doublets.
3. Symmetrical doublets.
4. Triple combinations.
5. Astigmatic combinations—symmetrical and unsymmetrical.
6. Telephotographic objectives.
7. Anachromat combinations.

They include the following, which are useful in photography:

1. Old types.
2. New types.

The following are some of the best-known objectives of this type:

- J. Grubb’s “Aplanatic” (1857), f/15 to f/30
- H. Dallmeyer’s “Wide Angle Landscape Lens” (1865), f/15, angle 75°
- W. R. Wray’s “Landscape Lens” (1886), f/11, angle 63°, which is also useful in portrait work.
- J. F. Voigtlander’s “Wide-Angle Landscape Lens” (1888)

In the diagrams of lenses which follow, a uniform system of indicating the nature of the glass employed by means of the shading has been adopted.

- Flint glass is indicated thus:—
- Crown glass of low refractive power thus:—
- Crown glass of high refractive power thus:—

These two are used indiscriminately in lenses made before the introduction of the new Jena glass.

Extra light flint glass thus:—
In most cases the front of the lens is on the right.
It had six reflecting surfaces and nearly approached a triplet (fig. 21). Steinheil’s “Group Aplanats” (1879), f/6.4, angle 70°, were superseded in 1881 by the “Group Antiplanets,” f/5, angle 70°, lenses of the same object type (fig. 22). They were a further advance on the “Aplanats,” working at larger apertures and giving better definition. This lens is interesting as the first angitastigmatic lens, was subsequently improved by combining a “crowns-shaped” high refraction, with a “flint-shaped” lower refraction, though made of old glasses. In his “Rapid Antiplanet” (1893), f/6.5, angle 30°, Dr. R. Steinheil improved the “Group Antiplanets” as regards astigmatism and rendering it better, partly by a triple long-focus negative element consisting of a crown between two flints, with a heavy baryte crown in the front element instead of a flint (fig. 23). Voigtlander’s “Planar” (1875) was the first practical Petzval lens in 1876. It was improved in 1878 and 1885, and now makes two lenses on the same principle, series I, f/5.2, angle 28°, for ordinary portrait and projection, and series II, f/3.2, angle 22° (1900) for astrography, cinematography, &c., when maximum definition is required over a small field. Both are quite free from coma.

2. Unsymmetrical Doubles: Old Types.—This class includes objectives with comparatively large apertures formed of two dissimilar combinations, in most cases correcting each other, or having a diaphragm between them. In some the single elements may be used independently. All the older “portrait” lenses, some of the planar doubles and Fr. von Voigtlander’s “Orthoscopic Lens” (1857), now disused, are of this type. Even with the present improved conditions, the portraitist working in a studio requires a quick-acting objective of large effective aperture and comparatively short focus, giving a brilliant well-defined image of near objects in different planes over a restricted field of view. The early single lenses were found to be too slow for portraiture by the daguerreotype and talbotype processes, and the efforts of opticians were directed to the problem of obtaining the maximum amount of light, together with good definition and flatness of field, and about 1840 compound lenses were brought out by Andrew Ross and C. Chevalier, consisting of two achromatic compounds, one at each end of a tube. Ross’s lens, made for H. Collen, is interesting as the first lens corrected photographically to the index of the chemical foci were coincident (fig. 18). Ch. Chevalier also combined lenses of different foci, as is now done for “convertible” objectives, used singly or combined. He also fitted them with an iris diaphragm. These forms were soon superseded by the compound portrait lens, calculated by J. Petzval and brought out by Fig. 18.—First English Portrait Lens.

Fr. von Voigtlander in 1841. It consists of two dissimilar achromatic combinations widely separated. At first the diaphragms were in front, but now they are central. The front element is a plano-convex composed of a biconvex crown separated by an air-space from a concavo-convex flint (fig. 19). This form of objective quickly supplanted all other for portraitists, and is still largely used, though it has defects which lenses of this use for general purposes and is being superseded for portraiture by some of the rapid angitastigmats. In his “Quick Acting Portrait Lens” (1860), f/4, angle 45°, J. H. Dallmeyer improved the correction for spherical aberration, and in his “Extra Quick Acting Portrait Lens” (1860), f/2.2, used for cinematographic work, attained greater rapidity.

In the “Patent Portrait Lens” (1866), f/3, f/4 and f/6, angles 30° to 50° (fig. 20), he made great changes in the form and relative positions of the back elements, giving a flatter field and freedom from flare spot. By separating the two components of the back element more or less spherical aberration could be introduced to give softness of definition and greater depth of focus. In 1875 Dr. A. Steinheil made an unsymmetrical aplanatic portrait combination of peculiar construction working at f/2.4, an improvement on his similar symmetrical “Portrait-Aplanat,” Fig. 19.—Portrait Lens.

Form I. of 1874, but was superseded in 1881 by the “Portrait Aplanat,” f/2.5 and free from astigmatism over an angle of 14°.

Fig. 23.—R. Steinheil’s Improved Group Aplanats.

Moore’s above these objective lens of large aperture, but unsymmetrical doubles have also been made for landscape work. J. T. Goddard’s “Combination Landscape Lens” (1859) was one of the first, and was free from distortion, gave a flat field, and could be aplanated as a converging back lens in 1864. T. Ross introduced his “Actinic Doubles,” modified from the Collen lens, in three series —“small angle,” f/8, angle 40° to 50°; ordinary angle, f/14, angle 40° to 50°; “large aperture,” f/16, angle 80° to 90°. These lenses were similar to the “Globe,” but unsymmetrical and more rapid. The separate elements could be used alone. Some of them were fitted with a shutter near the diaphragm. They were superseded by some unsymmetrical doubles.

FIG. 24.—Ordinary Angle Portrait Lens.

Most of the above portrait objectives of large aperture, but unsymmetrical doubles have also been made for landscape work. J. T. Goddard’s “Combination Landscape Lens” (1859) was one of the first, and was free from distortion, gave a flat field, and could be aplanated as a converging back lens in 1864. T. Ross introduced his “Actinic Doubles,” modified from the Collen lens, in three series —“small angle,” f/8, angle 40° to 50°; ordinary angle, f/14, angle 40° to 50°; “large aperture,” f/16, angle 80° to 90°. These lenses were similar to the “Globe,” but unsymmetrical and more rapid. The separate elements could be used alone. Some of them were fitted with a shutter near the diaphragm. They were superseded by some unsymmetrical doubles.

improvement was effected in the construction of non-distorting objectives of fairly large aperture. It consisted of two positive cemented flint menisci, each composed of a dense flint with negative focus outside and a light flint with positive focus inside, its concave surfaces facing the centre (fig. 26). This use of flint glasses alone was peculiar, former achromatic lenses having been made of flint and crown. These lenses were made in three rapidities: "Ordinary," f/6 or f/7, angle 60°; "Landscape," f/12 to f/15, angle 90°, also used in convertible series; "Wide Angle Landscape," f/20 to f/25, angle 104°; "Wide Angle Reproduction," similar to the last, but with sharper definition. The "Aplanat" had many advantages over previous doublets and the triplet, being more rapid, perfectly symmetrical, so that there was no necessity for turning them when enlarging, and free from distortion or flare. There was no chemical focus. Each component could be used alone for landscape work with double focus, subject to the ordinary defects of single lenses. By the use of Jena glasses in the "Aplanat" (fig. 27) the components of this lens were brought closer together, its intensity increased, and it was made more portable. J. H. Dallmeyer had been working in the same direction simultaneously with Steinheil, and in 1866 he brought out his "Wide Angle Rectilinear," f/15, angle 100°, made of flint and crown, the front element being cemented back (fig. 27). It was slow for ordinary purposes and was succeeded in 1867 by the well-known "Rapid Rectilinear," f/8, on the same principle as Steinheil's "Aplanat," but made of flint and crown (fig. 28). Ross's "Rapid" and Portable Symmetrical, Voigtlander's "Two flint and crown" lens, and foreign manufacture are of the same type, and still in use. They are excellent for general purposes and copying, but astigmatism is always present, and although they can be used with larger apertures than the triplets they displaced, they require clipping, and have a bad mark of positive and negative spherical aberration. The front and back lenses, by the use of Jena glasses, have been improved to work at larger apertures, and are made with three cemented elements. The Jena "Triple Achromatic," which was introduced in 1871, is composed of three separate combinations of glasses widely separated from each other. An early form of this type was made by Andrew Ross (1841) for W. H. Fox Talbot, others by F. S. Archer, J. T. Goddard (1859), T. Sutton (1860), but they never came into general use. J. H. Dallmeyer's "Triple Achromatic Lens" (1861), f/10, angle 60°, now out of date, was an excellent non-distorting lens, very useful for general work and copying (fig. 26). As made by Dallmeyer, the inner surfaces of the front and back components were slightly concave, but in T. Ross's "Acctic Triplet" (1861), f/16, they were flat. The centre lens was an achromatic negative set of novel construction, each element consisting of a plano-convex crown of high refractivity cemented to a plano-concave flint of lower about equal or higher dispersion. Both the uncorrected surfaces were spherical and concentric. At f/16 it gave sharp definition and flatness of field with freedom from astigmatism, distortion or flare over an angle of 75°. It was an excellent lens, though slow, and has been superseded by the "Homocentric" and other new rapid anastigmas. Dr. Rudolph, of Messrs. Carl Zeiss & Co., Jena, worked out in 1889 a new and successful method of constructing a photographic objective by which astigmatism of the oblique rays and the want of marginal definition due to it could be eliminated without loss of rapidity, so that a comparatively extended field could be covered with a large aperture. This he did on the principle of the opposite or opposed gradation of the refractive indices in the front and back lenses, by a combination of two dissimilar systems of single lenses cemented together, the positive element of each having in one case a higher and in the other a lower refractive index than that of the negative element with which it was associated. The front system, relied upon for the correction of spherical aberration, was made of the old glasses, a crown positive of low and a flint negative of high refractivity, whilst the back system, relied upon for the astigmatic flattening of the field, was made of the new glasses, a crown positive of high and a flint negative of low refractivity. Both systems being spherically and chromatically corrected for a large aperture, the field was flattened, the astigmatism of the one being corrected by the opposite astigmatism of the other, without destroying the flatness of the field over a large angle (see E. Jh., 1891 and 1893; M. von Rohr's Geschichte, and O. Lummer, Photographic Optics, for further details). They were issued by Messrs. Zeiss and their licensees (in England, Messrs. Ross), in 1866, in two different types. The more rapid had five lenses (fig. 31), two of ordinary glasses in the front normal achromat, and three in the back abnormal achromat, two crowns of very high refractive power, with a negative flint of very low refractive power between them. The fifth lens assisted in removing spherical aberrations of higher orders with large apertures. The second type, series IIIa, f/9, 1899 (fig. 32), had only two lenses, the functions of which were as above. These combinations could not be used separately as single lenses, which gave the ideas of "Protars" and "Satzanastigmat." In 1891 Dr. Rapoport developed himself to perfecting the single landscape lens, and constructed on the same principle a single combination of three lenses, the central one having a refractive index between the indices of the two others, and one of its cemented surfaces diverging, while the other was converging. At f/14-5 this lens gave an anastigmatic flat image with freedom from spherical aberration on or off the axis. It was, however, not brought out till 1903, as a convertible lens, or series IV, f/14, V, f/18. In 1891 Dr. Rudolph devoted himself to perfecting the single landscape lens, and constructed on the same principle a single combination of three lenses, the central one having a refractive index between the indices of the two others, and one of its cemented surfaces diverging, while the other was converging. At f/14-5 this lens gave an anastigmat image with freedom from spherical aberration on or off the axis. It was, however, not brought out till 1903, as a convertible lens, or series IV, f/14, V, f/18. In the meantime Dr. E. von Hartmann (C. B. Goetz) and Dr. A. Steinheil had also been working at the problem and had independently calculated lenses similar to Rudolph's, but, whereas he had devoted himself to perfecting the single lens, they sought more perfect correction by combining two single anastigmat lenses to form a doublet. Dr. Rudolph had had the same idea, but Messrs. Goetz secured the priority of patent in 1892, and in 1893 brought out their "Double Anastigmat," now known as ...
been made by Messrs Ross in England. Messrs Steinheil brought out their first "Orthostigmatic" in 1863, but, owing to patent difficulties, were unable to manufacture them in Germany, and they were issued later in France and England. They were followed by a second type, which has since been issued in several series by Messrs Steinheil and by Messrs Beck in England (fig. 36). According to Dr R. Steinheil (E. Jb., 1897, p. 172) this lens was an application of two principles recognized by Dr A. Steinheil as necessary for the spherical and anastigmatic correction of a lens. He attempted to carry them out in the "Antiplanet," but was prevented by the want of suitable glass. He found that for anastigmatic correction an objective should have the separating surface between two media concave towards the higher refracting medium (new achromat), and for

**Photography**

these lenses are designed to be free from diaphragm corrections, while the focal power of the negative lens is made as closely equal to the combined focal powers of the two positive lenses as may be

---

Fig. 36.—Steinheil's "Orthostigmatic" series II.

Fig. 37.—Collinear.

spherical aberration the separating surface should be convex towards the higher refracting medium. A fully corrected cemented lens cannot, therefore, be made with less than three glasses, but with uncemented lenses an air-space may form one of the media. In 1895 Dr R. Harting worked out the combination of three glasses or a single convex cemented lens, which, according to T. R. Dallmeyer, was the most perfectly corrected single lens that had been

evolved up to 1900. Dr Rudolph having succeeded in obtaining freedom from spherical aberration, and anastigmatism, and also in anastigmatic correction (Ph. Jour. 1901, 25, p. 323). In 1894 Dr Rudolph extended the application of his principle by combining the old achromat and the new achromat into a quadrant double cemented lens (fig. 38), which, according to T. R. Dallmeyer, was the most perfectly corrected single lens that had been

in 1895 Messrs Goerz patented a double anastigmat, f/5.6, with quintuple single lens components as a convertible lens, for which greater sharpness of definition and intensity, with perfect freedom from astigmatism and distortion, in the single lens, were claimed. It was invented in 1898, but, like the earlier termed quintuple of Messrs Turner & Reich (1895), it has not come into use on account of the cost and difficulty of construction. The latter firm, however, brought out in 1905 a new symmetrical quintuplet at f/6.

A triple anastigmatic combination containing remarkable new features, constructed and patented by H. D. Taylor, was issued in 1895 by Messrs Taylor, Taylor & Hobson under the name of the "Cooke Lens," and later by Messrs Voigtländer as the "Triple Anastigmatic." It consists of three single lenses, two of them positive crossed lenses of crown glass with high refraction and low dispersion, with their most convex sides outwards, and between them, in front of the diaphragm, a single biconvex of light flint (fig. 39). All

**Photography**

necessary for the flattening of the field and correcting marginal astigmatism. They are not convertible, but arrangements are made for replacing the back lens by a low-power extension lens (Ph. Jour. 1895, 19, p. 64). Series II., f/6.5 (fig. 40), and series IV., f/6, are portrait lenses. In the larger objectives of series II., the back lenses are adjustable for uniform sharp definition or a soft diffusion of focus. In a later series VI. (1907), f/6.5, this adjustment for diffusion is given to the front lens and is so arranged for portraiture that the diffusing adjustment and iris diaphragm can be operated from the back of the camera while viewing the focusing screen. A special fully corrected "Process" lens on the same general principles has recently been brought out for three-colour work and fine-line reproduction. Another distinctly new type of anastigmatic objective involving several new principles of construction was patented by H. L. Aldis in 1895, and brought out by Messrs Dallmeyer three years later, under the name of "Protar" (Ph. Jour. 1896, 20, p. 117). It also approaches the triplet construction and depends on the introduction of air-spaces between the component lenses. According to Aldis, three conditions must be observed to obtain a flat field free from marginal astigmatism: (1) The converging lenses must be of high, the diverging of low, refractive index; (2) the converging and diverging components must be separated by a considerable interval; (3) thick meniscus glasses should be used. The first "Protar" was a portrait lens, series I. It has been made in two forms, first with a single front lens, and a back negative system formed of a single thick crown lens of high refractivity with a negative cemented meniscus. In the second form (fig. 41) the front component consists of a cemented positive and negative, and both parts of the back component are cemented lenses. All the converging lenses are of baryta crown, while both the divergent lenses in the back component are a light silicate crown. It is fully corrected for spherical and chromatic aberration, free from distortion and nearly so for astigmatism, giving equal illumination over a flat field free from astigmatism of 60° Bilder's plan, with no correction of the back. Series II. (1897) is on the same principle but differs in construction, working at f/6 over an angle of 85° as a universal and convertible lens (fig. 42). The front of its construction was described by T. R. Dallmeyer in Ph. Jour. 1897, 21, p. 167. Series III., f/7.5, will at f/16 give sharp definition over a plate two sizes larger. The single components are not convertible.

In 1897 Messrs Zeiss issued the "Planar," an objective of large aperture based on the principle of the Cooke telescope objective. It is a symmetrical doublet, each element consisting of three lenses, the two inner ones being a double convex and a double concave, of equal refractive but different dispersive power, cemented together and separated by an air-space from the outer convex meniscus (fig. 43). Its special points are its good colour correction, large negative aperture and intensity, varying from f/3.6 to f/6, with perfectly defined and astigmatic flatness of field over an angle of view from 62° to 72°. It is a very rapid wide-angle lens useful for landscapes and general work, while it is also useful for portraits and groups, photo-micrograph and enlargements or reductions (see E. Jb., 1898, p. 79, Von Rohr, p. 309, and Lummer, p. 81). Apochromatic planars with reduced secondary spectrum were brought out in 1904 for three-colour photography, and are also useful for astrophotography, the circle of diffusion being very small. The "Ular" (1900), f/4.5 in the smaller and f/6.5 in the larger sizes, angle 65° and 68°, was a further improvement by Dr Rudolph. It
PHOTOGRAPHY

APPARATUS]

consists of two unsymmetrical combinations, each formed of two single lenses of very transparent glass, dense baryta crown and light flint, separated by positive and negative air-spaces (fig. 44). The separate halves cannot be used as single lenses, neither being fully corrected for colour. It is well adapted for portraits, landscapes, especially for rapid hand camera work, on account of its covering power, with freedom from astigmatism and sharp definition with large relative aperture.

Fig. 42.—Planar. Series Ia. f/4.

In 1898 Messrs Goerz patented their "Double Anastigmat Celer," series Ib, f/4.5 to f/5.5. It is a symmetrical doublet, each element consisting of two thin lenses: a positive of high and a negative of low refractive index, separated by an air-space (fig. 45). It is derived from the triplet anastigmats by decreasing the refractive power of the central convex meniscus to the refractive power of the air, so that it becomes a convex air-space between a double convex and a double concave lens. Less deeply curved surfaces can be given to the lenses, and the doublet gives anastigmatic flatness of field over an angle of 62° to 66°, equal to the best anastigmats with a still larger aperture. Series Ic, f/6.3, is similar and recommended for hand cameras, the aperture being smaller. Goerz's "Hypergon," (1900) f/22, angle 135°, is a convex back lens. It is a long-focus objective with short back focus, and is made in two forms, series II, f/6 (fig. 47), and series III, f/7.7 (fig. 48). In the latter the back element is very thin, and the front combination of infinite focal length. By discarding the symmetrical form simplicity is secured, while open or reflecting surfaces are avoided. Special attention has been paid to perfect correction of spherical aberration in the centre of the field. It is lighter, smaller and cheaper than series II. The "Duvo" lens of the same make (1907) is intended to replace the front lens and double the focus, but with less rapidity and without any loss of quality. The "Trip" (1908) is similar, but only increases the focus one and a half times and is thus more suitable for cameras of short extension. The Aldis "Oxys" anastigmat, series II, f/5.5, angle 85°, is an improved cemented doublet, in which for the air of the doublet it is free from the defects incident to air-spaces and is constructed to give more perfect correction for flatness of field with large aperture and wide angle.

It is generally stated that it is impossible to make a spherically, chromatically and anastigmatically correct photographic objective with the old optical glasses. K. Martin, of Messrs Busch of Rathenow, has, however (E. Jb., 1902, p. 68) that it is quite possible to do so with a system of separated lenses, and that it is immaterial whether the index of the lens is the same or not. An anastigmat on this principle was issued by Messrs Busch in 1902, as the "Omnar," series III, f/7.7 (fig. 49). Series II, f/5.5, angle 75°, and f/4.5, have since been issued. It is a symmetrical doublet, each element consisting of a negative flint meniscus of higher refraction, and a positive crown of lower refraction with an air-space between them in the form of a negative lens. The back element can be used alone. The "Lumar" series, by G. Rodenstock, is similar. In 1902 Messrs Ross brought out the "Homocentric," a symmetrical doublet, consisting of a negative and positive meniscus separated by an air-space (fig. 50). It is constructed so that all rains of light emanating from any one point of the object are converged again into one point in the image. It is also free from spherical zones, is not altered in focus with different diaphragms, and has no consequent part. The colour correction is so perfect that the different coloured images are identical in size and position, thus rendering it specially suitable for three-colour and process work. The back lens can be used alone, with the glasses, as a single lens of about double the focus of the doublet. It is made in several series: II, f/5.6, and III, f/6.3, for rapid and instantaneous work; IV, f/8, for ordinary purposes; V, f/6, for process work and three-colour reproduction. A later series, IV (1909) "Compound Homocentric," f/6, differs from the others in being a symmetrical doublet composed of two triple cemented elements, very close together and separated by a diaphragm. It is specially suitable for outdoor work, also for copying and enlarging, having a higher power. Zeiss's "Tessar," (fig. 51), is a rapid unsymmetrical doublet, formed of two separated uncorrected positive and negative lenses in the front element and a cemented meniscus at the back (fig. 51). The two halves cannot be used separately. The glass used is that of the lower transmissible spectrum, and it uses the secondary spectrum. Three series are made by Messers Ross, Inc.: f/3.5 for cinematographic work and portraiture, and f/4.5 for hand-camera work and portraiture; IIb, f/6.3 for general purposes, and VII, the "Homocentric Tessar," specially corrected for three-colour work and reproduction. They all give fine definition over a large flat field, free from any zonal aberration. The f/3.5 portrait lenses, with double the field and covering power of the Petzval lens, are anastigmatic and free from distortion. Messers Vogel's "Heliar," (1902) f/4.5, angle 50°, calculated by Dr. H. Harting, is a "perfect large area, suitable for portraits and very rapid instantaneous work, being well corrected for astigmatism, coma and curvature of field, with freedom from flare. It is a triplet consisting
of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (E. Jb., 1903, p. 177). The "Dynar" (1903), f/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless fens a lenses, giving brilliant sharpness and uniformity of illumination over a large angle, and is especially adapted for rapid hand-camera work.

Dr. K. Steinheil's 'Unofoc' (1903), f/4.5 is a symmetrical double element consisting of two separate lens elements of equal refractive power and of equal focus opposite signs, hence its name. Each half can be used as a single lens with small stop. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part of their correction, as explained by Conrad Beck in Ph. Journ. (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of f/4.5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs. Beck in two series: II., f/4.5, for portrait, rapid hand-camera work, telephotography and projection; and I., f/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeis's 'Euryplan' anastigmas (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a wide angle, made in four series: I., f/4.5, angle 80°; II., f/6.5, angle 90°; III., f/6.8 to 7.5, angle 82°; IV., f/5.6. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown with high refractivity and low dispersion, separated by air-spaces, each the optical centre of the same baryta crown, with its concave side towards the diaphragm. In series I., f/4.5, the two positives are placed outside (fig. 54), in series II. and III., they are inside. The single elements are fully corrected astigmatismally and chromatically, and can be used singly at double the focus (E. Jb. 1904, p. 35).

The "Isostigmat" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfill the Petzval condition that there should be two focal lengths of its individual lens multiplied by the reciprocals of their respective refractive indices should be equal to zero. Or, 2(1/4) = 0. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition the system permits of possible modifications, such as to make a more rapid lens with a shorter focal length and one-half that of a complete objective. A special feature is the excellent correction of the spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can be used also alone as diaphragms as long focus lenses of different foci (Ph. Journ. 1907, 47, p. 191). It is issued in six series: I. (1908), f/4.5, large aperture, for reflex press work and portraiture; II., f/6.5, angle 60°-65°, latter is very useful when an extended use of the rising front is required, either at a wide orpaged ordinary angle. V. (1908), f/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), f/5, with the positive lens field, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmas, but many more objectives of the kind, triple or quadruple, cemented or uncorrected, with special space, in many modifications, have been issued by English and foreign makers.

6. Telephotographic Objectives.—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive anastigmat with a negative lens, the light being picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much larger focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1865 by M. J. M. de Tournemire, and later by Dr. B. J. M. M. de Tournemire, but this system requires large and costly equipment of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principles of the "Barlow" lens, but it really goes back to the Galilean telescope (c. 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (Magia Mathematica, 1610, cap. 17). About 1607, J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (Dioptrics, Prob. cv. 1611). Christopher Scheiner made use of the same principles in his "Helioscope" for solar observations (Noua Dioptrice (1629)). W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the compound focus, which led to a convenient instrument for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France and also in England, to utilize the principle, but special lenses for this purpose were not available. Dr. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1898 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out with better precision and patented, by R. R. Gallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. A large portrait can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephoto-graphic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while...
with those of ordinary intensity the exposures are not unduly prolonged, and good definition can be obtained over an extended field.

The optical principle on which these combinations are based is very simple, and will be understood from Fig. 56. It depends mainly on the fact that in order that a real image may be thrown on the screen of an object AB, the rays proceeding from it, which pass through the positive system LA, must come to a focus at a point P within the camera. If the system LA were made divergent, falling within this limit, they will be intercepted by Ls and made less convergent, so that instead of coming to a focus at P, they will continue to converge till they reach the screen at S, and will therefore form a smaller image of the object. If the positive lens, given by the positive lens alone at f, just as stated in Kepler's problem. Moreover, this image a'b' will be of the same size as if it had been produced directly by a positive lens, LA, with a focal length equal to the effective focal length of the entire system. It can be found from the formula $F = f_1 f_2 / (f_1 - f_2)$, where $f_1$ and $f_2$ are the focal lengths of LA and Ls respectively, and $f = f_1 + f_2 - s$ being the distance between the lenses. The magnification produced by a given camera extension is obtained by dividing the latter by the focal length of the negative system, and adding one.

In its usual form (Fig. 57) the telephotographic combination consists of a quick-acting portrait lens, or an anastigmatic double of

![Fig. 57. T. R. Dallmeyer's Compound Telephotographic Lens.](image-url)

large aperture and relative intensity of suitable focal length, fitted at one end of a tube, in combination with a small pair of properly corrected negative lenses, which may vary in focus, but must be of shorter focus than the positive (usually about half); the shorter focus the greater the magnifying power for a given extension of camera, and the higher the cut-off. This combination is used for telefocal extension of focus, an object placed at the optical center 6, 9, and 13 diameters with a camera extension of 14 in. By combining the three a magnification of 30 diameters is attainable with the same advantage, which is a great advantage in many ways.

In 1908 Messrs. Zeiss issued their "Special Tele-objectives" in two sizes working at f/10, the larger with an aperture of 3.14 in. and 32 in. focal length fitted in a special "tele-camera" for plates 9 x 12 cm. These are a compound of a glass magnifying four times as finder. The smaller one, 18 in. It is recommended for half-plates with 6 in. bellows extension. They consist of specially corrected positive and negative combination with a definite focal length and requiring a single-flexible single lens of the same focal length. It is specially suitable for balloon photography, instantaneous photography, &c. The theory, construction and use of telephoto lenses has been fully described by T. R. Dallmeyer in his Telephotography.

Anachromatic Lenses. For large portrait a certain amount of softness and diffusion of the image has long been recognized by artists as desirable, and in 1898 the "Dallmeyer-Bergheim Lens" was constructed with this special object. It is composed of a single uncorrected positive meniscus front lens, with a diaphragm in front of it, and an uncorrected negative meniscus back lens. With the larger sizes it has great range of focal length on the telephotographic principle. The spherical and chromatic aberration produced by the uncorrected single lens systems of lenses within the above-mentioned limits can be overcome, and the peculiarly soft and delicate effect aimed at. It is most useful for large heads and life-size studies, the great depth of focus conducing to uniformity of definition. There is no distortion, and by stopping down to about one-third of a degree, magnification can be obtained.

It works with great brilliancy, both elements being single glasses.

It was the first of the anachromatic portrait lenses. Since 1903 Messrs. C. Puyo and L. de Pullivigny have been experimenting with achromatic telephoto combinations. In their system the same effect in portrait and landscape photography by the diffusion of focus produced by chromatic aberration, and suitable lenses of this kind have recently been brought out in Paris as Les Objectifs d'artiste. These anachromatic lenses are suitable for all kinds of studies, and are especially suitable for balloon photography, instantaneous photography, &c. The theory, construction and use of telephoto lenses has been fully described by T. R. Dallmeyer in his Telephotography.

Diaphragm Apertures. In order to regulate the intensity of the illumination by the lens, to enlarge its field, and, in the case of telephoto lenses of high magnification, to limit the area covered by the image, diaphragm apertures are used, usually with circular apertures. They are made in different ways: (1) as single metal plates, fitted into a slot in the lens tube (Waterhouse diaphragms); (2) Rotary: a single plate rotated to form various apertures, one of which is cut to fit centrally in the opening of the lens; (3) Iris: a diaphragm now very generally used, and very convenient, because it can be easily adjusted as required for intermediate apertures. In order to provide a uniform system of diaphragm apertures.
the Royal Photographic Society in 1881 drew up some rules, which were revised in 1891 and again in 1901. The former standard unit $f/4$, and the numerical notation used with it, have been abolished in favour of the unit $f/1$ established at the International Congress in Paris in 1906. Intensity ratio is defined as the quotient of the effective aperture of a lens, and not upon the diameter of the diaphragm in relation to the focal length of a lens. The effective aperture of the lens is determined as follows: The lens must be found to have a size not exceeding $1/2$ in. of the principal focal plane, and a pinhole is made in the centre of the plate (in the axis of the lens); an illuminant is placed immediately behind the pinhole itself, when the diameter of the beam emerging from the front surface of the lens may be measured. It will be found that excepting the effective aperture (the diameter of a pinhole or diaphragm) in some cases the diameter of the diaphragm itself is seldom that of the effective aperture. Every diaphragm is to be marked with its true intensity ratio as above defined, but the present intensity ratios are retained in the notation. The diaphragms are $f/6, f/8, f/10, f/16, f/22-6$, $f/32, f/45-2$, $f/64$, &c. and each diaphragm requiring double the exposure required by the preceding one. In other cases apertures are to be made in uniformity with the scale, with the exception of the highest intensity, e.g. a lens of $f/6-3$ would be more from opening the $f/8$, &c. The corresponding numbers are known as $f$ numbers, but are usually marked for a lens focused for distance. Other systems of notation are in use, but the above is generally adopted (see Fábre, T.R.P. Sciences (1891)). Special diaphragms are in use for processes worked with ruled screens (see N.S. Amstutz, *Handbook of Photography*, 1907). Standards for the screws of photographic lens flange fittings, and for the screws fitted to cameras for attachment to the stand or for movable parts, have also been laid down (Ph. Journ. 1906, 25, p. 322).

**Instantaneous Shutters.**

The general use of rapid and hand cameras and hand cameras has rendered it necessary to have some mechanical means of regulating exposures in small fractions of a second, especially for objects in rapid motion, and this instantaneous shutter has become an essential part of modern photographic equipment in many forms and patterns, shutters being of two kinds, the roller-blinds, used before or behind the lens, and the focal plane shutter, in front of and close to the plate and forming part of the back of the camera. The usual limit of rapidity of the two forms is about $1/25$ sec., but modern shutters and for ordinary purposes higher speeds are seldom required, while with the latter speeds of $1/100$ to $1/200$ sec. of a second may be attained.

Two important factors in the use of lens shutters are the rapidity of the action of the shutter, the efficiency, measured by the ratio of the time during which the shutter is fully open and the time occupied in opening and closing. Both factors are more or less variable, either with regard to the shutter as such, and also with regard to the lens and plate. The exposure of the shutter with regard to the plate and lens. In any case the efficient exposure is always less than the actual, and may be considerably so.

The proposed shutter in the following photographic moving objects is regulated by the minimum time necessary to produce a well-exposed image upon the plate, with a loss of definition, or blurring, by displacement not exceeding $1/20$, or preferably $1/30$ of the size of the object as the rate of movement of the object, the direction in which it is moving, with reference to the axis of the lens, its distance from the camera, and the focal length of the lens. It will be proportionately less as the object is more distant, the field of vision increased, and vice versa. It will be greatest when the object is moving at right angles to the axis of the lens, and least when the motion is directly towards or away from the camera. A lens of focal length $50$ ft. will support a speed of $1/100$ sec. during the exposure for an object moving $1$ m. an hour within a second, and it would require exposures between $1/4$ and $1/8$ of a second to give maximum or minimum displacements of the image between $1/20$ and $1/30$ of an inch. An object at the same distance as above would require $1$-to-10 of the above exposures. However, the distance between the object and the lens would be $1/8$ of a second. Any exposure may also be increased in the same proportion, so that the object moving to an hour at $500$ ft. distance would only require the original exposures of $1/4$ to $1/8$ of a second. On the other hand, the exposure for an object moving $1$ m. an hour within a second, of the lens would be between $1/4$ and $1/8$ of a second. This applies to the sensitivity of the plate, and the intensity and amount of light acting upon it through the lens and shutter, must be adjusted so as to produce the desired photographic effect within that time. With a lens of $8$ in. focal length the displacement would have increased in the first instance to $2-3$ in. per second, and the maximum required aperture would be from $f/16$ to $f/8$ of a diaphragm. This shows that there is an advantage in using short-focus lenses for very rapid exposures. In practice, most work of this kind is done upon quarter-plates ($4 	imes 3$ in.) with lenses of $f/4$ to $f/5$ in. focus. As the object to be photographed, or the plane through which it passes, is generally a right angle across the axis of the lens, an exposure sufficient for this purpose may be sufficient for any other. Sir William Abney has discussed this question practically in his *Instantaneous Photography*, and it is treated mathematically by W. B. Coventry in his *Technics of the Camera*, London (1907). He gives the number of changes of between the distances and limiting exposures for moving objects, allowing for a blur of $1/4$ of an inch. In foreign treatises the limit is usually calculated for a displacement of $1/4$ of a millimetre, of about $0.2$ sec. in time.

An efficient shutter should fulfil the following conditions: It should be light and compact, simple in construction and action, strongly made, and not liable to get out of order; capable of being worked with the light into the camera; easily released with a slight pressure of the finger, if a pneumatic release is not fitted, and free from any tendency to shake the camera on release. It should open and close quickly, allowing the largest possible proportion of the light to reach the plate, and being free from light leaks; not to allow any of the effective light passing through the lens, but should distribute it evenly all over the plate: though in landscape work it is an advantage to give the foreground more exposure than the sky, the exposure should be uniform over the entire photograph for prolonged or "time" exposures. With a good shutter there is less risk of shaking the camera in short "time" exposures, from $f/1$ to $1/2$ second, than there is in taking off a cap. Shutters working between $f/2$ and $f/32$, are the usual diaphragms in the lenses, and of alterations of speed while. Above all the constant in its action, giving short and variable exposures always correctly or relatively so, an important condition which cannot always be fulfilled, and the exposures marked on the indicator should be capable of being reversed at will in the darkroom, or be capable of also be adaptable for use with different lenses. Three methods of varying the speed of a shutter are in use: (1) by altering the length of the slot; (2) by the retarding action of a pneumatic brake; (3) by being released at different points. The last is in use with W. B. Coventry as far the best. They are usually released by the pressure of the finger on the end of a lever holding the moving part in a state of tension; or better, by J. Cadett's system of pneumatic pressure applied to a diaphragm, and for ordinary portraits and tube and tube, which may drive a piston acting on the lever holding the shutter, or inflate a collapsible bulb at the other end of the tube and thus exert the necessary pressure on the lever. With W. Watson's "Antinous" roller-blind, brake, and tube, and various forms of between-lens shutters. It is durable, effective and convenient (see fig. 3). In many cases both methods can be used as desired, the mechanical releasing being preferable on account of its convenience and freedom from liability to shake the camera.

The following are the principal types of instantaneous shutter: (1) Diaphragm shutter, (2) drop, (3) motion drop and flap, (4) rotary, (5) roller blind, (6) drop, and (7) the exposure central, (8) iris. They can be applied in four different positions: (a) in front of the lens; (b) centrally, near the diaphragm; (c) behind the lens (d) immediately in front of the sensitive plate. They all, however, come under two main classes: Those designed to work during the exposure, which commences and ends at the circumference of the lens aperture; and those in which the exposure begins and ends at the centre of the aperture. Some of them are lateral " in their single form and the double form in which the light is admitted at the open aperture of the shutter, relatively to the lens and plate, have a strong influence, either favourable or unfavourable, on the amount of effective light passing through the lens, and its even distribution upon the plate. The two forms of shutters completely opposite in their effect in the phases of opening and closing the aperture. It seems to be agreed that the best position for lens shutters of the lateral type is behind the objective, and for those of the central type, between the component, and the plate. The one will be illuminated during the full period of exposure, with a gradually increasing intensity, until the full opening is reached, and then the illumination gradually falls off until the shutter is closed. The most effective shutter is that which the first and the second phases of opening and closing are the shortest compared with the second phase of full opening.

With the focal plane shutters, however, different portions of the plate are exposed in succession, the lens working at its full aperture and efficiency throughout the exposure. To secure successful results in using instantaneous shutters, the operator should make himself acquainted with the working of his shutter and its efficiency in various circumstances of exposure with very different intensities. By using the bottom part of the actual value of the various exposures marked on the indicator, and

what is more important, how far they can be depended on for regularity. There are many simple ways in which the actual time of exposure from opening to closing can be ascertained sufficiently closely for practical purposes. They depend upon the measurement of the time lag on a sensitive plate by the passage of a brightly illuminated object revolving at a known speed or falling vertically through a known distance, when photographed with different speeds of the shutter against a dark background. These, and the more elaborate methods for obtaining more accurate estimations of the shutter-exposure periods and of the corresponding effective exposures — i.e., showing the actual effect of the shutter through its different phases from opening to closing — have been described by Sir William Abney in the work already mentioned, by A. Londe in La Photographie moderne and La Photographie instantanée. An apparatus for testing shutters at the National Physical Laboratory was described by J. de Graaf Hunter in the Optician, 1906.

1. Trip Shutter.—The simple flat shutter consisting of a hinged flap opening upwards in front of the lens, though favourite in early days for landscape work, and still useful for intermittent exposures or as sky-shades for securing cloud effects or increasing foreground exposures, have been largely superseded by having found in compact forms. They are used in single and double flaps for portrait and studio work, for which purpose they are made to act noiselessly and not attract the attention of the sitter. Guerry's (figs. 59 and 60) is a good example of the type.

2. Drop Shutters.—The old simple drop shutter, in which a plate having an opening in it falls in front of the lens aperture, has been superseded by the more compact and effective drop shutters, which act on much the same principle. It had a theoretical interest in connexion with the effect of different forms of aperture — circular, square, or elongated — used with shutters of the lateral type, but it is now generally recognized that a more or less extended rectangular opening, of at least the full width of the lens aperture, is best for securing the even admission of light from all parts of the image with shutters of the rectilinear lateral type, to which this and similar shutters, in which a single opening passes across the lens aperture, belong. In Busch's "sky shade" shutter (1907), facing on the front of the lens a single leaf moves vertically upwards and descends again, giving less exposure to the sky.

3. Combined Drop and Trip Shutters.—Early dry-plate days several forms of this kind of shutter were brought out, under the names of Phoenix, Phantom, &c., but are now little used. In these shutters, in addition to the drop slice, there was also a lifting flap, which on being lifted from below, and having found unobstructed the aperture, released the drop slide, which fell and closed the shutter. They were useful and effective in the smaller sizes, but heavy and cumbersome in the larger. Speed could only be estimated very roughly by the use of indin-rubber bands for giving the amount of the aperture, released the drop slide, which fell and closed the shutter.

4. Rotary Shutters.—These are of the lateral type, and consist of a circular metal disk revolving on an axis eccentric to the axis of the lens, and furnished with a radial sector-shaped opening, which passes laterally in front of the lens aperture, the plate being released when the spring is released (fig. 61). They are used in various patterns in cheap hand cameras, usually in front of the objective, and sometimes in rear, though they may be placed behind it or between the component lenses. So long as the opening is at least equal to the size of the lens aperture, the illumination is sufficiently even, but the openings are usually elongated so as to give a longer period of full opening. Working by a spring they are more portable and convenient than drop shutters. Beck's "Celverex" between-lens shutter (1906) is of this type, the disk being revolved by a spring and the variations of exposure obtained by altering the size of the opening passing over the lens aperture, and not the tension of the spring. It is speeded for exposures of \( \frac{1}{10}, \frac{1}{20}, \frac{1}{50}, \frac{1}{100} \) sec.; also "bulb" and "time." It is fairly accurate and consistent in action, but loses efficiency at the highest speeds by the diminution of the opening.

5. Roller-Blind Shutters.—For general use the well-known roller-blind shutter of the single lateral type, as made by Thorn-ton-Pickard and others, is undoubtedly one of the most popular and efficient. It possesses most of the qualities laid down as essential to a good shutter, gives good illumination, appears to be fairly regular in its action and can be used for time or instantaneous exposures. It consists of a light mahogany or aluminium box, arranged so that it can be fitted in front of or behind the objective. It is made in different sizes, and each size can be adjusted to suit the purpose of the photographer. It is also made with a disappearing cord, and in an improved pattern, the "Royal," all the fittings are inside the box. By pulling the cord

Fig. 62.—Thorn-ton-Pickard Roller-Blind Shutter with automatic exposure appliance.

an opaque black curtain with an elongated rectangular aperture is fitted for exposure from 1/50 of a second by a large hand-coiled spring on the lower roller (fig. 63). Pressure on a pneumatic bulb inflates a smaller bulb, raising the lever which releases the spring, and thus brings the blind down with a rapidity which can be adjusted by turning the hand actuating the spring, so that the corresponding speed being shown on an indicator. For time exposures, pressure on the blind opens the shutter, and another pressure closes it, and an arrangement is now made by which time exposures of \( \frac{1}{50}, \frac{1}{25}, \frac{1}{16}, \frac{1}{10}, \frac{1}{5} \) seconds can be given automatically, the pressure of the bulb opening the shutter, and closing itself, is thus prolonged. The effects of exposure required in the theory of shutters of this type has been very fully discussed by Coventry (op. cit., p. 59), who shows that for any given tension of the spring the actual exposure decreases as the size of the lens aperture diminishes, whereas the effective exposure remains constant for all apertures. This peculiarity is characteristic of the shutter. Also he shows that with plates of very different rapidities, though the exposure may be the same, the actual exposure effective in less than the rate and a small stop for the slow plate and a large stop; consequently the blur due to the movement of the object would be proportionately less on the rapid plate than on the slow one. Also for any given lens the shutter the more rapid the exposure can be made, though with the same lens a larger shutter is capable of giving a more efficient though less rapid exposure. It is better, therefore, for moderate exposures, to have a larger shutter than the size of the lens requires. Sir William Abney had given diagrams of the action of a shutter of this kind in his book referred to; they show clearly that the centre of the plate gets more exposure than the margins; but practically this is not very noticeable, and the action is very regular.

tensions of the springs. Thus the new Goerz-Anschütz shutter has ten tensions and nine curtain apertures, providing for ninety different speeds or exposures, ranging from \(1\) to \(1\) of a second, besides automatic exposures from \(1\) to \(5\) seconds and time exposures (fig. 64). Most of these shutters are now provided with a self-capping device for protecting the sensitive plate during the setting of the shutter. As the slit moves in the plane of the plate, if it is too narrow or moving too slowly, it may cause distortion of the images of objects on the plate, especially if near the camera, but with due care in regulating the width of the slit and the movement, this is practically not often perceptible, especially if the slit is arranged to move in the same direction as the object.

**Fig. 64.—Goerz-Anschütz Focal Plane Shutter.**

The theory of these shutters is discussed by Coventry (op. cit. p. 56), more fully by Fabre (T. E. P. Suppl., p. 128), and their practical use in Focal Plane Photography ("Photo-Miniature Series," No. 77, 1907).

7. Moving Blade Central Shutters.—These shutters, in which two thin metal or ebonite plates or opaque curtains with round or rectangular apertures, or in other cases two curved blades, pass very quickly over each other in opposite directions, are largely used in many patterns fitted between the lenses of combination or attached to them in front or behind. Formed of two single lateral shutters opening and closing in the centre of the lens aperture, they become central, the exposure taking place during the short period between the passing of each other or the curved blades opening out and closing again. To obtain the greatest efficiency the size of the openings should correspond with the full aperture of the lens. If each plate moves as fast as a drop shutter the combination gives double the speed of the strip opening and closing the exposure. The sensitive plate will be most evenly and strongly illuminated when the leaves of the shutter work inside the lens near the diaphragm, as in Bausch and Lomb’s "Unicum" and other similar between-lens shutters, in general use. This necessitates the fitting of the lens to the shutter, but with adapters

**Fig. 65.—Bausch and Lomb’s "Unicum" Shutter.**

**Fig. 66.—Lancaster’s "See-Saw" Shutter.**

it is possible to fit other lenses. Some forms are, however, suitable for use in front of the lens, such as the "Camera" Hunter and the "See-Saw" (fig. 66), while those of the double-roller-blind type can be used either in front of or behind the lens, though this position is not a favourable one. In these the rectangular form of aperture is the best, circular apertures cut off too good deal of light, as in the case of drop shutters. W. B. Coventry (op. cit. p. 60) has discussed the action of the double-roller-blind shutter as typical of the central classes of shutters, and shows that while, under similar conditions, with the lateral shutter the effective exposure is constant and the actual exposure variable at all apertures, it is the reverse with the central shutters, and it will not be so easy to calculate exposures with different sized stops. A central shutter, acting as a diaphragm of variable size, permits more accurate exposure than a lateral shutter of the same dimensions, as long as the opening of the lens is greater than the lens aperture, the coefficient of illumination of the lens varying as long as the shutter opening is smaller than that of the diaphragm used. It is desirable, therefore, to increase the speed and use as large an aperture as possible, so that the diaphragm used may be entirely uncovered during the greater part of the exposure.

8. Iris Shutters.—These are a further development of the double curved blade central shutters, and constructed on the principle of the "Iris" diaphragm, with several leaves opening out from the centre of the lens and closing again. They are usually fitted to the rear of lenses of various sizes, and can be made very light and compact. Theoretically this central position of the shutter is the best, and the "Iris" is the best form for ensuring the most equal distribution of light over the plate, provided, as stated above, that the openings to the full aperture of the lens. They are made so that the periods of opening and closing may be as short as possible compared with that of the diaphragm. These shutters are fitted in construction and fitting to the lens, and so are expensive. They can, however, be used with several sets of lenses of varying apertures, each foc fitting the same mount. Several forms are made by British and foreign makers, with three, four or even five blades (fig. 67) for general use, or for use in front of cameras for telephoto work. Further details regarding the different forms of shutters, theoretical and practical, will be found in the works of Abney, Coventry, Eder, Fabre and Londe.

**Fig. 67.—Goerz’s "Sector" Shutter.**

**Exposure Meters.**

When gelatin dry plates came into general use, and were made of many different degrees of sensitiveness, the want of a guide to the proper exposure for the various makes of plates under different conditions of lighting began to be felt, and several methods were devised for meeting it. Some of them depend solely upon data obtained from observations of the action of the principal factors affecting the result, namely: (1) the speed of the plate; (2) the actinic power of the sun’s light for the time of year in a given latitude and position at the particular time of day; (3) the speed of the diaphragm and lens, and the time of exposure; and (4) the subject and its illumination as affected by local and atmospheric conditions. With others these data are supplemented by, and practically based upon, actinometric observations of the action of the light, or *sensitiveness* of the plate, upon the various conditions of exposure. Methods of obtaining these data by instruments which are based, together with carefully-recorded observations of the combined working of his lenses, shutters, plates and methods of development under the various combinations of conditions, or a *sensitometer*, are necessary for knowing approximately the relative sensitiveness or "speed" of the plate in use. In the early days of gelatin dry plates their rapidities were stated as so many times those of wet plates, or (as in the phrase) a "sensitivity," "rapid" or "extra-rapid," terms which, though suitable for one make of plate, may not be so for others. This was improved upon by the adoption, in 1878, of Leon Warnerke’s "Sensitometer," which was in the system by V. C. Driffield, published in 1893, as No. 60 of the "Photo-Miniature Series." It is a simple scale of 25 squares of different intensities, marked with opaque numbers and arranged so that each third number indicated a doubled rapidity. This was placed in a frame in front of the sensitive plate, and exposed for thirty seconds to the current of light emitted by a phosphorescent tablet, supplied with the instrument, which was previously excited by burning one inch of magnesium ribbon in front of it. The exposed plate was then developed, fixed, and the highest number indicated the rapidity of the plate. By this means many plates were developed and compared in one day and a half, with very much less trouble than the methods described, and with a fixed period of standard methods of evaluation. The scale and its values have been published in the *Journal of the Society for Chemical Industry* (1890, 1891), and later ones in the *Photographic Journal* (1898). A complete account of the system is given by V. C. Driffield, *Photographic Journal*, 1897, as No. 58 of the "Photo-Miniature Series." The sensitiveness shown on the plate, *H. & D. scale is directly proportional to the speed number given. The method has been adopted by several dry-plate makers in...
denoting the sensitiveness of their different brands, and is more or less the basis on which the plate-speeds for the modern English dry-plate actinometers and exposure meters are calculated. Several systems of photometry and measurement of the speeds of dry plates have been discussed at the meetings of the Congrès International de Photographie, in 1889, 1891, 1900 and 1905, but no definite standard has been finally adopted. In Germany the use of J. Scheiner's sensitometer has been adopted, and appears to be extensively used. It is based on a system of photographing non-sensitized tints given by rotating sectors. A full account of the instrument, and of a system of sensitometry based on its use, is given by J. Eder in the Almanac photographique (1906) p. 456, and (1909) p. 227. In 1901 Chapman Jones brought out a convenient plate-tester on the same principle as the Warmerke sensitometer, but extended by the addition of a colour sensitometer, which is useful for the evaluation of chromatic dry-plate tints, colour screens, light filters, &c. It consists of a screen plate, 41 x 33 in., containing a series of twenty-five tints of graduated densities; a series of coloured squares, blue, green, yellow and red, and a neutral grey, all five being approximately equal luminosity; a series of four squares of special pure colours, each representing a definite portion of the spectrum; also a space of line design, over which is superposed a half-tone negative. To use the instrument, a quarter-plate of the brand to be tested is exposed behind the screen for a few seconds to the light of a standard candle placed at the distance of a foot, developed, fixed and washed. An examination of the plate will show the sensitiveness, range of grain, amount of halation, and the most suitable light for development. It can be used for many other tests, and enables any brand of plates to be readily tested by the user and compared with another standard he may have procured. In making these and similar tests, a standard developer should be allowed to act for a fixed period and at a uniform temperature (Ph. Journ., 1901, 25, p. 246).

The most important factor is the actinic power of the light. It depends normally on the height of the sun for the latitude of the place at the time when the photograph is taken, and exposures in bright sunlight are found to vary approximately as the cosecant of the sun's altitude above the horizon. The height of the sun itself is found at any given time of the year by the observer, but is liable to more or less local and temporary diminution by the amount of cloud, haze, dust, &c., present in the atmosphere at the time. It is also affected by the time of day, increasing from sunrise to noon, and then decreasing to sunset. The remaining factor is the effective diaphragm aperture of the lens in relation to its focal length. In most cases of ordinary outdoor exposures this can be taken as its normal size, but becomes a factor in the exposure if the focal length is much increased for photographing near objects. Besides these principal factors, the nature and colour of the objects, their distance, and the amount of light received and reflected by them under various atmospheric conditions have a great influence on the exposure required. W. B. Convery has shown (op. cit. p. 75) how the "light coefficient", for full sunlight, can be found, and has given a table of values of L for the latitude of London by hour of the day in period of ten days throughout the year, also the relative coefficients for "diffused light," "cloudy," "dull" and "very dull." Tables of exposures for different subjects under varying conditions of light have been published by F. M. Mills, W. T. Helper, J. A. Scott, and others, and in preparing them Dr J. A. Scott's tables, showing monthly and daily variations of light for countries near N. lat. 53°, are generally used. The more modern tables, such as are published in the printed "exposure notebooks," also take into account the plate speeds, but unfortunately there is no uniform standard of plate speeds, owing to the difficulty of fixing a definite standard of light. The subject is fully treated in the British Journ. Phot. 1906, 3, 575; H. Borel, "Le Calcul du temps de pose en photographie," and similar works by A. de la Baume Pluvaini, G. C. d'Espinassoux and others.

Based on the same principle as these exposure tables, various portable exposure meters have been brought out, in which scales representing the coefficient for plate-speeds and diaphragm are arranged as in a slide rule, so that, when properly set, the normal exposure required can be read by inspection, and calculated by them under various circumstances. In Hurter and Driffield's "Actinographe" the light coefficient is given on a printed card showing the curves for every day in the year and for every hour of the day, the unit being the 14th part of the brightest plate exposure and needed daylight when the sun is at its zenith. A "lens" scale shows the ratio of aperture to focal length in general use, and is calculated for single, double and triple systems of lenses. The "speed" scale is based on the exposure in seconds which will produce a definite degree of grey with the given actinic power of light and a certain diaphragm of an ordinary landscape. An additional scale is given for five different degrees of illumination—"very bright," "bright," "mean," "dull," "very dull." A table of factors for "views," "portraits," "interiors," "copying," is also given, and these regulate the figure to be taken for the exposure. The scales are engraved on boxwood, and there are two sliding frames (fig. 68).

It is specially adapted for use with plates of speed numbers agreeing with the H. & D. scale, but can be used with any plate of which the relative speed number is known. Convenient exposure meters have been made since 1890 by A. Watkins, of Hereford, in different forms based upon an actinometrical test of the light at the time of exposure. In the complete "Standard Meter" (1909) scales corresponding to "speed of plate," "diaphragm f numbers," "light," "subject" and "enlarging," made by R. D. Ayres, are arranged on rings adjustable round a cylinder. The plate-speeds are taken from a table and the "light coefficient," or "actinometer number," is ascertained at the time by exposing a piece of sensitometric paper in the actinometer at the end of the instrument for the number of seconds required to match a fixed tint as shown by an attached pendulum. Many improvements have been made in it and the latest pattern (1908) is made in magnesium (fig. 69). The "Dial meter" (1901) is a simpler form in a circular metal case with four apertures, marked "no plate," "stop," "act" and "exp." above the corresponding scales, and an actinometer for testing the light. The numbers showing the speed of the plate in the f value of the diaphragm, and the actinometer exposure in seconds are brought into the respective apertures and the exposure required is read off in the "exposure" aperture.

An "indoor meter" is also made, and a "hand camera calculator" for use with the "Standard" meter. The "Queen Bee" and "Bee" meters (1903) are later, smaller and more convenient instruments which have superseded the "Dial meter and have the number numbers and exposures marked round the case, and the scales of f numbers" and "light" on a revolving glass plate. This is revolved till the f number on the right is opposite the speed number of the plate; opposite the "actinometer number" on the left, found as above, will be found the corresponding exposure in seconds (fig. 70). The "Queen Bee" meter is similar to the "Bee," but of better construction and fitted with a magnifying lens.

G. F. Wynn's "Infallible" meter (1893) is also in dial form, but the sensitive paper is exposed directly, no pendulum is used, and the scales are open on the dial. In use, the glass carrying the movable scale is turned until the actinometer time in seconds upon the exposure scale is opposite the diaphragm number of the plate, as given in the list of plate speeds; the correct exposure will then be found against each stop given on the scale. There are practically only two scales: the scale of diaphragms representing the diaphragm apertures or f numbers, the speed of plate and the variation of exposure due to subject; and the time scale, representing the actinometer time and the exposure (fig. 71). The actinometer is protected by a yellow glass screen when not in use. In a smaller form the scales are on the

APPARATUS

518

Self-developing dry plates were introduced in 1906, in which the developing agent is mixed in the film itself, as in the Ilford "Amauto" plate, which only requires immersion in a solution of washing soda for development, or, as in the Wellington "Watalus" plate, which only requires exposure to be developed. The advantages required for development, this application also preventing halation. The slow plates used for producing lantern slides and transparencies are usually prepared with an emulsion of silver chloride with or without albumen, or with gelatine.

The rendering of photographic plates isochromatic or sensitive to all colours by dyeing them with eosin, or other suitable dyes, has been greatly improved by the use of new dyes, especially McRae's "interpositive" plate, and by papers containing dyes such as the Hoechst factory, and known as "orthochrom T", "diazobenzine", "pinaverol", "pinacrom" and "pinacyanol", the latter of which can confer on a silver bromide plate as high a degree of isochromatics or red as it can for yellow; also F. Bayer's "Heliplan", Dr. Mischke's "cyclic chrom", and A. F. W. Du Cane's "347" (see E. Jb., 1905, pp. 183, 336). Panchromatic plates are now largely manufactured and used for all photographic work in which the rendering of the relative colour luminosities is essential, and more particularly in the case of colour photome- try, methods of conjugate two or three plates, in which the plates are required to be sensitive to red, green and blue-violet. They are made in different degrees of general and colour sensitivity, according to the purpose for which they are required, and may be used with thermoplastic plates for the sensitisation of the plates made of coloured glass, or glass coated with coloured gelatin, collodion, &c., or with glass cells containing solutions of suitable dyes or salts. For the various processes of three-colour reproduction, special plates and diazoichromatic or trichromatic filters have to be used for taking the three negatives, their intensities and absorptions being accurately adjusted to the particular plates in use; the same applies, but less strictly, to the yellow screens and to the printing plates. The latter metals, yellow screens, for these colour-filters have been prepared by Dr. E. König. Various kinds of colour screens for ordinary, microscopic and trichromatic work are made commercially, and Messrs. Schott of Jena make a special colour screen.

Plates for Colour Photography.—In 1868 Louis Ducos du Hauron, among various trichromatic methods patented for photographically reproducing coloured objects in the colours of nature, described one in which the trichromatic plates were prepared for the photographer to prepare his own plates, nor, indeed, could he do so with any advantage. The practice of outdoor and studio photography has thus been very much simplified; and although with a suitably arranged set of lights a trichromatic result is produced without the necessity of the photographer having to keep in mind the relative strength of the three lights, or the number of one for taking and another for viewing, and the cost of making them (B. J. A., 1899, p. 671). The "Florence" chromatic plate (1895), worked out in America by J. H. Fowle and Florence Fowle, consists of three emulsions of different colours, the three plates being photographically printed on a glass plate, coated with panchromatic emulsion and exposed to the coloured object through the screen (Penrose Pictorial Annual, 1908-1909, p. 111). Some other plates have been described by J. W. McDonough and J. Joly for various methods of preparing trichromatic ruled screens (Ph. Journ., 1900, p. 191). The Joly method was fairly successful in action, but had several disadvantages owing to the complexity of the apparatus. The "König" method, one for taking and another for viewing, and the cost of making the plates (B. J. A., 1899, p. 671). The "Florence" chromatic plate (1895), worked out in America by J. H. Fowle and Florence Fowle, consists of three emulsions of different colours, the three plates being photographically printed on a glass plate, coated with panchromatic emulsion and exposed to the coloured object through the screen (Penrose Pictorial Annual, 1908-1909, p. 111).

After several years of laborious research, Messrs. Lumière, of Lyons, adopting Ducos du Hauron's coloured grain method, succeeded where he had failed, in 1907 brought out their Autochrome plates. The process consists in coating the plates with a sensitised gelatine emulsion, stained violet, green and orange, the interstices being filled with fine carbon powder to form a tricolour screen, dark reflected and of a pinkish, nearly appearance by transmitted light. This when exposed, and developed in a so-called panchromatic emulsion of gelatine-silver bromide. The plates are exposed in the camera from the back, through the tricolour filters, using also a special compensating orange-yellow screen, before or behind the lens, then developed as usual, producing a new colour image in the concomitant colours, which is then treated and reversed so as to produce a positive coloured image by transmission, showing the picture in its proper colours. The results thus obtained...
PHOTOGRAPHY

are remarkably good and practically solve the problem of direct colour photography in a simple and fairly inexpensive manner (see *Agenda Lumière*, 1909).

In C. L. Finlay's "Thames" color plates (1907), the colored screen was a network of circular dots coloured alternately orange-red and green and the intermediate spaces blue. It is used alone, the coated surface being placed in contact with a panchromatic plate, the uncoated side towards the lens. It carries register marks of a tracing which, on superposition, may both reveal and reverse the image. These screens, being more transparent than the "Autochrome," require less exposure, but the colour rendering is not so perfect. In the Jougla "Omnicolore" plates, the colored screen and the panchromatic plate are in contact, one plate as in the "Autochrome," but the screen is made up of a series of blue-violet parallel lines, with intermediate alternate lines of orange-red and yellowish-green at right angles to them. In the Schöffer "Trichrom" plates, the sizes of the colored dots in the three plates are approximately:

- "Autochrome" starch grains: 12 to 24 in.
- "Thames" plate, dots, diameter: 4 in.
- "Omnicolore" plates, blue line: 2
- red square: 1

E. Fenske's "Aurora" plates are a tricolour emulsion formed by coating a glass plate with a mixture of finely divided particles of gelatin, dyed orange-red, green and blue-violet, without any intervening spaces. The grain generally is coarser and more irregular than in the "Autochrome" plates, but optically corresponds to that of the "Thames." This screen does. These plates are issued uncoated for use with any suitable panchromatic plate. A later process is due to Dutay. With the exception of the "Autochrome," these processes are still inappreciable.

**Celluloid Films.** In order to avoid the weight of glass plates, which may become burdensome on a tour, and also the risk of breakage of valuable records, thin films or sheets of celluloid coated with sensi- emulsions can be used, with great saving of bulk and weight and no loss of efficiency, though such films are sometimes liable to deterioration by long keeping before or after exposure. They are made in two thicknesses, stiff or flexible, the stiff being used exactly as plates, the flexible being backed with a card or glass plate, while the flexible are made up in separate sheets with cardboard backing, as in the Kodoid films, or in convenient packages of twelve or more in film packs of varying sizes. Flexible films intended for permanent use are generally held in a frame or an unrollable. Light and other effects of the process have for many years past also been prepared. In long strips of different widths suitable for use in hand cameras of the Kodak types and in roll-holders. In the early forms of roll-holders the film were used alone, being unrolled from the drum by a perforated roll, but, as already stated, they now supplied on spools in cartridges which can be changed in daylight. C. Silly seems to have been the first to employ this method in 1879. In these cartridges the film is provided in a strip which, long enough to pass up through the camera, is wound on a spool and passed into the camera through a slit in the top of the cartridge, the film then being drawn off the spool by the guide rollers and wound on to the cap of the camera. The camera is opened to expose, and is then closed for developing. Each exposure is made by pressing a button in the top of the camera, which is then opened again to expose the next frame. The film is then rewound in the cartridge before being opened to expose the next frame. This method has been improved and is in use, and is used for a great variety of purposes.
The "calculator" can be used with any ordinary clock or watch, but the "dark-room clock" (fig. 73) has been specially constructed for the factorial system. It is an improvement on the earlier forms of Watkins' "Elkrometer," and has a 4 in. dial with 10 minute and 1 second divisions, very plain and dark, with a centre second hand, stop action and outside indicator to mark the completed time. The second hand completes the revolution in 100 seconds, while the minute hand does so in 10 minutes, or sufficient for the ordinary development, though, if necessary, very much longer, both hands starting together always at 0.

In 1908 Watkins brought out another system of "thermo-photography" by the aid of a "standard developer," the duration of the development, at a given temperature, being modified according to the make and speed of the particular plate in use. The temperature variations are indicated by a second hand. The "rapidometer" or "Elkrometer," measurement by the developer, the variations for development speed of various plates, being given approximately on the "Watkins' Plate Speed List," which thus shows the "speed of plate" and "speed of development." It is more adapted for plates, films and stand development in tanks or machines, no observation of the plate being required, and the times are most conveniently observed with the "dark-room clock." Full details of these two distinct methods of development will be found in the 4th edition of the Watkins' Manual of Exposure and Development.

C. W. Piper's "photographer's stop clock" (1906) is a more elaborate clock, intended for use not only in "time development" but also for ordinary divisions, very plain for dark rooms in regard to time is of importance. It is fitted with a gong and arranged to work by "time" or "bulk." Once started, by pressure on the lever or on the bulb, it will continue to go until stopped, starting again at the completion of every hour, or when the second hand reaches the zero point. A second pressure on the bulb stops the clock, so long as the pressure is continued, while pressure on a lever stops it permanently. It is thus useful for timing any intermittent operations, whilst the clock adds up to separate times and prevents the occurrence of errors difficult to avoid when timing with an ordinary watch. By an additional attachment a prolonged time exposure with the camera may be terminated, or when the instantaneous or short time exposure is given at any prearranged time. Messrs Houghton's "Ensign" clock for time development has a dial with 60 divisions, a single hand, and is fitted with a gong. It can be set to ring an alarm bell at the expiration of any time, the completion of every hour, can be started or stopped immediately and is easily read in the dark-room. It requires no wind-up, the action of setting providing the tension for the recording movements. It can be stopped and started at will and the bell arranged to give a short or prolonged ring.

S. Stanley's is another convenient form, with a 4½ in. dial, divided into 60 seconds and 60 minutes, the thick hand recording the seconds and the thin hand the minutes.

Several forms of developing tanks and machines have been constructed for developing a number of exposed plates, together with ordinary or dilute developers, with the aid of the factorial system or independently of it. The Kodak Automatic Developing Tank (1905) is a useful arrangement by which bands of exposed roll films can be developed in daylight, without any need of a dark-room (fig. 74). The exposed film is wound from the spool...

III.—PICTORIAL PHOTOGRAPHY

Pictorial photography differs from other branches of photographic practice in the motive by which it is prompted. Employing the same methods and tools, it seeks to use photographic processes as a means of personal artistic expression. Thus in the early days of Fox Talbot’s calotype, about 1846, David Octavius Hill, a successful Scottish painter, took up this method of portrayal, and, guided by an artist’s knowledge and taste, and unfettered by photographic convention, which indeed had then scarcely begun to grow, produced portraits which for genuine pictorial quality have perhaps never been surpassed, especially if some allowance be made for the necessary imperfections of the "Talbotype" (see Plate II). Whether they were in their day typical examples of Talbotype with all the latest improvements, Hill probably never cared. When, again, a few years later, Sir William J. Newton, the eminent miniature painter, read a paper before the newly formed Photographic Society of Great Britain (now the Royal Photographic Society), his recommendation to depart from the custom of defining everything with excessive sharpness caused his address to be almost epoch-making. "I do not conceive it to be necessary or desirable," he said, "for an artist to represent, or aim at, the attainment of every minute detail, but to endeavour at producing a broad and general effect. . . . I do not consider that the whole of the subject should be what is called ‘in focus’; on the contrary, I had found in many instances that the object is better obtained by the whole subject being a little out of focus." The doctrine has been persistently repeated ever since, but only within the last decade of the 19th century was the suppression or diffusion of focus received by photographers generally with anything better than ridicule or contempt, because it was unorthodox. O. G. Rejlander, Mrs Julia Margaret Cameron, H. P. Robinson, and others, by precept or practice, strove against such photographic conventions as had arisen out of those technical exigencies to which pictorial qualities were so often sacrificed. As late as 1868, in the Manual of Photographic Manipulation, by Lake Price, the old advice to arrange a group of persons in contour form, so as to adapt the subject to the curve of the field of the lens, was repeated with the additional recommendation of plotting out on the glass beforehand the "curve of the focus" as a guide. As a defiance of this dictum, Rejlander, in 1869, produced a group of the members of the Solar Club in which some of the chief figures were set widely out of the "curve of the focus." The mere technical difficulties of this performance with wet collodion plates, and in an ordinary upper room, need not be touched upon here, but it is to be noted as one of those triumphant departures from convention which have marked the progressive stages of pictorial photography. At about the same period, Mrs Cameron, carrying the recommendation of "a little out of focus" rather far, and regardless of how her lens was intended to be used by its maker, secured the rendering dictated by her own taste and judgment, with the result that many of her portraits, as those of Tennison, Carlyle, &c., are still in their way unsur-
passed. Contemporaneously, Adam Salomon, a talented sculp-
tor, "sunned" down the too garish lights of his photographic prints, and strengthened the high lights by working on the back of the negative.

But, during the concluding quarter of the 19th century, probably the most powerful influence in pictorial photography was that of H. P. Robinson, who died in February 1901, and, but for a brief period about the year 1875, was one of the most prolific "picture makers." Inspired by Rejlander, of whom he was a contemporary, Robinson will perhaps be best remembered by his earlier advocacy of combination printing. As early as 1855 Berwick and Annan exhibited a photograph which was the result of printing from more than one negative, a figure from one plate being cunningly introduced into a landscape print from another. Then came from Rejlander "The Two Ways of Life," in which, with wonderful ingenuity, thirty different negatives were combined. Robinson followed, and between 1858 and 1887 produced a considerable number of combination-printing, one of the most popular and fairly typical examples being "Carolling" (see Plate II), which received a medal in the exhibition of the Royal Photographic Society in 1887.

Though in this combination-printing one may perhaps perceive the germ of incentive towards the production of special effects not seen in the original, yet the practice was not destined to become very popular, for even in the most capable hands there remains the difficulty, if not impossibility, of fitting a portion of one negative into a print from another and still preserving true relative tonality, and even true proportion. Skillfully produced, eminently popular in character though "Carolling" may be, such errors are not absent. Of this combination-printing Dr P. H. Emerson has said: "Cloud printing is the simplest form of combination-printing, and the only one admissible when we are considering artistic work. Rejlander, however, in the early days of photography, tried to make pictures by combination-printing. This process is really what many of us practised in the nursery, that is, cutting out figures and pasting them into white spaces left for that purpose in the picture-book. With all the ease and beauty of the world the very best artist living could not do this satisfactorily. Nature is so subtle that it is impossible to do this sort of patchwork and represent her. Even if the greater truths be registered, the lesser truths, still important, cannot be obtained, and the softness of outline is easily lost. The relation of the figure to the landscape can never be truly represented in this manner, for all subtle modelling of the contour of the figure is lost."

Pictorial photography received a large accession of votaries in consequence of the greater facilities offered by the introduction of the gelatino-bromide, or dry-plate, process, which, although dating from 1880, did not notably affect photographic communities until some years afterwards; and although improvement in appliances and instruments had little to do with the advance of the pictorial side of photography, yet, indirectly at least, the dry-plate and the platinotype printing process have had an undoubted effect. The former gave enormously increased facility, and dispensed with tedious manipulations and chemical knowledge, while its increased light-sensitivity decreased the limitations as to subjects and effects. The platinotype process was discovered in 1874–75 by W. Willis, who employed his chemical skill and knowledge to give the world a printing process more likely than the hitherto prevalent silver papers to satisfy artistic requirements.

Up to 1882 but few outdoor photographers had ventured to run counter to the general dictum that photographs should only be taken during sunshine or good bright light, and unquestioning
PHOTOGRAPHY

Aroused into greater activity by these events, the Royal Photographic Society began to pay more attention to what had now become the more popular phase. At subsequent exhibitions the technical and scientific work was hung separately from the "Art Section," and a separate set of judges was elected for each section. It became the custom to allot by far the greater amount of space to the "artistic"; and, later, artists were elected as judges, by way of encouraging those who were devoted to the pictorial side to send in for exhibition. In the autumn of 1900 the New Gallery was secured, and a comprehensive exhibition of all phases of photography was held.

It is interesting to note that as a distinct movement pictorial photography is essentially of British origin, and this is shown by the manner in which organized photographic bodies in Vienna, Brussels, Paris, St Petersburg, Florence and other European cities, as well as in Philadelphia, Chicago, &c., followed the example of London, held exhibitions on exactly similar lines to those of the London Photographic Salon, and invited known British exhibitors to contribute. The international character of the Salon encouraged an interchange of works between British and foreign photographers, and the productions of certain French, Austrian and American photographers are perfectly familiar in Great Britain. This, in the year 1900, led to a very remarkable cult calling itself "The New American School," which had a powerful influence on contemporaries in Great Britain.

It may be well to glance at such improvements of process or apparatus as have not been direct and essential means to pictorial advance, but rather modifications and improvements made in response to the requirements of the artistic aspirant. Such improvements are of two orders—those which aim at securing greater accuracy of delineation, the correction of distortion and of apparent exaggeration of perspective, and the more truthful rendering of relative values and tones; and those which were designed to give the artist the satisfaction of being able to dispense with the lens altogether, or even to employ a minute aperture, technically called "a pinhole." This is but one example of many which might be quoted to bear out the statement that in photography the advance of anything in the nature of artistic qualities has not been in consequence of mechanical improvements. The hand camera can only be said to have had an indirect influence: it has increased the photographer's facilities, it has made it more easy to take the photograph, but it has not, perhaps, come to any considerable extent, and in the hands of the truly artistic, it has been little if at all used.

Meanwhile the Photographic Society of Great Britain had drifted away from its artistic starting-point, and had become chiefly absorbed in purely scientific and technical subjects. But the general apathy which existed in respect of the artistic aspirations of some workers was the forerunner of a period of renaissance which was to end in lifting the pictorial side of photography into a greatly improved position. In 1886 Dr. P. H. Emerson read before the Camera Club a paper on "Naturalistic Photography," which served as an introduction to the publication (1887) of his book under that title. Unquestionably this book struck a powerful blow at the many conventionalities which had grown up in the practice of photography; the chief doctrines set forth being the differentiation of focus in different planes, a more complete recognition and truer rendering of "tone," a kind of truthful impressionism derived from a close study and general acquaintance of nature, and a generally higher and more intellectual standard. After the publication of a second edition in 1888 Dr. Emerson publicly denounced the views he had published, by issuing in January of 1891 a bitterly worded, black-bordered pamphlet, entitled "The Death of Naturalistic Photography." But the thoughts which the book had sowed were not to be stilled by its withdrawal. Towards the end of the same year the conflict which was within the Photographic Society had become apparent, and that same year saw the establishment of the branch of photography which was to have such an important history. The hanging of certain photographs at the exhibition of that year, and a number of prominent members resigning their membership as a protest against the lack of sympathy and the insufficient manner in which pictorial work was represented and encouraged. This secession was to prove the most important event in the history of that branch of photography. The secessionists being among the most popular contributors to the annual exhibition gathered round them numerous sympathizers. In the following year they formed themselves into a brotherhood called "The Linked Ring," and in 1893 held their first "Photographic Salon," at the Dudley Gallery, Piccadilly. The most noteworthy of the early adherents attracted to the new body was James Craig Annan, whose work was practically unknown until he exhibited it at the first Salon; and almost at once he, by general consent, took a position amongst pictorial photographers second to none (see Plate II).
PHOTOGRAPHY, CELESTIAL

The requisites for celestial photography are best explained by a comparison with ordinary photography in several essential points.

a. Illumination.—In taking a portrait artificial light is used, being thrown on to the face of the sitter either directly or by reflection. If the day is dull a longer exposure is required, and artificial light may be used when the daylight fails. In photographing the stars there is no question of illuminating them by artificial light; for the strongest searchlight which we could throw in the direction of the heavenly bodies would have no sensible effect. The light used is their own, and its feebleness renders it necessary to make long exposures, the length increasing as we attempt to get images of fainter objects. The invention of the dry plate, by making it possible to give very long exposures, caused a revolution in celestial photography. With the wet plate, exposures were limited to the few minutes during which the film would remain wet; but the few minutes required in the telescope for days, weeks or even years if necessary. On the approach of daylight, the cap is put on the camera, or the plate removed into the dark room; but when night returns the plate is put back in the telescope, which is accurately pointed to the same stars, the cap is removed, and the exposure is resumed without any loss from the interruption.

b. Magnification.—In taking a portrait we can obtain a large or small size by placing the camera near the sitter or far away. But this method is not available for the heavenly bodies, since we cannot sensibly approach them. To magnify an image we must lengthen the focus of the camera, either directly or indirectly. The direct method is to construct a lens or mirror of long focus; the camera becomes similar in length to a telescope; and indeed resembles a telescope in other respects, except that we take away the eye-piece and put in a photographic plate instead. However, we already have a lens of short focus which we wish to use, we may lengthen the focus indirectly by using a secondary magnifier, that is by putting in another lens near the focus of the first. In either case the profitable magnification is limited, not only by the imperfections of the optical apparatus but by disturbances in the atmosphere. Air currents, either outside or inside the telescope, act as irregular lenses of varying shape, and produce such defects in the image that we gain nothing by enlarging it beyond a certain point. Such air disturbances do not trouble the ordinary photographer at all, or scarcely at all; he is only concerned with a few feet of air, whereas the celestial photographer cannot escape from the necessity of looking through many miles of it.

c. Steadiness.—In taking a portrait the photographer is only concerned to fix his camera firmly and to induce his sitter to remain still. The heavenly bodies are in constant motion, though their real and apparent movements are fortunately smooth, except for air disturbances above mentioned. If, therefore, we were to devise perfectly smooth clockwork, we could keep the camera or telescope continually pointed to the required star or stars. But human workmanship has not yet made clockwork of sufficient strength and accuracy to keep a large telescope satisfactorily pointed. The clockwork which had been found good enough for use with visual telescopes was soon found to be quite inadequate for photography. The first method adopted was to bound two telescopes, one visual and the other photographic, firmly together; and by looking through the visual one to keep some object steadily on the crosswires by using the slow motion screws; meanwhile the other telescope was kept properly pointed for taking a photograph. As it was sometimes found that extremely fine movements were required, electrical arrangements were devised, whereby the observer, on simply pressing a button, could accelerate or retard the rate of the clockwork by a minute amount, instead of actually turning the screws by hand. And about the same time the idea arose of making these corrections automatically. This automatic correction is based on the principle that a freely swinging pendulum, which has no work to do, will naturally keep much better time than the clockwork which has to drive a heavy telescope; and if such a pendulum is therefore arranged to send a current every second through certain electro-magnets, apparatus can be devised to detect whether the clockwork is going properly; and to correct it in the right direction, if it is not.

One or more of these three methods, which may be called hand-guiding, electrical control, and automatic electric control, are used in taking all celestial photographs.

The Photographic Image.—The image of a star on the plate should be, theoretically, merely a point; but in practice it is a small patch on the plate which grows in size as the exposure is lengthened, while at the same time it becomes darker in the middle. One reason for this is that light is many-coloured, and when we attempt to focus it by a lens, we only get a very few colours into even approximate focus; the other colours are not brought to focus at all, and form concentric patches of fainter light on the plate, which increase in size with the error of focus. Thus at best our focusing is only a compromise. When the image has a share in the colours which have most nearly been brought to focus have an effect, while the faint light of the others may produce no sensible impression. It is natural to select for the colours to be brought most sharply to focus those which are most important photographically, viz. those at the violet end of the spectrum. As the exposure proceeds the faint light of the other colours affects the plate by accumulation, and hence the image spreads, while at the same time the central part naturally becomes blacker.

A reflecting telescope brings all colours to the same focus; and it might appear, therefore, that images formed with it will not spread in this way. There is, however, another cause of spreading besides that due to colour; neither the reflecting telescope nor the lens can focus all the light received by them for more than one particular star. It is just theoretically possible to construct a mirror which would focus all the light from a star in the direction of its axis; but the light from another star seen in a slightly different direction would not be truly focused, since directly we leave the axis, some parts of the mirror have a focus slightly different from other parts; and if the image...
PHOTOGRAPHY, CELESTIAL

produced is magnified, it is seen to have a shape like that of a kite. As the exposure is prolonged the small kite-shaped figure gradually increases in size from the point towards the broad, and this defect is the more pronounced the farther we depart from the centre of the plate. The result is, speaking generally, that the images near the centre of a plate may be fairly small and circular, but at a certain distance from the centre they become distorted and large. It is a practical problem of great importance to have this distance as great as possible, so that the field of good definition may be large. Estimating in terms of angular distance from the centre of the field, the reflecting telescope has a good field of not more than 4°; a telescope with one compound lens (the ordinary refractor) a field of about 1°, while two compound lenses are used (as is the case in portrait photography) the field may be very greatly extended, 10° or 15° having been successfully covered. This is, naturally, a very great advantage of the "doublet" over other forms of telescope, and the advantage which has only recently been fully realized. But there is a compensating drawback; to get a large field we must either use a large plate, which is liable to bend or to have a permanent curvature; or if we use a small plate the picture will be on a small scale, so that we lose accuracy in another way.

Star Charts may thus be made by photography with any desired combination of these advantages. The Cape Photographische Durchmusterung is a photographic survey of the southern hemisphere by means of 250 plates each covering 5° x 5° taken at the Royal Observatory, Cape of Good Hope; the plates being afterwards measured at Groningen in Holland by Professor J. C. Kapteyn who recorded the places to O1° and O1'. A much higher degree of accuracy is aimed at in the international scheme for a map of the whole sky undertaken jointly by eight observatories in 1887. The plates are only 3° x 2°, and each of the eighteen observatories must take about 600 to cover its zone of the sky once, 1200 to cover it twice. Exposures of 6 min., 3 min., and 20 sec. are given, the telescope being pointed in a slightly different direction for each exposure; so that each star to about the 9th magnitude shows 3 images, and stars to the 12th or 13th magnitude show 2; which has the incidental advantage of distinguishing stars from dust-specks. A network of lines accurately ruled at distances of 5 mm. apart in two directions at right angles is impressed on the plate by artificial light and developed along with the star images; and by use of these reference lines the places of all stars shown with 3 min. exposure are measured with a probable error which, by a resolution of the executive committee, is not to exceed ±0.20". An additional scheme for a series of charts enlarged from similar plates with much longer exposure has proved too costly, and only a few observatories have attempted it. Meanwhile Professor E. C. Pickering of Harvard, by using doublet lenses which cover a much larger field at once, has photographed the whole sky many times over. The plates have not been measured, and would not in any case yield results of quite the same accuracy as those of the international scheme; but being systematically stored at the Harvard Observatory they form an invaluable reference library, from which the history of remarkable objects can be traced back and the wear and tear of the reducing done. Thus the history of the asteroid Pallas, discovered in 1802, was traced back to 1894 from these plates; new stars have been found on plates taken previous to the time of discovery, and the epoch of their blazing up recovered within narrow limits; and the history of many variable stars greatly extended. The value of this collection of photographs will steadily increase with time and growth.

Spectroscopic Star Charts.—By placing a glass prism in front of the object glass of a telescope the light from each star can be extended into a spectrum: and a chart can thus be obtained showing not only the relative positions, but the character of the light of the stars. This method has been used with great effect at Harvard: and from inspection of the plates many discoveries have been made, notably those of several novae.

The Geometry of the Star Chart.—Let OS be the center of the plate on which the photograph is taken, and let its optical center be C. Let PL be the plane, and draw CN perpendicular to the surface of the plate. The point N is of fundamental importance in the geometry of the star chart and it is natural to call it the plate centre; but it must be carefully distinguished from two other points which are occasionally beyond the plate, and others, as practice, coincide with it. The first is the centre of the material plate, as placed in position in the telescope. If we have a figure NL, then the two plates will be drawn larger than PN, and this material centre would be to the right of N. The second point is that where the optics of the plate, and of the glass (CG in the figure) cuts the plate. The object glass is drawn with an exaggerated tilt so that CG falls to the right of N. So when adjustment, the object glass would be "squared on" to the tube by a familiar operation, so that the tube is parallel to CG: and then the plate should be set normal to the tube, and therefore to CG. This is done by observing reflected images, combined with rotation of the plate in its plane.

The plate may be natural or be curved: so that the points of best focus for different stars lie on a surface such as AGB (purposely exaggerated). The best practical results for focus will thus be obtained by compromise, placing the plate so that the stars are as near the edge of the plate, and others, as B, nearer the object glass: exact focus only being possible for a particular ring on the plate. The star A will thus be represented by a small patch of light, p1, on the plate, which will grow in size as the observation proceeds. With this adjustment we can select the centre as best we can; and in practice it is important that the point selected should be that where the line CN drawn from the star to the optical centre cuts the plate. If this can be done, then in the part chart representing the heavy part of the heavy stars we will add that every straight line corresponds to a great circle on the celestial sphere. Hence if we measure any rectilinear co-ordinates (x, y) of a series of stars on one plate, and co-ordinates (X, Y) of the same stars on another plate, and (x, y) are connected by a linear relation, so must (X, Y) be. This property leads at once to the equations:

\[
\begin{align*}
    X &= (ax + by + c)/(1 - kx - ly), \quad (1) \\
    Y &= (dx + ey + f)/(1 - kx - ly), \\
    \text{the numerators being any linear functions of (x, y) but the denominators being a constant.}\end{align*}
\]

If we scale the equation:

\[
X = (x + a)/(1 - kx - ly), \quad (2)
\]

then any straight line, a part of which lies on the plate, projects on a straight line; and in the present instance we may add that every straight line corresponds to a great circle on the celestial sphere. Hence if we measure any rectilinear co-ordinates (x, y) of a series of stars on one plate, and co-ordinates (X, Y) of the same stars on another plate, and (x, y) are connected by a linear relation, so must (X, Y) be. This property leads at once to the equations:

\[
\begin{align*}
    X &= (ax + by + c)/(1 - kx - ly), \quad (1) \\
    Y &= (dx + ey + f)/(1 - kx - ly), \\
    \text{the numerators being any linear functions of (x, y) but the denominators being a constant.}\end{align*}
\]

As a particular case the co-ordinates:

\[
x = \cos \delta \cos \alpha, \quad y = \tan \delta \sin \alpha 
\]

represent the rectangular co-ordinates of a star at RA and declination a and \(\delta\), projected on the tangent plane at the north pole. If the same star be projected on the tangent plane at the point (A, D), then its rectangular co-ordinates (\(X, Y\)) will be:

\[
\begin{align*}
    \xi &= \tan(\alpha - A), \quad (y = \tan(\gamma - D), \quad \text{or the co-ordinates of the origin of (xy) on plate (XY). The co-ordinates of the origin of (XY) on plate (xy) can be shown to be (k, l) if proper units of length be chosen.}
\end{align*}
\]

As a particular case the co-ordinates:

\[
x = \cos \delta \cos \alpha, \quad y = \tan \delta \sin \alpha 
\]

represent the rectangular co-ordinates of a star at RA and declination a and \(\delta\), projected on the tangent plane at the north pole. If the same star be projected on the tangent plane at the point (A, D), then its rectangular co-ordinates (\(X, Y\)) will be:

\[
\begin{align*}
    \xi &= \tan(\alpha - A), \quad (y = \tan(\gamma - D), \quad \text{or the co-ordinates of the origin of (xy) on plate (XY). The co-ordinates of the origin of (XY) on plate (xy) can be shown to be (k, l) if proper units of length be chosen.}
\end{align*}
\]
are well adapted to solution by least squares or any equivalent device.

Photography of Nebulae and Clusters.—Some of the earliest and most striking successes in celestial photography were the pictures of nebulae. Dr A. A. Common (1841-1903), F.R.S., of Ealing, led the way in 1883 with a successful picture of the great nebula in Orion, taken with a 3 ft. concave mirror by Calver. Dr Isaac Roberts (1829-1904) was the first to show the real structure of the great nebula in Andromeda, by a photograph also taken with a reflector. In the clear atmosphere of the Lick Observatory in California, small nebulae were photographed in great numbers by Professor J. E. Keeler (1857-1900); and it was shown what a large percentage were spiral in form. Prof. G. W. Ritchey, at the Yerkes Observatory, has followed up these successes with a 2-ft. reflector, and is constructing a 5-ft., to be erected on Mt Wilson (Cal.); but he has also shown that pictures of clusters are best taken with a telescope of long focus, such as the great Yerkes refractor; and incidentally that this telescope, although intended for visual work, can be adapted to photography by using a "colour screen" just in front of the plate, which sifts out the rays not brought to focus.

Photography of the Moon.—G. W. Ritchey has used the same device of a colour screen for the moon, and obtained even better pictures than those obtained at Paris, which were previously the best. The positions of a large number of craters and other points have been measured by Dr J. H. G. Franz and S. A. Sauder on photographs, and a new epoch in lunar topography has thereby been created.

Photography of the Planets.—Some striking successes have been obtained at the Lowell Observatory, Flagstaff, Arizona: by cutting down the aperture of the object-glass some of the delicate markings, called canals, on the planet Mars have been photographed; but even these do not approach what can be seen by the eye.

Photography of Comets.—Some wonderful pictures have been obtained of comets by Professor E. E. Barnard and others. Here, as in the case of nebulae, the photograph is superior to the eye in detecting faint luminosity, and delicate details of the tail structure have been photographed which could never be seen. In several pictures the tails have an appearance of violent shattering, and if successive pictures can be obtained at such times we may learn something of the nature of such disturbances.

Solar Photography.—The light of the sun is so intense that the chief difficulty is to obtain a short enough exposure. When successfully taken, photographs of the surface show the well-known spots and the mottling of the surface. The image sensibly falls off in intensity towards the limb, owing to the absorption of light by the solar atmosphere; and the bright faculae (which are thus inferred to lie above the main absorbing layer) are seen near the limb. But an immense advance in solar photography was made about a dozen years ago by the invention of the spectroheliograph, which is an instrument for photographing in the light of one very definite colour—say a single hydrogen line. The facuous appearances can be photographed with this instrument all over the sun's disk, instead of merely near the limb. The appearances presented varies enormously with the line selected, or (in the case of the wide "lines" in the spectrum, such as the H and K lines) with the particular part of the same line selected. But for a full account of such matters reference must be made to the articles Sun and Spectroheliograph.

PHOTOMETRY (from Gr. φως, φωτος, light, μέτρον, a measure), the art and science of comparing the intensities or illuminating powers of two or more sources of light. As in all scientific measurements, its methods are attempts to give quantitative accuracy to the crude comparisons made by the eye itself. The necessity for this accuracy in practical affairs of life has arisen because of the great development of artificial lighting in recent times. The eye soon learns to associate with any particular source of light a quality of brightness or power of illumination which diminishes with increase of distance from the source of the eye or from the surface illuminated. This quality depends upon an intrinsic property of the source of light itself, generally known as its "candle power." The aim of photometry is to measure this candle power; and whatever be the experimental means adopted the eye must in all cases be the final judge.

In the photometric comparison of artificial lights, which frequently vary both in size and colour, direct observation of the sources themselves does not yield satisfactory results. It is found to be much better to compare the illuminations produced on dead white surfaces from which no regular reflection takes place, or through colourless translucent material uniformly illuminated by the light placed on the further side. By such processes there is always loss of light, and we must be certain that the light of the given candlepower is reduced in the same proportion. This necessary condition is practically satisfied by the use of white diffusing screens.

Two principles of radiation underlie many photometric applications, namely, the inverse square distance law, and J. H. Lambert's "cosine law." Both can be established on theoretical grounds, certain conditions being fulfilled. But as these conditions are never absolutely satisfied, the applicability of the two laws must in the end be tested by experiment. Since we find that within the errors of observation four candles, placed together at a distance of 2 ft. from a diffusing screen, produce the same illumination as one candle at a distance of 1 ft., we may regard the inverse square distance law as satisfied. Thus if two lights of intensities A and B produce equal illuminations on a screen when their distances from the screen are respectively a and b, we at once draw the relation between the two intensities in the form A : B = a² : b². The theoretical basis of the law follows at once from the universally accepted view that light is energy radiating outwards in all directions from the source. If we assume that there is no loss of energy in the transmitting medium, then the whole amount of radiant energy passing in one second across any closed surface completely surrounding the source of light must be the same whatever the size or form of the surface. Imagine for simplicity a point source of light, or its equivalent, a uniformly radiating spherical surface with the point at its centre, and draw round this point a spherical surface of unit radius. Across this surface there will pass a definite amount of radiant energy, in other words a definite total luminous flux, E, which will be the same for all concentric spherical surfaces. Since the area of a spherical surface of radius r is 4πr², the flux which crosses unit area is E/4πr². This quantity is the "illumination." It is measured in terms of the unit called the lux, which is defined as the illumination produced by a light of unit intensity on a perfectly white surface at a distance of 1 ft. In the great majority of photometers the illuminations are compared, and the intensities are deduced by applying the law of the squared distances.

Lambert's cosine law has to do with the way in which a luminous surface sends off its radiations in various directions. It is a matter of common observation that the disk of the sun appears equally bright all over the surface. Careful measurements show that this is not strictly true; but it is sufficiently near the truth to suggest that under certain definable conditions the law would hold accurately. Again, when a glowing surface is viewed through a small hole in an opaque plate, the brightness is very approximately independent of the angular position of the incandescent surface. This is the same phenomenon as the first mentioned, and shows that the more oblique, and therefore larger, element of surface sends the same amount of radiation through the hole. Hence the amount per unit surface sent off...
PHOTOMETRY

at a given angle with the normal must be less than that sent off in the direction of the normal in the inverse ratio of the areas of the corresponding normal and oblique elements; that is, as the cosine of the given angle to unity. For most practical purposes, and so long as the obliquity is not great, Lambert's law may be assumed to hold.

In almost all accurate methods of photometry the aim is to bring the illuminating powers of the two sources to equality. This may be effected by altering the distance of either light from the illuminated surface. Or we may use polarized light and diminish the intensity of the stronger beam by suitable rotation of a Nicol prism, a method particularly useful in spectrophotometers. The same result may also be effected by interposing absorbing disks, the precise absorbing powers of which must, however, be known with great accuracy. Another useful method is that first described by H. Fox Talbot in 1834, and used with effect by Professor William Swan (1849), and more recently by Sir W. de W. Abney. Talbot's law is thus enunciated by H. von Helmholtz: "When any part of the retina is excited by regularly periodic intermittent light, and when the period is sufficiently short, the resulting impression will be continuous, and will be the same as that which would be produced if the whole light were distributed uniformly throughout the whole period." Talbot deduced the principle from the well-known experiment in which a continuous luminous line is produced by rapid rotation of a luminous point. If the principle be granted, it is obvious that any mechanism by which a ray of light is obstructed in a regularly rhythmic manner during definite intervals of time, separated by intervals of duration, during which the light is allowed to pass, will have the effect of reducing the apparent brightness of the ray in the ratio of the light's duration to its total duration in time.

If photometric results are to be of general value it is essential to have a unit in which to express all other intensities. For example, electric lights are classified according to their "candle-power." The candle, in terms of whose brightness the brightness of other sources of light is to be expressed, must, of course, fulfil the conditions demanded of all standards. It must give under definite and easily realizable conditions a definite and constant luminous effect, and it must be easily reproducible. The earlier attempts to get a candle of constant brightness were not very satisfactory. The British standard is a sperm candle which weighs 1 lb. and loses 120 grams per hour. It is found that these conditions are not sufficient to determine the luminous power of the candle, since the length and shape of the wick, the height of the flame, and the composition, temperature and humidity of the atmosphere all have an effect upon its brightness. The same is true of other similar sources of light—for example, the German standard candle, which is made of paraffin, has a diameter of 0.2 cm., and its wick is 4 cm. high, but which with all precautions suffers continual alterations in brightness. For ordinary practical purposes, however, these candles are steady enough. Other kinds of flame have also been used as a standard source of light. The oldest of these is the French Carcel lamp, which is provided with a cylindrical Argand burner, and gives the standard brightness when 42 grammes of colza oil are consumed per hour. The supply and draught are regulated by clockwork. A. G. Vernon-Harcourt's pentane standard, in which a mixture of gaseous pentane and air is burnt so as to maintain a flame 2.5 in. high at ordinary barometric pressure, gives good results, and is readily adjustable to suit varied conditions. Several forms of this standard have been constructed, one of the most important being the 10-candle-power pentane lamp, in which air saturated with pentane vapour is burnt in a specially-designed burner resembling an Argand burner. For photometric purposes a definite length of the lower part of the flame is used, the upper part being hidden within an opaque tube. The amyl-acetate lamp designed by H. von Heer-Altenbeck has been elaborately studied by the German authorities, and at present is probably more used than any other flame for photometry. It is of simple construction, and gives the standard brightness when it burns with a flame 4 cms. in height in still air of humidity 0.88% and free of carbon dioxide. The presence of carbon dioxide and increase in the humidity have a marked effect in diminishing the brilliancy of the flame. If the vapour pressure is e and the barometric pressure p, the strength of the flame, when all other conditions are fulfilled, is given by the formula

\[ 1.049 - 5.5e/(p - e) \]

One disadvantage for photometric purposes is the reddish colour of the flame as compared with the whiter artificial lights in general use.

For an interesting account of the various experimental investigations into the properties of the Heffner flame see E. L. Nichols, "Standards of Light," Transactions of the International Electrical Congress, vol. ii. (St. Louis, 1904). Angstrom's determination of the radiation of the flame in absolute energy units is also of special interest.

Attempts have been made, but hitherto with limited success, to construct a convenient standard with acetylene flame. Could a satisfactory burner be devised, so that a steady brilliancy could be easily maintained, acetylene would, because of its intense white light, soon displace all other flames as standards.

J. Viole has proposed to use as standard the light emitted by a square centimetre of surface of platinum at its melting point, but there are obvious practical difficulties in the way of realizing this suggested standard. J. E. Viole's Platinum Standard.

Fleming's Incandescent Lamp Standard.
photometer. The earlier forms of photometers were very simple and not capable of giving very precise results. The principles of construction are, however, the same in all the recognized forms down to the most elaborate of recent inventions. Two of the earliest forms were described by P. Bouguer and W. Ritchie. The Ritchie wedge constitutes the basis of many varieties of type. The two lights to be compared illuminate the sides of the wedge, which is placed between them, so that the eye set in front of the wedge sees the two sides illuminated each by one of the lights. The edge should be as sharp as possible so that the two illuminated surfaces are in close contact. The illuminations are made equal either by shifting the wedge along the line joining the lights or by moving one of the lights nearer to or farther from the wedge as may be required. The lights given out by the sources are then as the squares of the distances from the matched parts of the surfaces. Count Rumford suggested the comparison of the intensity of light from the shadows of the same object thrown side by side on a screen by the two lights to be compared. In this case the shadow due to one source is lit up by the other alone; and here again the amounts of light given out by the sources are as the squares of their distances from the screen when the shadows are equally intense. The shadow-casting object should be near the screen, so as to avoid penumbra as much as possible; yet not too near, so that the shadows may not overlap.

R. Bunsen suggested the very simple expedient of making a grease-spot on white paper for photometric purposes. When the paper is equally illuminated from both sides the grease-spot cannot be seen except by very close inspection. In using this photometer, the sources are placed in one line with the grease-spot, which lies between them and can be moved forward and backward to make the most accurate determinations with this arrangement the adjustment should first be made from the side on which one source lies, then the screen turned round and the adjustment made from the side of the other source—in both cases, therefore, from the same side of the paper screen. Take the mean of these positions (which are usually very close together), and the amounts of light are as the squares of the distances of the sources from this point. The efficiency of the Bunsen photometer has been improved by using two inclined mirrors so that the eye views both sides of the paper simultaneously.

Sir Charles Wheatstone suggested a hollow glass bead, silvered internally, and made to describe very rapidly a closed path, for use as a photometer. When it is placed between two points of light in the same way as the Bunsen's photometer, the light given out from the point of light is increased in proportion to the amount of silver so that the two lights are of equal intensity. The method is made more sensitive by mounting the photometer on an elastic bar so as to render it capable of slight to-and-fro oscillation about a mean position. A network of wires can be adapted for measuring the illumination in a region that is due to L. Weber. It consists of a horizontal tube across one end of which is fitted another tube at right angles. This second tube can be rotated so that the beam of light is directed in any position desired. Where the axes of the two tubes meet is placed in the later forms of the instrument one of Lummer and Brodhun's modified Swan cubes. At the other end of the horizontal tube a standard flame is set illuminating a piece of ground glass which may be moved to any convenient position in the tube. The eye looks along the cross tube, at the farther end of which is placed another piece of ground glass illuminated from the outside. The illuminations of the two pieces of ground glass are brought to equality, either by shift of the ground glass to or from the standard light, or by means of two Nicol prisms placed in the cross tube. One advantage of the instrument is its portability.

The photometry of incandescent electric lamps has led to several special modifications and devices. The candle power varies distinctly in different horizontal directions, and, in particular, in the equator. The lamp is not sufficient. Sometimes the lamp is rotated about three times a second about a vertical axis and an average value thus obtained. But there is always a risk of the filament breaking; and in all cases the effect of centrifugal force must alter the form of the filament and therefore the distances of the different parts from the screen. Accuracy demands either the measurement of the radiation intensity in a number of directions all round the lamp, or one combined...
PHOTOMETRY

measurement of as many rays as can be conveniently combined. One of the best methods of effecting this is by means of Matthews's C. P. Matthews's integrating photometer. By the integrating use of twelve mirrors arranged in a semicircle whose diameter coincides with the axis of the lamp, twelve rays are caught and reflected outward to a second set of twelve mirrors which throw the rays on to the surface of a photometric screen. This combined effect is balanced by the illumination produced by a standard lamp on the other side of the screen (see Trans. Amer. Inst. Elect. Eng., 1902, vol. xix.).

So long as the lights to be compared are of the same or nearly the same tint, the photometric match obtained by different observers is practically the same. If, however, they are of distinctly different colours, not only do different observers obtain different results but those obtained by the same observer at different times are not always in agreement. Helmholtz was of opinion that photometric comparison of the intensities of different coloured lights possessed no real intrinsic value. There can be little doubt that in a rigorous sense this is true. Nevertheless it is possible to obtain certain conditions to effect a comparison which has some practical value. For example, when the intensities of two differently coloured lights differ considerably there is no difficulty in judging which is the stronger. By making the one light pass through a fairly large range of brightness we may easily assign limits outside which the intensities are undoubtedly different. After some experience these limits get close; and many experimenters find it possible, by taking proper precautions, not only to effect a match, but to effect practically the same match time after time. According to Abney, whose memoirs on colour photometry (Phil. Trans., 1886, 1889) form a most important contribution to the subject, the observer in making his judgment as to the equality of luminosity of two patches of colour placed side by side must not begin to think about it, but must let the eye act as unconsciously as possible. His method was to compare the coloured patch with white light given by a particular standard and cut down to the proper intensity by use of a Talbot's rotating sector, which could be adjusted by means of a suitable mechanism while it was rotating.

At the same time, although the eye may be able to effect a definite matching of two patches of colour of a particular luminosity, it has been long known that a change in the luminosity will destroy the apparent equality. This depends upon a physiological property of the retina discovered by J. E. Purkinje in 1825 (see below, Celestial Photometry). In virtue of this property the blue and violet end of the spectrum is more stimulating to the eye than the red end when the general luminosity is low, whereas at high luminosities the red gains relatively in brightness until it becomes more stimulating than the blue. Unless therefore account is taken in some definite measurable manner of the absolute brightness, there must always be some uncertainty in the photometric comparison of the intensities of differently coloured sources of light. Instead, however, of trying to effect a photometric match in one of the ways which have been found sufficient when the sources are of the same or nearly the same tint, we may effect important practical comparisons in what is called heterochromatic photometry by an appeal to other physiological properties of the eye. For example, the power of clearly discriminating patterns in differently coloured lights of various intensities is obviously of great practical importance; and this power of detailed discrimination may be made the basis of a method of photometry. According to this method two lights Discrimina- are arranged so as to illuminate two exactly similar Photo-patterns of lines drawn, for example, on the sides of a Ritchie wedge, and their distances are adjusted until the patterns are seen equally distinct on the two sides. Application of the usual distance law will give the relation between the two lights. A discrimination photometer constructed on this principle has been designed by J. A. Fleming. Its results do not agree with the indications of an ordinary luminosity photometer; for it is found that the eye can discriminate detail better with yellow than with blue light of the same apparent luminous intensity.

Another and very promising method of photometry depends upon the duration of luminous impressions on the retina. J. A. F. Plateau observed in 1829 that the blending into Flicker a homogeneous impression of a pattern of alternate Photometry, sectors of black and some other colour marked on a disk when that disk was rotated occurred for rates of rotation which depended on the colour used. A form of experiment suggested in Professor O. N. Rood's Modern Chromatics seems to have been first carried out by E. L. Nichols (Amer. Journ. of Science, 1881). A black disk with four narrow open sectors was rotated in front of the slit of a spectroscope. When the rotation was not too quick the yellow part of the spectrum appeared as a succession of flashes of light separated by intervals of darkness of appreciable length, whereas towards both the red and violet ends no apparent interruption in the steady luminosity could be observed. As the rate of rotation increased the pattern of the spectrum in which flickering appeared contracted to a smaller length extending on each side of the yellow sector. Finally with sufficiently rapid alternation the yellow itself became steady. This seems to show that the retinal image persists for a shorter time with yellow light than with light of any other colour; for with it the intervals of darkness must be shorter before a continuous impression can be obtained. Now yellow is the most luminous part of the spectrum as it affects the normal human eye; and E. S. Ferry (Amer. Journ. of Science, 1892) has shown that the duration of luminous impression is mostly, if not entirely, determined by the luminosity of the ray. Hence the determination of the minimum rate of intermittence at which a particular colour of light becomes continuous may be regarded as a measure of the luminosity, the slower rate corresponding to the lower luminosity. Although in the experiment just described the red part of the ordinary solar spectrum becomes continuous for a slower rate of intermittence than the yellow part, yet we have simply to make a red ray as luminous as the yellow ray to ensure that they become continuous for the same rate of intermittence. It is, however, highly improbable that the duration of impression depends only on the luminosity of the light and not to some extent upon the wave-length. There are indeed phenomena which require for their explanation the assumption that the duration of luminous impression does depend on the colour as well as on the brightness.

Nevertheless the luminosity is by far the more important factor, as shown by Ogden N. Rood's experiments. He found (Amer. Journ. of Science, 1893) that, when a disk whose halves differ in tint but not in luminosity is rotated rather slowly, the eye of the observer sees no flickering such as is at once apparent when the halves differ slightly in luminosity. Rood himself suggested various forms of photometer based on this principle. In his latest form (Amer. Journ. of Science, Sept. 1899) the differently coloured beams of light which are to be compared photometrically are made to illuminate the two sides of a Ritchie wedge set facing the eye. Between the wedge and the eye is placed a cylindrical concave lens, which can be set in oscillation by means of a motor in such a way that first the one illuminated surface of the wedge and then the other is presented to the eye in sufficiently rapid alternation. The one source of light is kept fixed, while the other is moved about until the sensation of flicker disappears. From work with this form of instrument Rood concluded that 'the accuracy attainable with the flicker photometer, as at present constructed, and using light of different colours almost spectral in hue, is about the same as with ordinary photometers using plain white light, or light of exactly the same colour.'

Various modifications of Rood's forms have been constructed from time to time by different experimenters. The Simmance and Abady flicker photometer is an ingenious and mechanically simple method by which (as the photometer, were) the wedge itself is made to oscillate so as to throw on the eye in rapid succession, first the one side and then the other. The rim of a wheel of white material is bevelled
in a peculiar manner. The sharp edge, which passes slightly obliquely across the rim from one side of the wheel to the other and back again, is the meeting of two exactly similar conical surfaces facing different ways and having their axes parallel to, but on opposite sides of, the axis of rotation of the wheel. Of this, the observer with its rim facing the eye, the intersection of the two surfaces, crosses and recrosses the line of vision during each revolution. Hence first the one illuminated side and then the other are presented to the eye in rapid alternation, and in terms of the angle of rotation of the Nicol the relative intensities of the original rays can be calculated. An important application of the spectrophotometer is to measure the absorbive powers and extinction coefficients of a substance for the differently coloured rays of light. By appropriate means the intensities of chosen corresponding parts of the two contiguous spectra are made equal—in other words, a match is established.

To facilitate experiments of this kind Dr. J. R. Milne has devised a spectrophotometer which presents some novelties of construction (see Proceedings of the Optical Convention, 1905, vol. i). The light from a brilliant flame is suitably divided by a lens into illuminated areas, one half facing the slit end of the collimator. The rays from the source are made parallel by the collimator, and then pass, partly through the absorbing medium, partly through the space above it. These two parts of the original beam are transmitted through a dispersing instrument and then focused by a second lens into parallel openings, the upper one allowing the unab sorbed part of the beam to pass, the lower part which has been transmitted through the absorbing medium. The objective of the observing telescope is then engaged with this beam of varying intensity as it passes through the two spectra seen side by side, having their light polarized in perpendicular planes. A Nicol prism is placed between the Wollaston prism and the eye-piece of the telescope, and by its rotation in the plane of the spectroscope the two spectra are brought side by side, with the corresponding prices of the two spectra can be brought to equality. By careful attention to all necessary details Milne shows that his instrument satisfies the requirements of a good spectrophotometer: (1) the plane of the Nicol, parallel to that of the prism, can be so adjusted that (2) the two spectra can be brought with ease accurately edge to edge without any diffraction effects; (3) the plane of the delimiting screen can be made conjugate to the retina of the observer's eye; (4) the two prisms can be made to project accurately along their common edge, but the two fans of rays which proceed from every point of the common edge lie in one and the same plane; (5) the eye is called upon to judge the relative intensities not of two narrow slits but of two equally illuminated areas. Milne also points out that this instrument can be used as a spectropolarimeter.

E. L. Nichols considers that spectrophotometers which depend for their action upon the properties of polarized light are necessarily open to serious objections, such as: selective absorption in the calcspar, altering the relative intensities of the constituents in the original rays; selective losses by reflection of polarized rays at the various optical surfaces; and the necessarily imperfect performance of all forms of polarizing media. To eliminate these defects as far as possible great care in construction and arrangement is needed, otherwise corrections may be applied.

It is evident that if the successive parts of two spectra are compared photometrically we may by a process of summation obtain a comparison of the total luminosities of the lights which form the spectra. This process is far too tedious to be of any practical value, but sufficiently accurate results may in certain cases be obtained by comparison of two or more particular parts of the spectra, for example, strips in the red, green and blue. Similar in principle is the method suggested by J. Macé de Lapinay, who matches his lights by looking first through a red glass of a particular tint and then through a chosen green. If R and G represent the corresponding ratios of the intensities, the required comparison is calculated from the formula

$$I = \frac{R}{1 + 0.208(1 - GR)}$$

A. Crova, one of the earliest workers in this subject, effects the photometric comparison of differently coloured lights by matching those monochromatic rays from the two sources which have the same ratio of intensities as the whole collected rays that make up the light. Careful experiment alone can determine this particular ray, but were it once ascertained for the various sources of light in use the method would have the merits of rapidity and accuracy sufficient for...
PHOTOMETRY

530

Sir John, in the very midst of establishing his "sequences," adopting also an instrumental method which might lead him to more definite results.

In the year when Sir John Herschel concluded his photometric work at the Cape (1838) Dr. F. W. A. Argelander commenced, and in 1843 completed, his Uranometria nova, in which the magnitudes of all stars visible to the unaided eye in central Europe are catalogued with a precision and completeness previously unknown. It contains 3256 stars, and although it will probably be superseded by instrumental photometry it must ever remain a monument of intelligent patience. Argelander's labours were not confined to stars visible to the naked eye; by the aid of his assistants, Dr. E. Schönfeld and Dr. A. Krüger, three catalogues of magnitudes and celestial co-ordinates were ultimately published (1859-1863) as the Bonn Durchmusterung, including the enormous number of 334,188 stars, and an additional volume containing 133,659 stars south of the equator was published in 1886.

Dr. B. A. Gould (1824-1896), in his Uranometria argentina (1879), has done similar work for 7756 stars visible only in the southern hemisphere, and his successor at Córdoba, J. M. Thome, has published (1904) three volumes of the Argentine (Córdoba) Durchmusterung containing 48,662 stars between declination −25° to −52°. There have been other worthy labourers in the same field, each of whom has rendered efficient service, such as Dr. E. Heis and M. J. C. Houzeau.

It is to Sir John Herschel that we are indebted for the first successful attempt at stellar photometry by what may be termed "artificial" means. He deflected the light of the moon (by means of the internal reflection of a rectangular prism) through a small lens 0.12 in. in diameter and of very short focus (0.23 in.) so as to form a sort of artificial star in its focus. With strings and a wooden pole he could move this artificial star of comparison so as to be in the same line of sight with any actual star whose light he proposed to measure. Other strings enabled him to remove it to such a distance from the eye that its light was adjudged to be sensibly the same as that of the star compared; and the distance was measured by a graduated tape. While he was thus busy at the Cape of Good Hope, K. A. Steinheil at Munich had completed for Dr. P. L. Seidel an instrument nearly the same in principle but more manageable in form. He divided the small object-glass of a telescope into two halves, one of which was movable in the direction of its axis. The images of two stars whose light he desired to compare were formed by prismatic reflection, nearly in the same line of sight, and one of the lenses was then moved until the light of the two images seemed to coincide. The distance through which it was necessary to bring the movable lens furnished the data for comparing the relative lustre of the two stars in question. More recently other photometers have been devised, and descriptions of three of them, with which considerable researches have been conducted will now be given. With the first mentioned below Professor Pickering of Harvard has made more than a million measures with his own eyes. The results of his observations, and of those of his assistants, will be found in the Harvard Annals especially in vol. xiv. published in 1901, which contains a general catalogue of about 24,000 stars brighter than magnitude 7.5, north of declination −40°. With the Zöllner photometer Drs. Gustav Müller and P. Kempf of Potsdam have recently completed a similar piece of work, their catalogue of stars north of the equator brighter than 7.5 containing 14,199 stars (Potsdam Publications, 1907, vol. xvii.). The catalogue of Professor C. Pritchard was smaller, containing 2784 stars brighter than magnitude 6.5 and north of declination −10°; but it was published in 1886, when very little had yet been done towards the systematic measurement of the brightness of the stars (Uranometria nova oxoniensis, vol. ii. of the Oxford University Observatory publications).

Pickering's meridian photometer (Ann. Astron. Obs. Harvard, vols. xiv. and xxiii.) consists of two telescopes placed side by side pointing due east, the light from the stars on the meridian being reflected into the objects eyes by mirrors inclined at an angle of 45° to this direction. If there were a star exactly at the Pole, one of these mirrors...
would be absolutely fixed and would constantly reflect the light of this star down the axis of its telescope; in practice a slight motion can be given to the mirror so as to keep in view the polar star selected, whether Polaris, with which the Nicol prism interfered, or any other.

Pickering's Photometer.

Minoris, which was used for fainter stars. The second mirror (which projects a little beyond the first so as to get an unobstructed view of the meridian) can be rotated round the axis of the refracting telescope, and so arranged that the Nicol prism can thus be made to reflect any star on the meridian down the second telescope; it is also provided with a small motion in the perpendicular direction, so as to command a degree or two on each side of the meridian. Near the common eyepiece of the apparatus there is a double image prism which separates the light received from each into two pencils; the pencil of ordinary rays from one object-glass is made to coincide with that of extraordinary rays from the other, and the two remaining pencils are excluded by a screw device, so that two stars are presented to the eye of the observer, who by rotating the prism round its axis can equalize them at a definite reading depending on their relative intensities. This reading gives in fact the difference of magnitude between the two stars as measured under the conditions of the Nicol image. It was remarked that the position of the double image prism is important. It should be just within the focus; the common focus: this position prevents any noticeable colour in the images, and gives the ordinary and extraordinary pencils the same opportunity to impinge on the eye-stop to permit the entire exclusion of one without the loss of any part of the other. If the prism were exactly at the focus, and any part of the superfluous images were admitted, the resulting secondary images would be considerably diminished, and hence errors in observing. But in the actual construction of the instrument the secondary images would appear, if at all, only as additional stars near those under observation, and too faint to produce any appreciable error. It may be added that Mr. Pickering has extended his survey into the southern hemisphere, so that the Harvard photometry is the most complete of all. Each observation consists of four comparisons; after the first two the observer notes the position of the Nicol image, and then adjusts the eyepieces to equalize the brightness of the two stars, which also reverses the double-image prism. The former precaution is necessary in order to eliminate a curious error depending on the relative position of the images, which may amount to several tens of a magnitude. Energy of this kind might persist to equalize the brightness of two stars in the same field, as has been repeatedly shown; a striking instance is given by A. W. Roberts, of Lovedale, South Africa (Mon. Not. R. A. S. April 1897), who found that his eye-estimations of the brightness of variable stars required a considerable amount of time to reach a uniform reading in the double-image prism, even though the phase of the comparison stars varied over nearly two magnitudes.

In Zöllner's instrument an artificial star is taken as the standard of comparison. There is only one telescope, and inside the tube of the eyepiece is a wedge of quartz containing two specially prepared Nicols. This instrument enters the tube from the side are reflected down the tube through the Nicols and prism to the eyepiece, while the light from the star passes through the tube and Nicols and prism to the eyepiece. Each Nicol is a Nicol prism and a plate of rock crystal, which give control over the glass; through two Nicols which can be rotated round the axis of the beam to definite positions read off on a graduated circle; and the Nicols are held between two high-quality lenses and a glass plate to focus the enlarged image. The whole of this apparatus is carried in a compact form on the eye end of the telescope, being arranged that the light shall always stand upright. The scepticism of the artificial star is equal to that of the star viewed through the object-glass, and reading the graduated circle.

Professor Pritchard's (1860-1893) wedge photometer is constructed on the principle of the Zöllner's, but through a uniform medium depends, caeteris paribus.

The Wedge. Photometer. upon the thickness. On this principle a thin wedge of homogeneous and nearly neutral-tinted glass is constructed of different thicknesses, so that the different points of a telescope are viewed. Simple means are contrived for measuring with great exactness the several thicknesses at which the light of these telescopc images is extinguished. In this way the light in the image of any star can be repeatedly compared with that of Polaris, or any other selected star) at the moment of observation, and thus a catalogue of star-magnitudes can be formed.

Two material improvements suggested by Dr. E. J. Spitta are worthy of notice. The first (Proc. Roy. Soc., 1887, p. 15) is the insertion of a silver deposit on the wedge itself. If a pair of rays passes through a thin wedge of tinted glass, the rays do not pass all through the same thickness of glass. Dr. Spitta proposes to substitute a pair of wedges with their thicknesses increasing in opposite directions, so that whenever one ray is stopped on a centrally placed plate of glass of varying thickness, and a uniform beam of light of sensible dimensions can then be extinguished satisfactorily. He has also pointed out a source of error in the method of finding the wedge and shown how to correct it. The value was determined by Professor Pritchard by the use of a doubly refracting prism of quartz and a Nicol prism. Using this method subsequently, Dr Spitta found that internal reflections within the Nicol prism interfered with the accuracy of the result, but that this error could be eliminated by using a suitable diaphragm (Mon. Not. R. A. S. March 1890; Abney, ibid., June 1890).

Since 1855 systematic catalogues of stellar brightness have been constructed with all these instruments, and it has been of great interest to compare the results. The comparison has in general shown a satisfactory agreement, but there are small differences which are almost certainly systematic, due to the difference of method and instrument. One cause of such differences, the reality of which is undoubted, but the effects of which have as yet not been perhaps fully worked out, is the " Purkinje phenomenon" (Pflügers Archiv. lxx. 297). If a blue source of light and a red source appear equally bright to the eye, and if the intensity of each be diminished in the same ratio, they will no longer appear equally bright, the blue now appearing the brighter; in more general terms, the equalizing of two differently coloured lights by the eye depends upon their intensity. It is clear that this phenomenon must affect all photometric work unless the stars are all exactly of the same colour, which we know they are not. For let us suppose that both the comparison star of the meridian photometer and the artificial star of the wedge photometer are a bright star A, and that they could be also compared inter se and found equally bright. Then when a faint star B comes under observation and the intensities of the comparison stars are both reduced to equality with B, they will no longer appear equal to one another unless they are exactly the same in colour. In other words, the observed ratio of intensities of A and B will vary with the colour of the comparison star, and similarly it will also vary with the aperture of the telescope employed. Now it is one of the merits of the Potsdam catalogue above mentioned that it gives estimates of the colours of the stars as well as of their magnitudes — so that we now for the first time have this systematic information. In a most interesting section of their introduction it is shown that two of the Harvard photometric catalogues show systematic differences, due to colour, and amounting to nearly half a magnitude: and that the Purkinje phenomenon is a satisfactory explanation of these differences. This is the first instance in which the effect of this phenomenon has been measured in the case of the stars, and the author was known to be sensible. But there is a set of numerical results obtained in the laboratory which is of importance for all such works, viz. those obtained by Sir W. Abney (Proc. Roy. Soc. May 1891; and Mon. Not. R. A. S. April 1892), giving the limiting intensity at which each pure colour vanishes. If we start with lights C D E F G of the colours usually denoted by these letters in the spectrum, and each so bright that it appears to the eye as bright as an amylacetate lamp at 1 ft., and if then the intensity of each be gradually diminished, the C light will disappear when the original intensity has been reduced to 22,000 ten-millionths of the original value. The other colours will disappear at the following intensities, all expressed in ten-millionths of the original: D at 350, E at 35, F at 17, and G at 15. If then we had a mixture of two lights, one of C colour as bright as before, and the other of G colour 1000 times fainter (a combination in which the eye would be unable to distinguish the G light at all), and if with an intensity reduced to one millionth of the original, the C light would diminish so much more rapidly than that of the G that the latter would begin to assert itself, and when the combined intensities were reduced to 22,000 ten-millionths of the original value, the C light would have all disappeared, while the G light would not. Hence the colour of the light would appear pure violet, though it was originally deep red. This extreme case shows that the "last ray to disappear" when a light is gradually extinguished may be very different in colour from that of the original light, and when more usual light-mixtures are considered, such as those of sunlight and starlight, which appear nearly white to the eye, the "last ray to disappear" is found to be in the green, very near E in the spectrum. This result has two important bearings on the use of the wedge photometer. In the first place,
PHOTOMETRY

either the wedge itself should be of a greenish hue, or green light should be used in finding the scale-value (the constant B in the formula $m = A + B \omega$). In the second, star magnitudes obtained by extinction with the wedge will agree better with those obtained by photography than those obtained with other visual photometers, since photographic action is chiefly produced by rays from E to G in the spectrum, and the E light of ultimate importance with the wedge photometer is nearer this light in character than the D light with which other photometers are chiefly concerned. It would also appear that results obtained with the wedge photometer are independent of the aperture of telescope employed, which is not the case with other photometers.

Passing now to the consideration of photographic methods, it is found that when a plate is exposed to the stars, the images of the brighter stars are larger and blacker than those of the fainter ones, and as the exposure is prolonged the increase in size and blackness continues. Much of the light is brought to an accurate focus, but, owing to the impossibility of perfect achromatism in the case of refractors, and to uncorrected aberration, diffraction, and possibly a slight diffusion in both refractors and reflectors, there are rays which do not come to accurate focus, grouped in rings of intensity gradually diminishing outwards from the focus. As the brightness of the star increases, or as the time of exposure is prolonged, outer and fainter rings make their impression on the plate, while the impression on the inner rings becomes deeper. Hence the increase in both diameter and blackness of the star disks. As these increase concurrently, we can estimate the magnitude of the star by noting either the increase in diameter or in blackness, or in both. There is consequently a variety in the methods proposed for determining star magnitudes by photography. But before considering these different methods, there is one point affecting them all which is of fundamental importance. In photography a new variable comes into play, that is the time of exposure, viz., the time of exposure, and it is necessary to consider how to make due allowance for it. There is a simple law which is true in the case of bright lights and rapid plates, that by doubling the exposure the same photographic effect is produced as by increasing the intensity of a source of light twofold, and so far as this law holds it gives us a simple method of comparing magnitudes. Unfortunately this law breaks down for faint lights. Sir W. Abney, who had been a vigorous advocate for the complete accuracy of this law up till 1893, in that year read a paper to the Royal Society on the failure of the law, finding that it fails when exposures to an amyl-acetate lamp at 1 ft. are reduced to $0^\circ$ of $0^\circ$ and "signally fails" for feeble intensities of light; indeed, it seems possible that there is a limiting intensity beyond which no length of exposure would produce any sensible effect. This was bad news for astronomers who have to deal with faint lights, for a simple law of this kind would have been of great value in the complex department of photometry. But it seems possible that a certain modification or equivalent of the law may be used in practice. Professor H. H. Turner found that for plates taken at Greenwich, when the time of exposure is prolonged in the ratio of five star magnitudes the photographic gain is four magnitudes (Mon. Not. R.A.S. lxv. 1775), and a closely similar result has been obtained by Dr Schwarzschild using the method presently to be mentioned.

Stars of different magnitudes impress on the plate images differing both in size and blackness. To determine the magnitude of the exposure, Turner as the cube, Pritchard as the fourth power, while W. H. M. Christie has found the law that the diameter varies as the square of the logarithm of the exposure within certain limits. There is clearly no universal law—it varies with the instrument and the plate—but for a given instrument and plate an empirical law may be deduced. Or, without deducing any law at all, a series of images may be produced of stars of known brightness and known exposures, and, using this as a scale of reference, the magnitudes of other images may be inferred by interpolation. A most important piece of systematic work has been carried out by the measurement of diameters in the Cape Photographic Durchmusterung (Ann. Cape Obsr. vols. iii., iv. and v.) of stars to the tenth magnitude in the southern hemisphere. The measurements were made by Professor J. C. Kapteyn of Groningen, on photographs taken at the Cape of Good Hope Observatory; he adopts as his purely empirical formula

$$\text{magnitudes} = \frac{B}{\text{diameter} + C},$$

where B and C are obtained independently for every plate, from comparison with visual magnitudes. C varies from 10 to 28, and B from 90 to 250. The part of the sky photographed was found to have an important bearing on the value of these constants, and it was in the course of this work that Kapteyn found a systematic difference between stars near the Milky Way and those far from it, which may be briefly expressed in the law, the stars of the Milky Way are in general bluer than the stars in other regions of the sky. It is intended, however, in the present article to discuss methods rather than results, and we cannot here further notice this most interesting discovery.

Of methods which choose the blackness of the image rather than the diameter for measurement, the most interesting is that initiated independently by Pickering at Harvard and C. Schwarzschild at Vienna, which consists in taking star images considerably out of focus. The result is that these images no longer vary appreciably in size, but only in blackness or density; and that the gradation of density is recognizable through a wide range of magnitudes. On a plate taken in good focus in the ordinary way there is a gradation of the same kind for the faintest stars; the smallest images are all of approximately the same size, but vary in tone from grey to black. But once the image becomes black it increases in size, and the change in density is not easy to follow. The images-out-of-focus method seems very promising, to judge by the published results of Dr Schwarzschild, who used a prepared comparison scale of densities, and interpolated for any given star from it. The most satisfactory photographic method would certainly be to take account of both size and blackness, i.e. to measure the total deposit in the film; as, for instance, by interposing the whole image in a given beam of light, and measuring the diminution of the beam caused by the obstruction. But no considerable piece of work has as yet been attempted on these lines.

Even in a rapid sketch of so extensive a subject some notice must be taken of the application of photometry to the determination of the relative amount of light received on the earth from the sun, the moon and the planets. The methods by which these ratios have been obtained are as simple as they are ingenious; and for them we are mainly indebted to the labours of P. Bouguer and W. C. Bond (1789-1859). The former compared the light received from the sun with that from the moon in the following fashion in 1725. A hole one-twelfth of a Paris inch was made in the shutter of a darkened room; close to it was placed a concave lens, and in this way an image of the sun 9 in. in diameter was received on a screen. Bouguer found that this light was equal to that of a candle viewed at 16 in. from his eye. A similar experiment was repeated with the light of the full moon. The image now formed was only two-thirds of an inch in diameter, and he found that the light of this image was comparable with that of the same candle viewed at a distance of 50 ft. From these data and a very simple calculation it followed that the light of the sun was about 256,889 times that
of the moon. Other experiments followed, and the average of all the results was that the light of the sun was about 300,000 times the average light of a full moon, both being viewed in the heavens at the same altitudes. The details will be found in Bouguer’s Traité d’optique. W. H. Wollaston in 1829 tried a series of experiments in which the ratio 801,072 was obtained; but the omission of certain necessary precautions vitiated the result (Phil. Trans. 1829). Bond (Mem. Amer. Acad. 1861, p. 295) adopted a different process. He formed the image of the sun on a silvered globe of some 10 in. diameter; the light of this image was reflected on to a small mercurial thermometer bulb; and then this second image was compared with a Bengal light so moved that the lights appeared to be equal. The same process was adopted with the full moon instead of with the sun. The result was that the sun’s light was 470,980 times that of the moon. Seidel long before this date had compared the light of the mean full moon with that of Jupiter in mean opposition; his result is 6430. So also this light of Jupiter was found to be 4864 times that of Venus at her brightest; and Jupiter was found to give 8.2 times the light of a Lyrae. If, then, these numbers could be accepted with confidence, we should have the means of comparing the light received from the sun with that received from any of the stars. Adopting these precarious numbers on the authorities of Bond and Seidel we have the following results:—

<table>
<thead>
<tr>
<th>Star</th>
<th>Light Relative to Sun</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sun</td>
<td>470,980</td>

<tr>
<td>Sirius</td>
<td>5,970,500,000</td>
</tr>
</tbody>
</table>

Lastly, Bouguer, by comparing the light of the full moon viewed at different altitudes with an artificial light, found that the atmosphere absorbs 1879 of the light incident on it at the zenith of any place. Professor Pritchard, from photometric measures taken at Cairo, found this number to be 1877. At Oxford it was 1851. The Bouguer’s determination indicates an absorptive capacity in the atmosphere of Britain just midway between those of Oxford and Cairo. Seidel at Munich expresses “surprise” at finding his own results so nearly accordant with Bouguer’s. Although rather outside the domain of photometry in the strict sense, a word or two may be said here about recent attempts to measure the heat received from the stars, the first being made with the “radio-micrometer” of C. V. Boys. (Proc. Roy. Soc. 1890). This is an extremely delicate instrument for measuring radiant heat, and consists of a very light thermo-electric circuit (two tiny bars of antimony and bismuth soldered together at one edge, the outer edges being connected by a hoop of copper wire) suspended by a quartz fibre (a torsion fibre of the very greatest sensitiveness) in a strong magnetic field. A minute quantity of radiant heat falling on one of the junctions of the circuit sets up a current in the circuit, which thus rotates in the magnetic field until brought to rest by the torsion of the fibre. For use on the heavily bodies the radiant heat is collected to focus by a reflecting telescope (an object-glass would absorb it), and when the telescope is pointed to the moon the varying radiation from different parts of the disk is beautifully shown. No heat comes from the unilluminated portion, and of the illuminated portion the maximum is obtained from near the limb. But when pointed to the brightest stars no indications were obtained, although the instrument is sensitive enough to detect the heat from a candle more than a mile off. It seems certain that these indications of heat from the stars obtained by previous observers must be spurious. It is also manifest that to obtain satisfactory results even more sensitive apparatus must be devised, and by using a radiometer and the powerful resources of the Yerkes Observatory E. F. Nichols succeeded in 1888 and 1900 in obtaining indications of heat from Arcturus and Vega, as well as from Jupiter and Saturn (Astronomical Journ. xiii. p. 103), the heat received being comparable with that from a candle 6 m. away.

We may place alongside this result that obtained by W. J. Dibdin (Proc. Roy. Soc. April 1892), who compared candle-light with twenty-one stars ranging to the sixth magnitude, and found the light of a second magnitude star equal to that of a candle at 1260 ft.

(H. H. T.)

PHRAATES (Phraiates; Pers. Frakāt, modern Parhāt), the name of five Parthian kings.

1. PHRAATES I., son of Priapadius, reigned c. 175-170 B.C. He subdued the Mardii, a mountainous tribe in the Elburz (Justin xii. 5; Isid. Charac. 7). He died young, and appointed as his successor not one of his sons, but his brother Mithradates I. (Justin xii. 5).

2. PHRAATES II., son of Mithradates I., the conqueror of Babylonia, reigned 138-127. He was attacked in 130 by Antiochus VII. Sidetes, who, however, in 129 was defeated and killed in a great battle in Media, which ended the Seleucid rule east of the Euphrates (see Seleucid Dynasty). Meanwhile the kingdom was invaded by the Scythians (the Tochari of Bactria), who had helped Antiochus. Phraates marched against them, but was defeated and killed (Justin xiii. 1; Johannes Antioch. fr. 66).

3. PHRAATES III., “the God” (Phleghon, fr. 12 ap. Photius cod. 97 and on some of his coins), succeeded his father, Sanatruces, in 70 B.C., at the time when Lucullus was preparing to attack Tigranes of Armenia, who was supreme in western Asia and had wrested Mesopotamia and several vassal states from the Parthian kingdom. Naturally, Phraates declined to assist Mithradates of Pontus and Tigranes against the Romans (see Tigranes). He supported his son-in-law, the younger Tigranes, when he rebelled against his father, and invaded Armenia (65 B.C.) in alliance with Pompey, who abandoned Mesopotamia to the Parthians (Dio. Cass. xxxvi. 45, 51; Appian, Mithr. 104; Liv. Epit. 100). But Pompey soon overrode the treaty; he acknowledged the elder Tigranes, took his son prisoner, occupied the vassal states Gordyane and Osroène for the Romans, and denied the title of “king of kings,” which Phraates had adopted at home, to the Parthian king (Plut. Pomp. 33, 38; Dio. Cass. xxvii. 5 seq.). About 57 Phraates was murdered by his two sons, Ordes I. and Mithradates III.

4. PHRAATES IV., son of Ordes I., by whom he was appointed successor in 37 B.C., after the death of Pacorus. He soon murdered his father and all his thirty brothers (Justin xili. 5; Plut. Cass. 33; Dio Cass. xili. 23). He was attacked in 36 by Antonius (Mark Antony), who marched through Armenia into Media Atropatene, and was defeated and lost the greater part of his army. Believing himself betrayed by Artavases, king of Armenia, he invaded his kingdom in 34, took him prisoner, and concluded a treaty with another Artavases, king of Atropatene. But when the war with Octavianus Augustus broke out, he could not maintain his conquests; Phraates recovered Atropatene and drove Artaxes, the son of Artavases, back into Armenia (Dio. Cass. xili. 24 sqq., 39 seq., 44; cf. liv. 10; Plut. Antonius, 37 seq.). But his many cruelties Phraates had roused the indignation of his subjects, who raised Tiridates II. to the throne in 32. Phraates was restored by the Scythians, and Tiridates fled into Syria. The Romans hoped that Augustus would avenge the defeat of Crassus on the Parthians, but he contented himself with a treaty, by which Phraates gave back the prisoners and the conquered eagles (20 B.C., Mon. Anc. 5, 40 sqq.; Justin xili. 5); the kingdom of Armenia also was recognized as a Roman dependency. Soon afterwards Phraates, whose greatest enemies were his own family, sent five of his sons as hostages to Augustus, thus acknowledging his dependence on Rome. This plan he adopted on the advice of an Italian concubine whom he made his legitimate wife under the name of “the goddess Musa”; her son Phraates, commonly called Phraataces (a diminutive form), he appointed successor. About 4 B.C. he was murdered by Musa and her son (Joseph. Ant. xviii. 2-4).

5. PHRAATES V., or PHRATAACES, the younger son of Phraates IV. and the “goddess Musa,” with whom he is associated on his coins. Under him a war threatened to break out with Rome about the supremacy in Armenia and Media. But when Augustus sent his adopted son Gaius Caesar into the east in order to invade Parthia, the Parthians preferred to conclude a
PHRANTZA—PHRENOLOGY

treaty (A.D. 1), by which once again Armenia was recognized as in the Roman sphere (Dio, Cass. iv. 10; Velleius ii. 102). Soon after Phraortes and his mother were slain by the Parthians, about A.D. 5 (Joseph. Ant. xviii. 3. 4).

(PH) 

PHRANTZA, GEORGE [GEORGIOS PHRANTZES] (1401–c. 1477), the last Byzantine historian, was born in Constantinople. At an early age he became secretary to Manuel II. Palaeologus, in 1432 protosvetiarius (great chamberlain), in 1446 praefect of Sparta, and subsequently great logothete (chancellor). At the capture of Constantinople by the Turks (1453) he fell into their hands, but managed to escape to Peloponnesus, where he obtained protection at the court of Thomas Palaeologus, despot of Achaeae. After the downfall of the Peloponnesian princes (1460) Phrantza retired to the monastery of Tarchanites in Corfu. Here he wrote his Chronicle, containing the history of the house of the Palaeologoi from 1285–1476. It is a most valuable authority for the events of his own times.

Editions by I. Bekker (1838) in the Corpus scriptorum hist. byz., and in J. P. Migne, Patrologia graeca, vii. 2617–2618; see also C. Krumbacher, Geschichte der byzantinischen Literatur (1897).

PHRAORTES, the Greek form of Fravartish, king of Media. According to Herodotus (i. 102) he was the son of Deioces, and began the Median conquests. He first subdued the Parthians, and then a great many other peoples of Asia, till at last he attacked the Assyrians, but was defeated and killed in a battle, after a reign of twenty-two years (about 640–625 B.C.; but perhaps, as G. Rawlinson supposes, the fifty-three years of Deioces ought in reality to be transferred to him). From other sources we obtain no information whatever about Phraortes; but the data of the Assyrian inscriptions prove that Assur-bani-pal (see BABYLONIA AND ASSYRIA), at least during the greater part of his reign, maintained the Assyrian supremacy in Western Asia, and that in 645 he conquered Susa. The Medians too were subject to him as far as the Elburz and the central Iranian desert.

When after the assassination of Smerdis all the Iranian tribes, the Babylonians and the Armenians rebelled against Darius and the Persian rule, "a man of the name of Fravartish (i.e. Phraortes), a Mede, rebelled in Media and spoke to the people thus: I am Khshathira, of the family of Uvakhshata (Cyaxares)." He reigned for a short time, but was defeated by Hydarnes, and afterwards by Darius himself, taken prisoner in Rhagae (Rai), and executed in Ecbatana (320 B.C.; see inscription of Darius at Behistun). (Ed. M.)

PHRENOLOGY, (from Gr. φρήν, mind, and μάγος, discourse), the name given by Thomas Ignatius Forster to the empirical system of psychology formulated by F. J. Gall, and developed by his followers, especially by J. K. Spurzheim and G. Combe, by whom it was named "cranioscopic," "craniology," "physiognomy" or "zoonomy." The principles upon which it is based are five: (1) the brain is the organ of the mind; (2) the mental powers of man can be analysed into a definite number of independent faculties; (3) these faculties are innate, and each has its seat in a definite region of the surface of the brain; (4) the size of each such region is the measure of the degree to which the faculty seated in it forms a constituent element in the character of the individual; (5) the correspondence between the outer surface of the skull and the contours of the brain-surface beneath is sufficiently close to enable the observer to recognize the relative sizes of these several organs by the examination of the outer surface of the head. It professes primarily to be a system of psychology, but its second and more popular claim is that it affords a method whereby the disposition and character of the subject may be ascertained.

History.—That the phenomena of mind are in some measure connected with the action of the brain has been recognized from a very early age of philosophy. It is true that Aristotle

In his view, as in that of most of the earlier writers of other nations of antiquity, the heart is the seat of life; to it, not to the brain, the Hebrew writers refer thoughts and emotions, while they considered judgment as seated sometimes in the head, sometimes in the kidneys. This was likewise the teaching of the ancient Egyptian philosophy; and hence, while many rites were practised and prayers offered for the preservation of the heart of the deceased, there were none for the conservation of the brain. We learn from Diogenes Laertius that Pythagoras held more accurate physiological views, as he taught that the mind and the intellect have their seat in the brain. The theory of Hippocrates was Pythagorean rather than Aristotelian, for, although in one passage in his work De coelo he expresses himself doubtfully, yet elsewhere he clearly states that he considers the brain to be the index and messenger of the intellect. The cerebral seat of sense-perception is also taught by Plato, who puts into the mouth of Socrates the theory that the brain is the organ affected by the senses, whereby memory and opinion arise, and from whence knowledge springs. The classic poets also notice this dependence of mind on brain; for example, in the Clouds (415). Such theories are common among the philosophers. The two founders of anatomical science, Erasistratus and Herophilus, who lived in the days of Ptolemy Soter, taught not only that the brain was the seat of sensation and of intellect, but also that there was therein a certain degree of localization of function. Erasistratus believed that the sensory nerves arose from the brain-membranes, the motor from the cerebral substance. Herophilus was apparently the first who held that the vital forces resided in and circulated from the ventricles of the brain, at least so we gather from Celsus and the other authors who have preserved his views. By the influence of the writings of Galen, which directly teach that the brain is the seat of soul and intellect the Pythagorean doctrine prevailed among the later philosophers. According to the Galenical theory the animal spirits have their origin in the ventricles of the brain, and pass into the heart from which they are conveyed by the arteries to the various parts of the body. Thus the heart, having in one place (vii. 150) refers their origin to the brain-substance, but the ventricular theory was that adopted by his followers, some of whom suggested that there was some relation between the shape of the head and the character and disposition of the mind. The Arabian physicians Averroes and Rhazes adopted the Galenical doctrine and developed the hypothesis of a fourfold ventricular localization of faculties, which the Greeks had originated. Avicenna added to these a fifth region. Such of the early Christian authors as referred in

2 In the Chaldee portion of Daniel (ii. 28, iv. 5, vii. 1) visions and thoughts are referred to the heart, and we see Nasier on the physiological relations of the heart in Zeitschr. f. psychische Aeste (1818), vol. i. A few of the later medical writers express similar views; see Santa Cruz, Opuscula medica, Madrid (1624).

3 History of the head, ch. xxxvi. xxxi.

5 De morbo sacro, in Opp. ed. Kühn, i. 612 seq.; also Epist. iii. 834. Among later writers Licetius of Genoa taught the co-extension of the brain and heart, and of the brain and heart of the heart; Priscian (1616). In this connexion may be noted a curious work by Schegkius, Dialogus de animae principali, Aristotelis et Galeni ratione praesertim quibus sile cordis, hic cerebro, principatum attribuit (Tubingen, 1642).

6 De animalibus, ed. Volpi, Paris (1853). ch. xiv., p. 128. See also Hakker's Bibl. anat., i. 30.

7 De usu partium, ed. Kühn, iii. 700—702 μὲν οὖν ἀπόκειται τοῦ λογισμοῦ φυσικῶν σφαιρῶν τοῦ ἑνὶ καὶ κατά προτέρευς ἒνος τοῦ τούτοις χρήσει. In his Definitions medicinae (467, xix. 450) he says that the brain has a φυσικῆς ὑποστάσεως, but does not specify in what the power inheres.

9 Comment. in Arist., Latin tr. (Venice, 1550), vi. 73.

10 "Imaginatio quidem in diencephali ventriculis anterioribus perficit. Cogitatio vero in medio expleatur. Memoria autem posteriori possidet ventriculum." De re medico, Gérard's trana. (Basil, 1534), 1.9.

11 Lib. canons (1507), p. 19, and De naturalibus, c. 6.
PHRENOLOGY

The latter regarded the convoluted surface of the cerebrum as the seat of the memory and the will, the convolutions being intended to retain the animal spirits for the various acts of imagination and memory. Imagination he described as existing in the corpus callosum, sense-perception in the corpus striatum, and *impetus et perturbation* in the basal parts of the cerebrum above the crura. The thalami he regarded as the centres of sight and the cerebellum of involuntary acts. Succeeding anatomists simply varied these localizations according to their respective fancies. G. M. Lancisi placed sense-perception in the corpus callosum, R. Vieuxens in the centrum ovale majus. R. Descartes supposed the soul to be seated in the pineal gland, others in the brain-commissures especially the pons Varolii. Meyer considered abstract ideas to arise in the cerebellum, and memory to have its seat at the roots of the nerves.

Of later writers three deserve special notice, as having largely prolonged the phrenological line of inquiry. J. A. Unzer, of Halle, in his work on physiology extended the pre-existing theories of localization. Metzger, twenty years before the publication of Prochaska's work, had proposed to make a series of observations on the anatomical characters of the brains of persons of marked intellectual peculiarity; but apparently he did not carry this into effect. In a more special manner Prochaska of Vienna may be looked upon as the father of phrenology, as in his work on the nervous system, published in Vienna in 1784, are to be found the g anyone who reads it.
degree of popularity that in 1832 there were twenty-nine phrenological societies in Great Britain, and several journals devoted to phrenology in Britain and America; of these the Phrenological Journal, a quarterly, edited chiefly by George Combe with aid from others of the Edinburgh confraternity, notably Sir George Mackenzie and Macnish. "the modern Pythagorean," lived from 1823 to 1847, through twenty volumes. The controversy in many places was heated and often personal, and this largely increased the popular interest. In the Edinburgh Review the theory was severely criticized by Thomas Brown, and afterwards in a still more trenchant manner by Jeffrey. In Blackwood it was ridiculed by Professor John Wilson. Being a subject which lent itself easily to burlesque, it was parodied cleverly in a long rhyme by two authors, "The Cranial," 87 pages long, published in 1817, while, on the other hand, verse was pressed into its service in the rhyme "Phrenology in Edinburgh" in 1824. The best defence of the system was that by Cheneviex in the third number of the Foreign Quarterly, afterwards reprinted with notes by Spurzheim.

The Faculties and their Localities.—The system of Gall was constructed by a method of pure empiricism, and his so-called organs were for the most part identified on slender grounds. Having selected the place of a faculty, he examined the heads of his friends and cast of persons with that peculiarity in common, and in them he sought for the distinctive feature of their characteristic trait. Some of his earlier studies were made among low associates, in gaols and in lunatic asylums, and some of the qualifications located by him were such as tend to become perverted to crime. These he named after their excessive manifestations, mapping out organs of murder, theft, &c.; but as this cast some discredit on the system the names were changed by Spurzheim, who claimed as his the moral and religious considerations associated with it. Gall marked out on his model of the head the places of twenty-six organs as round enclosures with vacant interspaces. Spurzheim and Combe divided the whole scalp into oblong and conterminous patches (see the accompanying figures). Other methods of division and other names have been suggested by succeeding authors, especially by Cox, Sidney Smith (not Sydney), Toumlin Smith, K. G. Carus of Dresden, Don Mariano Cubi i Solar, W. B. Powell of Kentucky, J. R. Buchanan of Cincinnati, Hittel of New York. Some, like the brothers Fowler, raise the number of organs to forty-three; but the system of Spurzheim and Combe is that which has always been most popular in Britain.

Spurzheim separated the component faculties of the human mind into two great groups and subdivided these as follows:

I. Feelings, divided into—
1. Propensities, internal impulses inviting only to certain actions.
2. Sentiments, impulses which prompt to emotion as well as to action.
   A. Lower—those common to man and the lower animals.
   B. Higher—those proper to man.

II. Intellectual faculties.
1. Perceptive faculties.
2. Reflective faculties.

In the following list the locality and the circumstances of the first recognition of the organ are appended to the names, which are mostly the inventions of Spurzheim. Gall's names are placed in brackets.

1. Amativeness (Instinct de la génération), median, below the inion; first determined by Gall from its heat in an hysterical widow, supposed to be confirmed by many observations, and referred to the cerebellum.
2. Philoprogenitiveness (Amour de la progéniture), median, on the squama occipitis, and selected as the organ for the love of children because this part of the skull is usually more prominent in apes and in women, in whom the love of children is supposed to be stronger than in men.
3. Concentrativeness, below the obelion and over the lambda. This is a region of uncertain function, unnoticed by Gall, but described as Inhabitive by Spurzheim, because he found it large in a clergyman of his acquaintance.
4. Adhesive (Amitié), over the lateral area of the lambdoidal suture. This region was prominent in a lady introduced to Gall as a model of friendship, and is said by him to be the region where persons who are closely attached put their heads together.
5. Combative (Instinct de la défense), above the asterion; it was found by Gall by examining the heads of the most quarrelsome of his low companions whom he had beforehand stimulated by alcohol. It was verified by comparing this region with the same part of the head of a quarrelsome young lady.
6. Destructiveness (Instinct carnassier), above the ear meatus. This is the widest part of the skulls of carnivorous animals, and was found large in the head of a student so fond of torturing animals that he became a surgeon, also large in the head of an apothecary who became an executioner.
6a. Alimentiveness, over the temporal muscular and above the ear. Hoppe describes it as being large in a gourmand acquaintance, and he therefore supposes it to be the origin of selecting food.
6b. Secretiveness (Ruse, Finesse), the posterior part of the squamous suture.
6c. Acquisitiveness (Sentiment de la propriété), on the upper edge of the front half of the squamous suture. This part of the head Gall noticed to be prominent in the pickpockets of his acquaintance.
7. Constructiveness (Sens de mécanique), on the stephanion; detected by its prominence on the heads of persons of mechanical genius. It was found large on the head of a milliner of uncommon tact and on a skull reputed to be that of Raphael.
The organ of Vitaliveness, or love of life, is supposed by Combe to be seated at the base of the skull. To this locality Herophilus referred most of the intellectual powers.

Lower Sentiments.
10. Self-esteem (Orgueil, fierté), at and immediately over the obelion; found by Gall in a beggar who excused his poverty on account of his pride. This was confirmed by the observation that proud persons held their heads backwards in the line of the organ.
11. Love of Approbation (Vaniété), outside the obelion; the region in which Gall saw a protuberance on the head of a lunatic who fancied herself queen of France.
12. Cautionness (Circrespection), on the parietal eminence; placed here because an ecclesiastical hesitating disposition and a vacillating councillor of state had both large parietal eminences.
PHRENOLOGY

Superior Sentiments.

13. Benevolence (Boné), on the middle of the frontal bone in front of the coronal suture; here Gall noticed a rising on the head of the highly commended servant of a friend, as well as on a benevolent schoolmate who nursed his brothers and sisters when they were ill. He supposed the eminence referred the memory or powers.

14. Veneration (Sentiment religieux), median at the bregma. Gall noted when visiting churches that those who prayed with the greatest fervour were prominent in this region, and it was also prominent in his own family.

15. Consciousness. Believingness (Forster) unknown to Gall; recognized by Spurzheim usually from its deficiency, placed behind the last and the parietal eminence.

16. Firmness (Esprit caustique), on the sagittal suture from behind the bregma to the front of the obelon. Lavater first pointed out that persons of determination had lofty heads.

17. Hope, not regarded as primary by Gall, who believed hope to belong to the forebrain and a function of every faculty which desires and left this territory unallocated.

18. Wonder, said to be large in vision-seers and many psychic researchers. A second similar organ placed between this and the next is called Mysterizingness by Forster, and is said to be the seat of outlandishness and for fantasy.

19. Ideality (Poésie), noted by Gall from its prominence in the busts of poets; said to be the part touched by the hand when composing poetry.

20. Wit (Esprit d’imiter), the frontal eminence, the organ of the sense of the ludicrous, prominent in F. Rabelais and J. Swift.

21. Initiation (Faculté d’imiter), disposition to mimicry, placed between Benevolence and Wonder.

Perceptive Faculties.

22. Individuality, over the frontal sinus in the middle line; the capacity of recognizing external objects and forming ideas themself; said to have been large in Michelangelo, and small in the Scots.

23. Form (Mémoire des personnes), capacity of recognizing faces; gives a wide interval between the eyes; found by Gall in a squinting girl. Certains had a prominence of forebrain.

24. Size, over the trochea at the orbital edge; described by Spurzheim and Vinmont as the capacity of estimating space and distance.

25. Sight, outside the last on the orbital edge and, like it, over the frontal sinus. The prominence of ridge here is due to large sinus or a projecting bone. Certain old writers, such as Strato Physicus, located the whole intellect in this ridge.

26. Colour, also on the orbital edge external to the last.

27. Sense of locality (Sens de localité), placed above Individuality on each side, and corresponding to the upper part of the frontal sinus and to the region immediately above it.

28. Number, on the external angular process of the frontal bone, large in a calculating boy in Vienna.

29. Order, internal to the last, first noted by Spurzheim in an orderly idiot.

30. Eventuality (Mémoire des choses), the median projection above the glabella, supposed to be the seat of every possibility.

31. Time, below the frontal eminence and a little in front of the temporal crest.

32. Tune (Sens des rapports des ions), on the foremost part of the temporal muscle, where Gall noticed a bugle on the head of a musical prologue of five.

33. Language (Sens des mots), behind the eye. This was the first organ noticed by Gall, as a clever schoolfellow, quick at languages, had prominent eyes. Old authors had noted the connection between prominent eyebrows and mental development; thus Gazzali and Synensius Medicus Cyprus place the intellect and soul behind the eyebrows.

Reflective Faculties.

34. Comparison (Sagacité comparative), median, at the top of the bare region of the forehead, where a savant friend of Gall’s, fond of analogies, had a prominent brow.

35. Sound (Écoute clindipique), the eminence on each side of Comparison, noticed on the head of Fichte and on a bust of Kant, the seat of the faculty of correlating causes and effects.

The first identification of each organ was made by an induction from very limited data, but the founders and exponents of the system lacked all available instances wherein enlargements of each of these regions coexisted with increased powers of the faculty supposed to reside therein, and in some cases they have demonstrated coincidences of a surprising nature. When, however, such do not exist, a common excuse is found by reference to the inductive article of temperament, or by a supposed explanation of the faculty in question as not simple but produced by the co-operation of other influences. Thus, as Sheridan’s bump of wit was small, he is said not to have been truly witty; but to have had comparison and memory strongly developed. The girl Labrosse (described in Férussac’s Bulletin for October 1831), who exhibited strong amativeness but had a rudimentary cerebellum, is said to have obliterated it by over-use. Thurtell, a cold-blooded murderer, whose organ of benevolence was large, is said to have been half-a-guinea to a friend, &c.

The method whereby the sizes of organs are estimated is arbitrary and is determined by the regions indefinitely. The attempts of Nicol, Stratton and Wight to devise mechanical and accurate modes of measurement have not been very successful and have not found favour with the professional phrenologist.

Anatomical Aspect of Phrenology.—The phrenological controversy served the useful purpose of stimulating research into the anatomy of the brain; but we owe very little of solid progress to the advocates of the system. Gall is the only writer of his creed in whose works original observations of value are to be found, and Dr B. Holländer has cited many interesting and carefully recorded anatomical and clinical facts in his writings. Although the study of the surface of the cerebrum is of the essence of phrenology, yet nowhere in the circle of phrenological literature are the convolutions of the brain accurately described; our knowledge of their order and disposition comes from the first attempts of the phrenologist. The first real step towards their systematic description was made by L. Rolandi, who in 1830 described the fissure to which his name is attached, and very little advance was made until the publication of 1856 of L. P. Gratiolet’s and Huschke’s memoirs. These works for the first time placed the description of the surface of the brain, imperfectly attempted by L. A. Desmoulins in 1825, on a satisfactory basis.

A description of the anatomy of the brain is given under the heading Brain, so it is necessary here only to refer to points not included in that account.

1. Any psychological theory which correlates brain-action and mentality requires a correspondence between brain-size and mental power; and, speaking generally, the brains of those whose capacities are above the average are larger than those of the general run of their fellow-men.

2. Direct measurements of the relative developments of different portions of brains are difficult and troublesome to make; but their importance to phrenologists is so great that it is remarkable that no attempts to obtain any such were made by them. The series given by Wager of the relative sizes of the cerebral lobes of four brains is almost the only record of importance in this direction, and is appended.

From this it appears that the woman exceeded Gauss in perceptiveness, the man in reflective observation, and the two in the forebrain; and fell below the worker in propensities. It must be said, however, that the phrenological divisions do not accurately coincide with the anatomical. It would furnish important physiological data if the brains of men distinguished for special qualities were examined in this or some comparable way.

1. Della Struttura degli emisferi cerebrali (Turin, 1830).

3. H. Schädel, Hirn, und Seele (Jena, 1856).

5. Rivista sperimentale di freniatria (1885), iii. 193; ibid. iv. 403; Archiv für Anthropologie (1879), xi. 280.
identical convolutions in different brains consist of nerve-cells with precisely the same connexions. The convoluted arrangement results from growth of brain-surface under constraint, hence as the different tracts of surface undergo proportionate overgrowth they may fold along different lines. The occurrence of small differences in the rate of overgrowth, testified to by the varieties of the resulting pattern, can hardly fail to cause considerable alteration in the place of definite territories of grey cells. Some method for the determination of the limits of these shifting of place is required before conclusions can be drawn as to their existence or non-existence.

4. The comparison of the rate of growth of brain with the development of mental faculties is important not only to the phrenologist but to the psychologist. No observations on this point were made by Spurzheim, although several to only refer to the fact and rather crude observations of the earlier anatomists. We have, however, recently learned from the researches of T. L. W. von Bischoff, Tuzex, Cunningham, and S. Exner many particulars as to the rate and duration of growth of the average brain weights, the average weight of the body, and averages about 11 oz. For the first year brain-growth and consequent expansion of the skull proceed with great rapidity, the growth during a large part of this period averaging one cubic centimetre daily. The increase is chiefly due to the rapid development of medullated nerve-fibres, which are deficient in the foetal brain. During the second and third years growth takes place more slowly, the occipital and parietal lobes growing more than the frontal and temporal.

During these and the four succeeding years the base elongates commensurately with the increasing depth of the face. In the sixth and seventh the frontal lobes grow faster than the parietal, and the average brain weights are attained, as attested by the measurements of H. V. Fries, being of the body as 1:20. In the period between seven years and puberty growth is slight, but at puberty the whole brain grows actively, especially the frontal lobes. This activity lasts until about eighteen years, and it is then that the brain begins to reach its maximum size until about thirty, from a little after which period the brain tends to diminish towards senility.

5. The estimation of the relative development of grey and white matter is important to any theory of cerebral dynamics which allocates functions specifically diverse to each separate part of the brain-surface; but no attempt has been made by the phrenologist to obtain precise results in this direction, nor even to determine the proportion of white to grey matter. The recently introduced method of Bourquin and B. Danilewicz, based upon the differing specific gravities of grey and white matter, promises to give definite information as to the relative amounts of these elements of the brain; but further experiments are needed to perfect the method.

6. The relations, if any, between the alterations which take place in the shape and position of the head and alterations in brain-surface have been investigated by E. Huschke, Heffler, W. C. Turner, S. Combe, and others. S. Exner has reported that his organ of causality had enlarged with increasing use, and a list of cases of similar alternations of head-shape is given by Deville (Phren. Journ., xiv. 32), most of which are simply age-changes. The observations of Beveridge (Phil. Trans. 1870) are there no exact measurements recorded which indicate the occurrence of topical increases of a normal brain, in special directions coincident with the cultivation of definite faculties. All that we know is that the brain supposed to have been in active use was found to be larger; and the careful measurements of George Combe in such cases as were available to him showed no appreciable alterations in adult heads even at long intervals of time (see also Andrew Combe, Phren. Journ. 1841, x. 414).

7. In a phrenological want of knowledge of the topography of the brain-surface was necessarily correlated with ignorance of the exact relations of the convolutions to the cranial bones; these have been carefully worked out by E. Huschke, Heffler, W. C. Turner, S. Combe, and others. S. Exner has reported that his organ of causality had enlarged with increasing use, and a list of cases of similar alternations of head-shape is given by Deville (Phren. Journ., xiv. 32), most of which are simply age-changes. The observations of Beveridge (Phil. Trans. 1870) are there no exact measurements recorded which indicate the occurrence of topical increases of a normal brain, in special directions coincident with the cultivation of definite faculties. All that we know is that the brain supposed to have been in active use was found to be larger; and the careful measurements of George Combe in such cases as were available to him showed no appreciable alterations in adult heads even at long intervals of time (see also Andrew Combe, Phren. Journ. 1841, x. 414).
PHRENOLOGY

539

and higher-lying grey portions of the nervous centres there is
an a priori presumption in favour of the extension of this principle
of localization. This has been premised on metaphysical as well
as on anatomical grounds. A. B. Bonnet long ago believed each
portion of the brain to have a specifically separate function, and
Herbert Spencer has said that "no physiologist can long resist
the conviction that different parts of the cerebrum subserve
different kinds of mental action. Localization of function is the
law of all organization; separateness of duty is universally
accompanied with separateness of structure, and it would be
marvellous were an exception to exist in the cerebral hemispheres.
It let it be granted that the cerebral hemispheres are the seats
of the higher psychical activities; let it be granted that among
these higher psychical activities there are distinctions of kind
which, though not definite, are yet practically recognizable, and
it cannot be denied, without going in direct opposition to
established physiological principles, that these more or less
distinct kinds of psychical activity must be carried on in more
or less distinct parts of the cerebral hemisphere." 1

For a masterly review of the old and the new association and
localization theories, see W. Wundt’s Grundzüge der physisch
Psychologie, i. 289 sqq.; also the same author’s Essays, Leipzig
(1888), pp. 109 sqq.

There is a large evidence of the existence of some form of localization of function. So little is known of
the physical changes which underlie psychical phenomena, or
indeed of the succession of the psychical processes themselves,
that we cannot as yet judge as to the nature of the mechanism
of these centres. So much of the psychic work of the individual
life consists in the interpretation of sensations and the translation
of these into motions that there are strong a priori grounds
for expecting to find that much of the material of the nerve-
centres is occupied with this kind of work, in the present
conflict of experimental evidence it is safer to suspend judgment.
That these local areas are not centres in the sense of being
indispensable parts of their respective motor apparatuses is
clear, as the function abolished by ablation of a part returns,
though tardily, so that whatever superstition the removed
region exercised apparently becomes assumed by another part
of the brain. 1 Experimental physiology and pathology, by
suggesting other functions for parts of the brain-surface, are
directly subversive of many details of the phrenology of
Gall and Spurzheim.

Psychological Aspect.—The fundamental hypothesis which
underlies phrenology as a system of mental science is that mental
phenomena are resolvable into the manifestations of a group of
separate faculties. A faculty is defined as "a convenient
expression for the particular states into which the mind enters
when influenced by particular organs; it is applied to the feelings
as well as to the intellect, thus the faculty of benevolence means
every mode of benevolence induced by the organ of benevolence"
(Combe). In another work the same author says it is "used
to denote a particular power of feeling, thinking, perceiving,
composing, etc., etc., existing independently of any other organ.
This denomination is contained in the definition that the exercise of a faculty is the
physical outcome of the activity of the organ, and in several
of the standard works this is illustrated by misleading analogies
between these and other organs; thus the organs of benevolence
and of firmness are said to be as distinct as the liver and pancreas.
The mind, according to another author, consists of the sum of all
the faculties. In this view the unity of consciousness is some-
what difficult to explain, and consequently there is assumed by
others a single unifying substratum, and on this the organs
are supposed to act; thus thoughts are defined as "relations of
the simple substance, mind, to certain portions of the
encephalon" (Welsh, Phren. Journ. i. 206). Gall himself believed
that there was but a single principle which saw, felt, tasted,
heard, touched, thought and willed (Fonctions du cerveau,
213); and the American exponent of phrenology, Caldwell,
says "the mind is as single in its power as it is in its substance;"
1 For cases, see La Rochefontaine, Archives de Physiologie (1883), 28;
Bianchi, La Psychiatrie, i. 97.

It is a quickening and operating principle, essential to all the
mental faculties, but does not, by any means, possess them
itself" (Elements, p. 16). It is not easy to understand the sup-
posed relation of this hypothetical substratum to the separate
faculties acting on it. It must be both immutable and uncon-
nected with the brain, as the whole two thousand million cells
supposed to exist in the cerebral hemispheres are all parceled
out among the faculties, and none are left for the unifying nous.

Each organ is considered as engaged, either independently
in bringing forth its own product, or collectively with others in
elaborating compound mental states, and according to their
several degrees of development and activity they are considered
capable of perceiving, conceiving, recollecting, judging or
imaging each its own subject. This mechanical conception of
the division of labour in the production of the phenomena
of mind has the charm of simplicity, but is attended with the
difficulty that arises in discriminating the operations of the
different organs one from the other. Phrenologists are apt to
be vague respecting the limits of the several faculties, as about
the boundaries of the separate organs. It was pointed out by
Jeffrey that the lines of demarcation between benevolence,
adhésiveness and philoprogenitiveness were indeterminate,
although the organs are not very close, and the same applies
to other organs.

It is unfortunate for the clearness of the definition that,
although historically the faculties were the first phenomena
noted, independent of and previous to their localization, yet
in the definition the faculties are defined in terms of their
localities.

The following arguments are adduced in favour of the funda-
mental separateness of the faculties: (1) analogy—elsewhere
in the animal economy division of labour is the rule; (2) the
variety of mental endowment observed among children before
they are influenced by education, and the inequalities in the
mental endowments of individuals; (3) the phenomena of
insanity, especially of monomania; (4) the varying periods at
which individual faculties attain their maximum development;
(5) the phenomena of dreams, and the awakening of a limited
number of faculties during them; (6) pain being felt in an organ
when it is overtaxed. 2

Such faculties are supposed to be primary—(1) as exist
in some animals and not in others, (2) as vary in their development
in the sexes, (3) as are developed in varying proportions with
regard to other faculties, (4) as may act separately from other
faculties, (5) as are not necessarily simultaneous with other
faculties in action, (6) as are hereditary, and (7) as may be singly
diseased.

According to the development of their powers mankind may
be divided into six classes: (1) those in whom the highest
qualities are largely developed and the animal qualities feeble;
(2) those with the reversed conditions developed, with large
animal and feeble intellectual and moral faculties; (3) those
in whom good and evil are in constant war, with active animal
and strong intellectual faculties and sentiments; (4) those partial
genres in whom the animal qualities are unusually developed, while
the intellectual are kept in check; (5) those who are above the
mediocre standard; (5) those men or below the mediocre standard; (6)
those with an unvarying standard of undistinguished mediocrity in all their faculties.

It is perhaps unfortunate that the word "faculty" has been
used in this sense of original power by phrenologists. It would
have been better to employ, as Mr Lewes suggests, the term
3 It is interesting in this connexion to note that in a case published
by Professor Hamilton in Brain (April 1884), where a tumour existed
on the occipital lobe, the pain was persistently referred to the fore-
head. In many similar cases are to be noticed among the records of
localized brain-lesions. Bearing on this point also it is worth noting,
that, for all that in nothing is the purely hypothetical nature of
phrenological description better realized than in the accounts of
what these authors call the "natural language of the faculties,"
—that poets are supposed to touch ideality when composing,
musicians to press on tone and time, and painters on form and
colour, when in the exercise of their arts! Yet we are greatly
taught this in the standard works on the subject.
PHRENOLOGY

"function" for the native activity of an organ, and to leave "faculty" for the expression of an acquired activity. "Faculty is properly limited to active power, and therefore is abusively applied to the mere passive affections of the mind." (Hamilton, Lectures, i. 177.)

An attempt has been recently made by Dr Bernard Holländer to correlate the doctrines of phrenology with the modern physiological and pathological observations which bear upon the localization of function. In his works The Mental Functions of the Brain, under the sub-title "The Revival of Phrenology" (1901), and in Scientific Phrenology (1902), the author endeavours to bring Gall's clinical and pathological instances into line with more modern observations. He deprecates the craniology of Gall, as far as it deals with mere "bumps," and honours him, with justice, as the recorder of many facts worth saving out of the wreck of his system; and he endeavours, though with doubtful success, to establish an unbroken connexion between phrenology, in the Greek sense, and our present knowledge of cerebral localization.

The substance of Holländer's first work is of two kinds. The one kind is a tabulated statement of many hundred cases of different forms of mania, with injury or disease limited to one portion of the brain; the other kind is a tabulated statement of cases of injury or disease limited to one faculty, by injury or excitation, or loss of some definite instinct or faculty of consciousness.

He divides the tabulated cases into mania into three groups: (i) Melancholia; (ii) Irascible Insanity, " Mania furiosa;" (iii) Mania with convulsions or fits of convulsions. For these three groups of cases he lays down the following rules: (i) Melancholia is associated with injury or disease of the parietal lobe of the brain, more particularly with injury or disease of the convulsions underlying melancholia: (ii) the supramarginal and angular convolutions; (iii) Mania furiosa is especially associated with injury or disease of the central portion of the temporal lobe. (iii) Mania with suspicion and delusions of persecution is especially associated with injury or disease of the posterior portion of the temporal lobe.

The second kind of cases, where injury or disease of the brain, strictly localized to one part or another of its grey matter, was followed by some peculiarity of mind - viz., excitation, excitation, or loss of some one instinct, habit, or faculty, includes cases of kleptomania, cases of voracious hunger, and thirst, cases of sexual desire excited or lost, and cases of loss of certain special memories, as of words, tunes, numbers and the like.

The collection of recorded cases, taken from a vast mass of clinical and pathological literature accumulated during the past century, have been arranged by Dr Holländer with great industry; so as to extend the limits of the study of cerebral localization, and to advance it from the observation of the motor areas and the special senses to the study of cerebral localization of mental and moral activity and of mental and moral activity and of mental and moral activity and of mental and moral activity and of moral activity. Modern physiology, from its objective point of view, is engaged over finer and finer issues of microscopic and experimental work; and, from its subjective point of view, is becoming more and more the product of a high degree of observation and reflection, and a statement of the developmental life of the brain in terms of increasing complexity. The motor centres, governing the voluntary purposeful movements of the body, are considered to be not simple motor centres but homogenous, but are on experimental grounds differentiated into sub-centres for the utterance of words, the recognition of words and the understanding of words; the visual centres are in like manner subdivided according to the consciousness involved in the complex act of vision. There is room, therefore, for a "higher phrenology," if it can show clear evidence in favour of the localization, in determining the regions of the brain, of the physical changes accompanying certain mental changes.

Of the two kinds of cases that Dr Holländer has tabulated, it cannot be said that the cases of mania are convincing. Some of them are altogether beside the mark; e.g. he quotes two cases of melanomania, merely over the left parietal bone, which were cured by an operation limited to the scalp, and excision of scar, removal of a small nerve-tumour of the scalp); in neither case was anything done to the skull or to the brain, but both patients were cured of the illness. Again, the acceptance of these rules as to the localization of these cases, and the thought involved in the localization of these kinds of mania, and this in turn involves assumptions which are wholly unwarranted by our present knowledge of the brain. Moreover, cases of mania are so common and so rare in the series of recorded cases, that it might be possible to find an equal number of cases which do not conform to his rules: we want conclusive, not packed cases. If 5000 consecutive fatal cases of these different kinds of mania, with the post-mortem record of each case, were tabulated, we should then begin to stand on surer ground. Again, though Dr Holländer sets out to argue well, he says that the facial and other movements, induced by direct electrical stimulation of certain convolutions are such as express the mental states which he attributes to those convolutions, yet this argument is insecure, partly because Sherrington's recent work, on the motor area of the anthropoid apes, has rendered it necessary to reconsider the present localization of the motor area in man, and partly because the interpretation of facial and other convulsions movements as representing this or that state of the emotions is always perilous. The second kind of cases, where injury or disease limited to one portion of the brain is followed by perversion, excitation, or loss of some special instinct or habit, is more valuable and more convincing; especially the cases of voracious hunger and thirst, those of true kleptomania, and those of the loss of certain special memories. It is not so easy to believe that the cerebellum is in any primary way associated with sexual desire: its position, its structure and its connexion with the other convolutions of the brain, suggest that movements seem clearly to indicate that its work is wholly subordinate and complementary to the work of the cerebral hemispheres; and the evidence deduced in favour of its being the "seat" of the sexual impulses hardly amounts to more than the probability that it may transmit or co-ordinate the performance of the sexual act.

Practical Application.—" Die Schädellehre ist allerdings nicht, so sehr Irrthum in der Idee als Charlatanerie in der Ausführung," says one of its most acute critics. Even though it could be found with the physiology and psychology of phrenology, it would not necessarily follow that the theory could be utilized as a practical method of reading character; for, although the inner surface of the skull is moulded on the brain, and the outer surface approximates to parallelism thereto, yet the correspondence is sufficiently variable to render conclusions therefrom uncertain. The spongy layer or diploe which separates the two compact tables may vary considerably in amount in different parts of the same skull, as in the cases described by Professor Humphry (Journ. of Anat. viii. 137). The frontal sinuses, that "apparatus appropriatum," is a reality, and not unfrequently of large size, and may wholly occupy the regions of five organs. The centres of ossification of the frontal and parietal bones, the dural crests of these and of the occipital bones also, differ in their prominence and different skulls. Premature synostoses of sutures mould the brain without doing much injury to its parts. In such cases there are compensating modifications in other directions modifying sometimes to an extreme degree the relation of brain-surface to skull-surface. The writer has found such displacements in extremely sphenophaenitic skulls; the same is true of accidental deformations due to pressure on the infantile skull before it consolidates. Artificial malformations alter the apparent skull shape considerably while they affect the relative development of the parts of the brain cortex but little. All these and other cogent reasons of a like kind, whose force can be estimated by those accustomed to deal with the component soft parts of the head, should lead phrenologists to be careful in precipitating relative brain-development from skull-shape. Psychology, physiology and experience alike contribute to discredit the practical working of the system and to show how worthless the so-called diagnoses of character really are. Its application throughout to what are its votaries is seldom worse than amusing, but it is capable of doing positive social harm, as in its proposed application to the discrimination or selection of servants and other subordinate officials. It has even been proposed to use it for the purposes of the guarantee society and for the selection of parliamentary representatives. The sarcastic suggestion which originated with Christopher North of moulding children's heads so as to suppress the evil and foster the good was actually repeated in good faith by a writer on phrenology, but the experience of the effects of malformation leads one to be sceptical as to the feasibility of this mode of producing a social Utopia.

The country named Phrygia in the better known period of history lies inland, separated from the sea by Paplagonia, Bithynia, Mycia and Lydia. Yet we hear of a Phrygian "thalassocracy" at the beginning of the 7th century B.C. The Troad and the district round Mt Sipylus are frequently called Phrygian, as also is the seaport Sinope; and a district on the coast between Sestus and the river Cius was regularly named Little Phrygia; names like Mygdonia, Doliones and Phryges or Briges, &c., were widely current both in Asia Minor and in Europe. The inference has been generally drawn that the Phrygians belonged to a stock widespread in the countries which lie round the Aegean Sea. There is, however, no conclusive evidence whether this stock came from the east over Armenia, or was European in origin and crossed the Hellespont into Asia Minor; but modern opinion inclines decidedly to the latter view.

According to Greek tradition there existed in early time a Phrygian kingdom in the Sangarius valley, ruled by kings among whom the names Gordius and Midas were common. It was known to the ancient Greeks of Ionia and the Troad as something great and half-divine. When the goddess appeared to her favourite Anchises she represented herself as daughter of the king of Phrygia; the Phrygians were said to be the oldest people, and their language the original speech of mankind; the Phrygian kings were familiar associates of the gods, and the heroes of the land tried their skill against the gods themselves; we hear of the well-walled cities of Phrygia and of the riches of its kings. Tradition is completely corroborated by archaeological evidence. In the mountainous region on the upper waters of the Sangarius, between Kutaiash Eski Shehr and Afun (Aphon) Karu Hassar, there exist numerous monuments of great antiquity, showing a style of marked individuality, and implying a high degree of artistic skill among the people who produced them. On two of these monuments are engraved the names of "Midas the King" and of the goddess "Kyble the Mother." Even the title "king" (άρχας) appears to have been borrowed by Greek from Phrygian.

It is impossible to fix a date for the beginning of the Phrygian kingdom. It appears to have arisen on the ruins of an older civilization, whose existence is revealed to us only by the few monuments which it has left. These monuments, which are found in Lydia, Phrygia, Cappadocia and Lycaonia, as well as in north and central Syria, point to the existence of a homogeneous civilization over those countries; they show a singularly marked style of art, and are frequently inscribed with peculiar names. The most notable of these is the original Gräberfeld, or "tomb field," which originated probably from a great Hittite kingdom, whose rule extended to Syria and the borders of Egypt. There can be traced in Asia Minor an ancient road-system, to which belongs the "royal road" from Sardis to the Persian capital, Susa (Herod. v. 55). The royal road followed a route so difficult and circuitous that it is quite unintelligible as the direct path from any centre in Persia, Assyria or Syria to the west of Asia Minor. It can be understood only by reference to an imperial centre far in the north. The old trade-route from Cappadocia to Sinope, which had passed out of use centuries before the time of Strabo (pp. 540, 546), fixes this centre with precision. It must be far enough west to explain why trade tended to the distant Sinope,6 hardly accessible behind lofty and rugged mountains, and not to Amissus by the short and easy route which was used in the Graeco-Roman period. This road-system, then, points distinctly to a centre in northern Cappadocia near the Halys. Here must have stood the capital of some great empire connected with its extremities, Sardis or Ephesus on the west, and the north, the European part of the east, the Hittite capital (Byblos) and the Cilican Gates on the Troad. The Phrygian capital would be expected to continue in use for a long time after the centre of power had changed to Assyria, and the old road-system had become circuitous and unsuitable.5 The precise spot on which the city stood is marked by the great ruins of Boghaz Keui, probably the ancient Pteria, of which the wide circuit, powerful walls and wonderful rock-structures make the site indisputably the most remarkable in Asia Minor. On this site Winckler found in 1907 the records of the Hittite kings who fought against Egypt and Assyria.

The ancient road from Pteria to Sardis crossed the upper Sangarius valley, and its course may be traced by the monuments of this early period. Close to its track, on a lofty plateau which overhangs the Phrygian monument inscribed with the name of "Midas the King," is a great city, inferior indeed to Pteria in extent, but surrounded by rock-structures quite as remarkable as those of the Cappadocian city. The plateau is 2 m. in circumference, and presents on all sides a perpendicular face of rock 50 to 200 ft. in height. This natural defence was crowned by a wall partly Cyclopean, partly built of large squared stones.5

The plateau is assumed to be the site of the capital of the Phrygian kingdom 6 of the Hittite tombs. It is expressly recorded the ryomos is a Lydian word. BasaNe resists all attempts to explain it as a purely Greek formation, and the termination assimilates it to certain Phrygian words.

Sinope was made a Greek colony in 751 B.C., but it is said to have existed long before that time.

When the Persians conquered Lydia they retained, at least for a time, this route, which they found in existence.

The stones have all fallen, but the line where they were fitted can be traced by any careful explorer. The small fortress Pishmish Kalessi is a miniature of the great city beside it. (See Petrit, Explor. Archéol, p. 169 and pl. viii.)
PHRYGIA

of the Sangarius valley, but at least one of the monuments in it seems to belong to the older period of Cappadocian supremacy, and to prove that the city already existed in that earlier time. The Phrygian kingdom and art therefore took the place of an older civilization. It is probable that the tradition of battles between the Phrygians and the Amazons on the banks of the Sangarius preserves the memory of a struggle between the two races and the victory of the Phrygians.

Of the monuments that exist around this city two classes may be confidently referred to the period of Phrygian greatness. That which is inscribed with the name of "Midas the King" is the most remarkable example of one class, in which a large perpendicular surface of rock is covered with a geometrical pattern of squares, crosses and meanders, surmounted by a pediment supported in the centre by a pilaster in low relief. In some cases a floral pattern occupies part of the surface, and in one case the two sides of the pediment are filled by two sphinxes of archaic type. In some of these monuments a doorway is cut; but it is usual so the doorway is usually closed, but in one case, viz. the sphinx monument just alluded to, the valves of the arch are thrown wide open and give access to a little chamber, on the back of which is sculptured in relief a rude image of the Mother-goddess Cybele, having on each side of her a lion which rests its forepaws on her shoulder and places its head against hers. Sometimes a grave has been found hidden behind the carved front; in other cases no grave can be detected, but it is probable that they are all sepulchral. The imitation of woodwork is obvious on several monuments of this kind. The second class is marked by the heraldic type of two animals, usually lions rampant, facing one another, but divided by a pillar or some other device. This type is occasionally found conjoined with the preceding; and various details common to both classes show that there was no great difference in time between them. The heraldic type is used on the monuments which appear to be the older, and the geometrical pattern is often employed on the inscribed monuments which are obviously later than the earliest uninscribed. Monuments of this class are carved on the front of a sepulchral chamber, the entrance to which is a small doorway placed high and inaccessible in the rocks. There are also many rock monuments of the Roman time.

Early Phrygian art stands in close relationship with the art of Cappadocia. The monuments of the type of the Midas tomb are obviously imitated from patterns which were employed in cloth and carpets and probably also in the tilework on the inside of chambers varying slightly according to the material. Such patterns were used in Cappadocia, and the priest in the rock-sculpture at Ibriz wears an embroidered robe strikingly similar in style to the pattern on the Midas tomb; but the idea of using the pattern as the Phrygians did seems peculiar to themselves. The heraldic type of the second class is found also in the art of Assyria, and was undoubtedly adopted by the Phrygians from earlier art; but it is used so frequently unadorned that Phrygian art is especially characteristic of that country. While Phrygian art is distinctly non-Oriental in spirit, its resemblance to archaic Greek art is a fact of the greatest importance. It is not merely that certain types are employed both in Phrygia and in Greece, but several favourite types in early Greek art can be traced in Phrygia, employed in similar spirit and for similar purposes. The heraldic type of the two lions is the device over the principal gateway of Mycenae, and stamps this, the oldest great monument on Greek soil, with a distinctly Phrygian character. Mycenae was the city of the Pelopidae, whom Greek tradition unhesitatingly declares to be Phrygian immigrants. A study of the topography of the Argive plain suggests the conclusion that Mycenae, published in Journ. Hell. Stud. (1885).

3 The inscriptions of Phrygia fall into two groups, which probably mark the sites of two cities about 16 m. distant from each other. Metropolis and Cnossus. One group lies round the villages of Yazili-Kay, Kumbet, Yapudak and Bakshish; the other beside Lyen, the ancient Demirli and Ayazin.

The heraldic type continues on gravestones down to the latest period of paganism. Carpets with geometrical patterns of the Midas-tomb style are occasionally found at the present time in the houses of the peasantry of the district.

Midea and Tiryas form a group of cities founded by an immigrant people in opposition to Argos, the natural capital of the plain and the stronghold of the native race. Midea appears to be the city of Mides, and the name is one more link in the chain that binds Mycenae to Phrygia. This connexion, whatever may have been its character, belongs to the remote period when the Phrygians inhabited the Aegean coasts. In the 8th and probably in the 9th century B.C. communication with Phrygia seems to have been maintained especially by the Greeks of Cyme, Phocaea and Smyrna. About the end of the 8th century Mides, king of Phrygia, married Damodice, daughter of Agamemnon, the last king of Cyme. Gyges, the first Mermnad king of Lydia (687-653), had a Phrygian mother. The worship of Cybele spread over Phocaea to the west as far as Massilia: rock monuments in the Phrygian style and votive reliefs of an Anatolian type are found near Phocaea. Smyrna was devoted to the Phrygian Meter Sipylene. It is then natural that the Homeric poems refer to Phrygia in the terms above described, and make Priam's wife a Phrygian woman. After the foundation of the Greek colony at Sinope in 751 there can be no doubt that it formed the link of connexion between Greece and Phrygia. Phrygian and Cappadocian traders brought their goods, no doubt on camels, to Sinope, and the Greek sailors, the Δαιμόνιοι of Miletus, carried home the works of Oriental and Phrygian artisans. The Greek alphabet was carried to Phrygia and Pteria, either from Sinope or more probably direct east from Cyme, in the latter part of the 8th century. The immense importance of Sinope in early times is abundantly attested, and we need not doubt that very intimate relations existed at this port between the Ionic colonists and the natives. The effects of this commerce on the development of Greece were very great. It affected Ionia in the first place, and the mainland of Greece indirectly; the art of Ionia at this period is almost unknown, but it was probably closely allied to that of Phrygia. A striking fact in this connexion is the use of a very simple kind of Ionic capital in one early Phrygian monument, suggesting that the "Ionic" column came to Greece over Phrygia. It is obvious that the revolution which took place in the relations between Phrygians and Greeks must be due to some great movement of races which disturbed the old paths of communication. Abel is probably correct in placing the inroads of the barbarous European tribes, Bithynians, Thyni, Mariandyni, &c., into Asia Minor about the beginning of the 9th century B.C. The Phrygian element on the coast was weakened and in many places annihilated; that in the interior was strengthened; and we may suppose that the kingdom of the Sangarius valley now sprang into greatness. The kingdom of Lydia appears to have become important about the end of the 8th century, and to have completely barred the path between Phrygia and Cyme or Smyrna. IONIAN maritime enterprise opened a new way over Sinope. The downfall of the Phrygian monarchy can be dated with comparative accuracy. Between 680 and 670 the Cimmerians in their destructive progress over Asia Minor overran Phrygia; the king Mides in despair put an end to his own life; and from henceforth the history of Phrygia is a story of slavery, degradation and decay, which contrasts strangely with the earlier legends. The catastrophe seems to have deeply impressed the Greek mind, and the memory of it was preserved. The date of the Cimmerian invasion is fixed by the concurrent testimony of the contemporary poets Archilochus and Callinus, of the late chroniclers Eusebius, &c., and of the inscriptions of the Assyrian king Eshar-haddon. The Cimmerians were finally expelled from Asia Minor by Alyattes before his war with the Medes under Cyaxares (590-585 B.C.). The Cimmerians, therefore, were ravaging Asia Minor, and presumably held possession of Phrygia, the only country where they achieved serious results. See Furthwangler, Goldfund von Vettersfelde, Winckel, Progr. (1884); Hogarth, &c., The Archeological Mission of British Museum, 1901. The closest analogies of old Phrygian art are to be found in the earliest Greek bronze work in Olympia, Italy and the northern lands. Hipponax, fr. 36 (49), proves that a trade-route from Phrygia over the Carian and Mæander to Miletus was used in the 6th century.
complete success, till some time between 610 and 590 Phrygia then fell under the Lydian power, and by the treaty of 585 the Halys was definitely fixed as the boundary between Lydia and Media (see Lydia and Persia). The period from 675 to 585 must therefore be considered as one of great disturbance and probably of complete paralysis in Phrygia. After 585 the country was ruled again by its own princes under sujection to Lydian supremacy. To judge from the monuments, it appears to have recovered some of its old prosperity; but the art of this later period has to a great extent lost the strongly marked individuality of its earlier bloom. The later sepulchral monuments belong to a class which is widely spread over Asia Minor from Lycia to Pontus. The graves are made inside a chamber excavated in the rock, and the front of the chamber imitates a house or temple. No attempt is made to conceal the entrance or to render it inaccessible. The architectural details are in some cases unmistakably copied, without intentional modification, from the architecture of Greek temples; others point perhaps to Persian influence, while several—which are perhaps among the early works of this period—show the old freedom and power of employing in new and original ways details partly learned from abroad. This style continued in use under the Persians, under whose rule the Phrygians passed when Cyrus defeated Croesus in 546, and lasted till the Roman period. One monument appears to presuppose a development of Greek plastic art later than the time of Alexander and is almost certainly of the Roman time. It would, however, be wrong to suppose that the influence of truly Hellenic art on Phrygia began with the conquest of Alexander. Under the later Mermnad kings the Lydian empire was penetrated with Greek influence, and Xanthus, the early Lydian historian, wrote his history in Greek. Under the Persian rule perhaps it was more difficult for Greek manners to spread far east; but we need not think that European influence was absolutely unfelt even in Phrygia. The probability is that Alexander found in all the large cities a party favourable to Greek manners and trade. Very little is to be learned from the ancient writers with regard to the state of Phrygia from 585 to 300. The slave-trade flourished: Phrygian slaves were common in the Greek market, and the Phrygian names Mida and Manes were stock-names for slaves. Herodotus (i. 14) records that a king Midas of Phrygia dedicated his own chair at Delphi; the chair stood in the treasury of Cypselus, and cannot have been deposited there before 680 to 660 B.C. It is not improbable that the event belongs to the time of Alyattes or Croesus, when Greek influence was favoured throughout the Lydian empire; and it is easy to understand how the offering of a king Midas should be considered, in the time of Herodotus, as the earliest made by a foreign prince to a Greek god. The Phrygian troops in the army of Xerxes were armed like the Armenians and led by the same commander.

It is to be presumed that the cities of the Sangarius valley gradually lost importance in the Persian period. The final catastrophe was the invasion of the Gauls about 270 to 250; and, though the circumstances of this invasion are almost unknown, we may safely reckon among them the complete devastation of northern Phrygia. At last Attalus I. settled the Gauls permanently in eastern Phrygia, and a large part of the country was henceforth known as Galatia. Strabo mentions that the great cities of ancient Phrygia were in his time either deserted or marked by mere villages. The great city over the tomb of Midas has remained uninhabited down to the present day. About 5 m. west of it, near the modern Kumbet, stood Metropolis, a bishopric in the Byzantine time, but never mentioned under the Roman empire.

Alexander the Great placed Phrygia under the command of Antigonus, who retained it when the empire was broken up. When Antigonus was defeated and slain, at the decisive battle of Ipsus, Phrygia came under the sway of Seleucus. As the Pergamanian kings grew powerful, and at last confined the Gauls in eastern Phrygia, the western half of the country was incorporated in the kingdom of Pergamum. Under the Roman empire Phrygia had no political existence under a separate government, but formed part of the vast province of Asia. In autumn 85 B.C. the pacification of the province was completed by Sulla, and throughout the imperial time it was common for the Phrygians to date from this era. The imperial rule was highly favourable to the spread of Hellenistic civilization, which under the Greek kings had affected only a few of the great cities, leaving the mass of the country purely Phrygian. A good deal of local self-government was permitted; the cities struck their own bronze coins, inscribed on them the names of their own magistrates, and probably administered their own laws in matters purely local. The western part of the country was pervaded by Graeco-Roman civilization very much sooner than the central, and in the country districts the Phrygian language continued in common use at least as late as the 3rd century after Christ.

When the Roman empire was reorganized by Diocletian at the end of the 3rd century Phrygia was divided into two provinces, distinguished at first as Prima and Secunda, or Great and Little, for which the names Pacatiana and Salutaris soon came into general use. Pacatiana covered the western half, which had long been completely pervaded by Graeco-Roman manners, and Salutaris the eastern, in which the native manners and language were still not extinct. Each province was governed by a praeses or praefectus about A.D. 412, but shortly after this date an officer of consular rank was sent to each province (Hieroecles, Syned.). About 535 Justinian made some changes in the provincial administration: the governor of Pacatiana was henceforth a comes, while Salutaris was still ruled by a consularis. When the provinces of the Eastern empire were reorganized and divided into themata the two Phrygias were broken up between the Anatolic, Opsician and Thracian themes, and the name Phrygia finally disappeared. Almost the whole of Byzantine Phrygia is now included in the vilayet of Brusa, with the exception of a small part of Parorius and the district about Themisium (Karayuk Bazar) and Ceretapa (Kayadibi), which belong to the vilayet of Konia, and the district of Laodicea and Hierapolis, which belongs to Aydın. The principal modern cities are Kütahya (Cotyaeum), Eskişehir (Dorylaeum), Afyon Karahissar (near Prynneusae), and Uşak (Tranjopolis).

It is impossible to say anything definite about the boundaries of Phrygia before the 5th century. Under the Persians Great Phrygia extended on the east to the Halys and the Salt Desert; Xenophon (Anab. i. 2, 19) includes Iconium on the south-east within the province, whereas Strabo makes Tityraeum the boundary in this direction. The southern frontier is unknown: the language of Livy (xlviii. 19) implies that the southern Metropolis (in the Tchul Ova) belonged to Pisidia; but Strabo (p. 629) includes it in Phrygia. Celaenae, beside the later city of Apamea (Dineir), and the entire valley of the Lycus, were Phrygian. The Maecander above its junction with the Lycus formed for a little way the boundary between Phrygia and Lydia. The great plateau now called the Banaz Ova was entirely or in great part Phrygian. Mt Dindymus (Murad Dagh) marked the contact of Phrygia and Lydia, and the entire valley of the Tembrogus or Tembris (Persuk Su) was certainly included in Phrygia. The boundaries of the two Byzantine Phrygias were not always the same.

Taking Hierocles as authority, the extent of the two provinces at the beginning of the 6th century will be readily gathered from the accompanying list, in which those towns which coined money under the Roman empire are italicized and the name of the nearest modern village is appended.

I. PACATINA.—(1) Laodicea (Eski Hissar); (2) Hierapolis (Pambuk Kaleisi); (3) Mosyna (Gevze); (4) Motelopoli, only in Notitiæ.

1 This liberty was not granted to the cities of any other province in Anatolia.

2 A number of inscriptions in a language presumably Phrygian have been discovered in the centre and east of the country; they belong generally to the end of the 2nd and to the 3rd century.
PHRYGIA

Episcopal (Measure); (5) Attuada (Assar); (6) Trapesopolis (Bolo S., from Serai Kebil); (7) Colossae (near Chonas); (8) Cretapia Dioecesis (Kayadib); (9) Themistia (Kayrek Bazar); (10) Tacina (Yar- shah); (11) Kavak, in Daz Kizi; (12) Dignopolis (Orta Kizi); (13) Anastasopolis (village near Uch Kuyular); (14) Attanassos (Eski Aidan); (15) Lunda (Eski Seid); (16) Felse (Kayrayashlar); (17) Exemna (Ishkeli); (18) Sital Mende (renamed Papatli); (19) Pupuza (Duman or Suretli); (20) Bse (Bourgas); (21) Sebastian (Sebesta); (22) Cibyra (village near Tchorgia); (23) Amontia (Ahat Kebil); (24) Afla (Kirka); (25) Sichassos (Oktar); (26) Dileo (Dola); (27) Aristums (Kara Eren, in Sitchani Ova); (28) Hofranus (Gundekh Yeke); (29) Apia (Aliha); (30) Cotaemus (Kutashi); (31) Pithos (Pithos Amel); (32) Cardo (Vediz); (33) Anayro (Kilisse Kebil); (34) Sichtig (Sogut); (35) Haplotopis Temnotesly (Usak); (36) Trajanopolis Grimembrana (Giaour Eren, near Orta Kizi); (37) Blaudus (Suleimanli); (38) Kiti (Kecil); (39) Hieropolis (Kuch Hassar); (40) Orovus (Tchor Hassar); (41) Svedantes (Kazar); (42) Brusius (Kara Sandyk); (43) Beusus (Aghzi Kaza); (44) Augustus, formerly Anastasia (Surmenich); (45) Siddubinda (Bajik Hassar); (46) Lydus (Man). Symmata, in Cassabia; (47) Pyrmnus (Selun); (48) Ipsus, afterwards Julia Nova Seciles (31); (49) Bashi (Bolavoudun); (50) Dogmstes (Istica Kara Hassar); (51) Metropolis (Kumbet), including Conni (B. Tchorgia) and Ambusius (Ambanaz); (52) Ktesias (village near Kasabian); (53) Noclote (Sedi Ghaiz); (54) Doryphoros (Doryphoros Kebil); (55) Donktes (Kalek); (56) Aulora (in Dombasi Ova); (57) Amansus (unknown, perhaps corrupt: it should include Kinnabari near Genel); (58) Pratium (Pratium Kebil). In later times the important fortress and bishopric of Acreomus was founded on the site of the present Afam Kara Hassar.

Besides these, certain cities beyond the bounds of the Byzantine Phrygia belonged under the Roman empire to the province of Asia and are included in the list in Eusebius' reports. Phylleimhem (Ak Shehr), Hadrianoplis; (2) in Byzantine Galatia, Amorium (Assar near Hamza Hadji), Orcistus (Alkeli or Alekian), Trocnada or Trocnada (Kaimaz); (3) in Byzantine Lybia, Cybup (Cybup). Phrygia contains several well-marked geographical districts. (1) Paroos, the long, level, elevated valley stretching north-west to south-east between the Sultan Dagh and the Emir Dagh from a height of 3,000 feet (18); its waters collect within the valley, in three lakes, which probably formed the Phrygian lake in the Axylon and through them the Sangarius. (2) AXYLON, the vast treeless plains on the upper Sangarius; there burst forth the streams which water the great valleys of the spring fed springs, the Sakaria fountains (Strabo p. 543). Ilie Bashi, Bunar Bashi, Kayka Bashi, Yurcu Bashi, &c., which feed the Sangarius. Great part of the Axylon was assigned to Galatia. (3) The rest of Phrygia is mountainous (except the great plateau, Banz Ova), consisting of hill-country intersected by rivers, each of which flows from a fertile vale through a rocky breadth. The northern half is drained by rivers which run to the Black Sea; of these the eastern ones, Porsuk Su (Tembis or Tembres), Ereklid Ova, (Parthenius), Bardakiachi Tchali (Xerabates), and Bayat Tchali (Abimbino), with the western, Taushanty Tchali (Rhynados) and Simav Tchali (Macestus), &c., which flow into the Propontis. The Hermus drains a small district included in the Byzantine Phrygia, but in earlier times assigned to Lydia and Mygdonia. Sudochia and Arcadian Phrygia is drained by the Macander with its tributaries, Sandyyk Tchali (Glaucus), Banaz Tchali, Kopii Su (Hippurios), and Tchuruk Su (Lyccus), moreover, some upland plains on the south, especially the Doomane (Uculora), communicate underground channels with the Macander. Finally, the Karayuk Ova in the extreme west drains through the Kazans, a tributary of the Indus, to the Lycean Sea. Phrygia Paroos and all the river-valleys are exceedingly watered by the great occupation of the ancient inhabitants; according to the myth, Gordius was killed and devoured by the plough of the throne. The high-lying plains and parts of the vast Axylon furnish good pasturage, which formerly nourished countless flocks of sheep, and many fine horses from Phrygia. Grapes, which still grow abundantly, were cultivated in ancient times. Other fruits are rare, except in a few small districts. Figs cannot grow in the country, and the ancient Phrygians were either erroneous or due to a loose use of the term Phrygian. The land is not very fertile, owing to the dislocation of the marble of Synnade, or more correctly of Docimius, was largely used by the Romans. Copper and quicksilver were mined in the Zizinda district. Throughout the Phrygian country, the landscape has beauty and it is a diversified melocharacter; the deep valleys are rarely abunda. or more correctly of Docimius, was largely used by the Romans. Copper and quicksilver were mined in the Zizinda district. Throughout the Phrygian country, the landscape has beauty and it is a diversified melocharacter; the deep valleys are rarely abunda.

1 Nos. 1-5 were called the Phrygian “Pentapolis.”

2 This district was according to the Greek view part of Myasia.

3 In Strabo, p. 577, διδοις must be wrong; ἐδιδότως is true to fact, and is probably the right reading. Olives cannot now grow on these uplands, which are over 3,000 ft. above sea-level.

4 The influence which was exerted on Greek music and lyric poetry by the Phrygian music was great; see Marsyas; Olympus.

5 Owing to the scantiness of published material about Phrygian frequent reference has been made in this article to unpublished
PHRYNE—PHTHALIC ACIDS

monuments. Besides the works already quoted of Abel and Perrot, see Ritter's "Kleinasien," in his Erkundung von Asien; Leake, Asia Minor (1824); Kiepert appendix to Franz, Fünf Inschr. u. fünf Schriften (1865); Haase, in Ersch and Gruber's Bäckefotb. art. "Phrygien"; Hamilton, Travels in Asia Minor (1842); his "Reisebericht," in the Ber. Monatsh. (1879); Teixeira, A. de, Anise amurensis (1862); Steuart, Ancient Monuments of Lydia and Phrygia, besides the geographical treatises of Cramer, Viven St Martin, Forberg, &c., numerous articles by recent travellers.

Some of the titles of his plays, Danaides, Actaeon, Alectias, Tantalus, show that he treated mythological as well as contemporary subjects. He introduced a separate actor as distinct from the leader of the chorus, and thus laid the foundation of dialogue. But in his plays, as in the early tragedies generally, the dramatic element was subordinate to the lyric element as represented by the chorus and the dance. According to Suidas, Phrynichus first introduced female characters on the stage (played by men in masks), and made special use of the trochaic tetractemeter.

The name of the person treated is Mnesarete, but owing to her complicated history, she was born at Thespis in Boeotia, but seems to have lived at Athens. She acquired so much wealth by her extraordinary beauty that she offered to rebuild the walls of Thebes. This may have been destroyed by Alexander the Great (336), on condition that the words "Destroyed by Alexander, restored by Phryne the courtesan," were inscribed upon them. On the occasion of a festival of Poseidon at Eleusis she laid aside her garments, let down her hair, and stepped into the sea in the sight of the people, thus suggesting to the painter Apelles his great picture of Aphrodite Anadyomene, for which Phryne sat as model. She was also (according to some) the model for the statue of the Cnidian Aphrodite by Praxiteles. When accused of profaning the Eleusinian mysteries, she was defended by the orator Hypereides, one of her lovers. When it seemed as if the verdict would be unfavourable, he rent her robe and displayed her lovely bosom, which so moved her judges that they acquitted her. According to others, she herself thus displayed her charms. She is said to have made an attempt at the virtue of the philosophers Xenocrates. A statue of Phryne, the work of Praxiteles, was placed in a temple at Thebes by the side of a statue of Aphrodite by the same artist.

Some of the titles of his plays, Danaides, Actaeon, Alectias, Tantalus, show that he treated mythological as well as contemporary subjects. He introduced a separate actor as distinct from the leader of the chorus, and thus laid the foundation of dialogue. But in his plays, as in the early tragedies generally, the dramatic element was subordinate to the lyric element as represented by the chorus and the dance. According to Suidas, Phrynichus first introduced female characters on the stage (played by men in masks), and made special use of the trochaic tetractemeter.

In Fragments in A. Nauck, Tragicorum graecorum fragmenta (1887).

2. A poet of the Old Attic comedy and a contemporary of Aristophanes. His first comedy was exhibited in 429 B.C. He composed ten plays, of which the Solitary (Morophoros) was exhibited in 441 along with the Birds of Aristophanes and gained the third prize. The Muses carried off the second prize in 405, Aristophanes being first with the Frogs, in which he accuses Phryne of employing vulgar tricks to raise a laugh, of plagiarism and bad versification.

Fragments in T. Kock, Commemorium atticorum fragmenta (1880).

3. Phrynichus Arabus, a grammarian of Bithynia, lived in the 2nd century A.D. According to Suidas he was the author of (1) an Atticis, or On Attic Words, in two books; (2) Thēkēs sunagōgē, a collection of subjects for discussion; (3) Σωφροσυν ταραξη, or Sophistical Equipment, in forty-seven (or seventy-four) books. As models of Attic style Phrynichus assigned the highest place to Plato, Demosthenes and Aeschines the Socratic. The work was learned, but prolix and garrulous.

A fragment contained in a Paris MS. was published by B. de Montfaucon, and by I. Bekker in his Anecdota graeca (1814). Another work of Phrynichus, not mentioned by Photius, but perhaps identical with the Atticis mentioned by Suidas, the Selection (Ελεξώγραφα) of Attic Words and Phrases, is extant. It is dedicated to Conelinius, a man of literary tastes, and one of the imperial secretaries, who had invited the author to undertake the work. It is a collection of current words and forms which deviated from the Old Attic standard, or the true Attic equivalents being given side by side. The work is a lexicon anti-barbarum, and is interesting as illustrating the changes through which the Greek language had passed between the 4th century B.C. and the 2nd century A.D.

Editions of the Ελεξώγραφα, with valuable notes, have been published by C. A. Lobek (1820) and W. G. Rutherford (1881); Lobek devotes his attention chiefly to the later, Rutherford to the earlier usages noticed by Phrynichus. See also J. Breus, De Phrynico Atticis (1895).

4. An Athenian general in the Peloponnesian War. He took a leading part in establishing the oligarchy of the Four Hundred at Athens in 411 B.C., and was assassinated in the same year (Thucydides viii.).

PHTHALAZONES (benzo-orthoazolines or benzopyrazidines), in organic chemistry a group of heterocyclic compounds containing the ring complex shown in formula I. They are isomeric with the cinnolines (q.v.). The parent substance of the group, phthalazine, C6H4N, is best obtained from the condensation of o-tetramorphone with hydrazine (D. Gabriel, Ber., 1893, 26, p. 2210), or by the reduction of chlorophthalazine with phosphorus and hydrochloric acid (Ber., 1897, 60, p. 102), or by the reduction of chlorophthalazine with phosphorus and hydrochloric acid (Ber., 1897, 60, p. 102). It possesses basic properties and forms addition products with a number of chlorides. On oxidation with alkaline potassium permanganate it yields pyridazine dicarboxylic acid. Zinc and hydrochloric acid decompose it with formation of orthoxylylene diamine.

The keto-hydro derivative phthalaldehyde, C6H4O2N, (formula II.), is obtained by condensing hydrazine with orthophthalaldehyide acid. On treatment with phosphoric oxichloride it yields a chlorophthalazine which with zinc and hydrochloric acid gives isophthalazine, C6H4N, and with tin and hydrochloric acid phthalimidine, C6H4ON, the second nitrogen atom being eliminated as ammonia.

I. Phthalazine. II. Phthalaldehyde.

PHTHALIC ACIDS, or BENZENE DICARBOXYLIC ACIDS, C6H4(CO2)2. There are three isomers: (1) ortho, or phthalic acid; (2) meta, or isophthalic acid; (3) para, or terephthalic acid.

Phthalic acid was obtained by Laurent in 1836 by oxidizing naphthalene tetrachloride, and, believing it to be a naphthalene derivative, he named it naphthalic acid; Marignac restated its formula and showed Laurent's supposition to be incorrect, upon which Laurent gave it its present name. It is manufactured by oxidizing naphthalene tetrachloride (prepared from naphthalene, potassium, chlorate and hydrochloric acid) with nitric acid, or, better, by oxidizing the hydrocarbon with fuming sulphuric acid, using mercury or mercuric sulphate as a catalyst (German pat. 91, 202). It also results on the oxidation of ortho-
PTHESIS—PHYLITE

didervatives of benzene. It forms white crystals, melting at 213° with decomposition into water and phthalic anhydride; the latter forms long white needles, melting at 188° and boiling at 284°. Heated with an excess of lime it gives benzene; calcium benzoate results when calcium phthalate is heated with one molecule of lime to 330°-350°. The acid (and anhydride) are largely used in the colour industry (see FLUORESCIN; PHENOL-PHTHALEIN).

Phthalyl chloride, CH₂(COCI) or CH₂(CCl₃)(CO)O, formed by heating the anhydride with phosphorus chloride, is an oil which solidifies at 0° and boils at 275°. In some reactions it behaves as having the first formula, in others as having the second. Phthalyl chloride with phosphorus pentachloride gives two phthalyl mono-tetrachlorides, one melting at 88° and the other at 47°. They cannot be changed into one another, and have been given the formulae CH₂(COCI)₂(COCI) and CH₂(CCl₃)CH₂O. Phthalimide, CH₂(CO)₂NH, is formed by heating phthalic anhydride or chloride in ammonia gas or by molecular rearrangement of ortho-cyananbenzoic acid. It forms N-metallic and alkyl salts. Bromine and potash give antranilic acid, CH(NH₃)CO(OH). (See INDIGO.

Isophthalic acid is obtained by oxidizing meta-xylene with chromic acid, or by fusing potassium meta-sulphobenzoate, or meta-bromobenzoate with potassium formate (terephthalic acid is also formed in the last case). It melts above 300°, and dissolves in phosphoric acid and cold water and in 460° of boiling. The barium salt (+6H₂O) is very soluble (a distinction between phthalic and terephthalic acids). Usitac acid, 5-methyl isophthalic acid, is obtained by oxidizing mesitylene or by condensing pyrocarboxylic acid with baryta water.

Terephthalic acid, formed by oxidizing para-didervatives of benzene, or best by oxidizing caraway oil, a mixture of cymene and cuminol, with chromic acid, as almost insoluble in water, alcohol and ether; it sublimes without melting when heated.

For the reduced phthalic acids see POLYMETHYLENES.

PHESIS (Gr. φθήσις "wastening"), a term formerly applied (like "Consumption") to the disease of the lung now known as Tuberculosis (q.v.).

PHYLACTERY (φυλακτήρ), a Greek word meaning "guard" (sc. against misfortune), i.e. an amulet. It is applied in the New Testament to the teftin or "prayer-thongs" worn by orthodox Jews daily at morning-prayer (whether at home or in the synagogue). The title employed in Hebrew, teftin, seems really to be derived from an Aramaic term meaning "attachments," "ornaments;" it corresponds to the Biblical Hebrew word rendered "frontlets" (tadot). The teftin or phylactery are worn, one on the left arm (the "hand-teftila"), and the other on the head (the "head-teftila"). In each case the leather thongs support a small satchel which is fastened to the arm by a thong which passes through the thongs, and to the head respectively, and contains certain passages of the Law written (in Hebrew) on parchment, viz. Exod. xii. 1-10 and ii. 13-16; Deut. vi. 4-9 and xi. 13-21. The custom of wearing phylacteries seems to have been derived in the first instance from the Pharisees. By the Sadducees and the generality of the people in the time of Christ it seems not to have been practised. Later it became—not without protest—one of the badges of orthodox Judaism. It is significant that the custom is entirely unknown to the Samaritan community.

The phylacteries, together with the "fringe" (tsistik) and door-post symbol (mezuzah)—which latter consists of a piece of parchment, containing the Hebrew text of Deut. vi. 4-9 and xi. 13-21 enclosed in a glass or metal tube, and fixed upon the right upper post of the door of each dwelling-room in a house—form the three sets of visible signs by which the Israelite is constantly reminded of his duty to God (cf. Num. xv. 39-40; Deut. vi. 9; xi. 20). The "fringe" (or "tassels") was originally attached to the common outer garment—a large square wrap—the loose end of which hung over the left shoulder. This garment with tassels is mentioned in the New Testament (cf. Matt. ix. 20; xiv. 36; xxiii. 5 and parallels). Among modern Jews it has survived in two forms: (1) the fringed praying shawl called talith worn by every male orthodox Jew at the synagogue morning service; and (2) an under-garment, shaped like a chest-protector, one part covering the chest, the other the back, which is worn continuously by male orthodox Jews. It is called Arba Kanfot (i.e. "Four Corners," Deut. xxii. 12) or "little Talith," "heutigen," of course, "fringed." Both phylactery and mezuzah were supposed to keep off hurtful demons (Targ. on Cant. viii. 3).

See Surenhusius, Mischna, i. 9 sq.; and Bodenschutz, Kirch. Ver. d. heutigen Juden, iv. 9 sq.

PHYLARCHUS, a Greek historian, who flourished during the time of Aratus, the strategus of the Achaean League, in the 3rd century B.C. His birthplace is variously given as Athens, Naucratis, or Sicyon. He was probably a native of Naucratis, and subsequently migrated to Athens. He was the author of a history in 28 books, covering the period from the expedition of Pyrrhus king of Epirus to Peloponnesus (272) to the death of the Spartan king Cleomenes (220) after his defeat by Antigonus Doson. Polybius (ii. 56-63) charges him with undue partiality for Cleomenes and unfairness towards Aratus; Plutarch (Aratus, 38), who is of the same opinion, did not hesitate to use him freely in his own biographies of Ages and Cleomenes.

A fragment and part of a monograph in C. W. Müller, Fragmenta historica graecorum, vol. i. (1841) and C. A. F. Brückner (1839); C. Wasmuth, Einleitung in das Studium der alten Geschichte (1875).

PHYLE, a mountain fortress, on a pass leading from Athens to Boeotia and Thebes, and commanding a fine view of the Attic plain. It is situated on the south-west end of Mt Parnes. It is chiefly famous for its occupation by Thrasybulus at the head of the Athenian exiles during the rule of the Thirty Tyrants in 494 B.C. After defending himself from attack, with the help of a snowstorm, he succeeded by a venturesome night march in capturing Muncyia. Close to Phyle is the cliff called Harmo, over which the Pythian lightnings were watched for from Athens.

PHYLITE (Gr. φύλλον, a leaf, probably because they yield leaf-like plates, owing to their fissility), in petrology, a group of rocks which are in practically all cases metamorphosed argillaceous sediments, consisting essentially of quartz, chlorite and muscovite, and possessing a well-marked parallel arrangement or schistosity. They form an intermediate term in the series of altered clays or shaly deposits between clay-slates and mica-schists. The clay-slates have a very similar mineral composition to the phylmites, but are finer grained and are distinguished also by a very much better cleavage. In the phylites also white mica (muscovite or sericite) is more abundant as a rule than in slate, and its crystalline plates are larger; the abundance of mica gives these rocks a glossy sheen on the smooth planes of fissility. Many of the best Welsh slates are rich in small scales of white mica, which polarize brightly between crossed nicols. The Cornish slates are still more micaceous and rather coarser grained, so that they might be called mica-slates or even phylmites.

A microscopical section of a typical phylite shows green chlorite and colourless mica both in irregular plates disposed in parallel order, with a greater or smaller amount of quartz which forms small lenticular grains elongated parallel to the foliation. Grains of iron oxide (magnetite and haematite) and black graphitic dust are very commonly present. The foliation is absent in essence, but some phylitles are characterized by the development of small rounded grains of albite, often in considerable numbers. The minute needles of rutile, so often seen in clay-slates, are not often met with in phylites, but this mineral forms small prisms which may be intergrown with black magnetite; at other times it occurs as networks of sagenite. Other phylites contain carbonates (usually calcite but sometimes dolomite) in flat or spindle-shaped crystals, which often give evidence that the rock has been subjected to a high temperature. Very often the needles of tourmaline occur, and it is very rare in phylites, though readily overlooked. Garnet occurs sometimes, a good example of garnetiferous phylite being furnished by the whetstones of the Ardenness, in which there are many small crystals of garnet. Hornblende, often in branching feathery crystals, is a less frequent accessory. Some phylites a mineral of the chloroid group makes its appearance; this may be olivine, sidimonde or other varieties of chloroid, and occurs in large sub-hexagonal plates showing complex twinning, and lying across the foliation planes of the rock, so that they seem to have developed after the movements and pressures which gave rise to the foliation had ceased.
The structural variations presented by the phyllices are comparatively few. The most finely crystalline specimens have generally the most perfect parallel arrangement of their constituents. The foliation is generally flat or linear, but in some rocks it is undulose or cramped. From the imperfectness of their cleavage, phyllices are rarely suitable for roofing materials; their softness renders them valueless as road stones, but they are not uncommonly employed as inferior building materials. They are exceedingly common in all parts of the world where metamorphic rocks are found, as in the Scottish Highlands, Cornwall, Anglesey, north-west Ireland, the Ardennes, the Harz Mountains, Saxony, the Alps, Norway, the Appalachians, the Great Lakes district in America, &c. (J. S. F.)

**Phylloxera** (Gr. φυλλοξηρ, leaf, and ἄσης, dry), a genus of insects belonging to the family of Aphidae, or Plant-lice, in the Heteroptera, or Assasin Flies, of the order Hemiptera. It is chiefly known from the causal relation of one of its species to the most serious of vine-diseases. The name was first given in 1834 to a plant-louse which was observed to "dry up the leaves" of oaks in Provence. About twenty-seven species are now known, all characterized by length not exceeding 0.6 of an inch, flat wings, three articulations in the antennae, one or two articulations in the tarsi, with digestes, but without cornicles on the abdomen.

The following full description of the only species which attacks the vine, the *Phylloxera vastatrix*, or grape-louse, is reprinted from the article *Vines* in the 9th edition of this encyclopedia.

"The disease, by means of which an infected spot may be readily recognized, is as follows: The vines are stunted and bear few leaves, and those small ones. When the disease reaches an advanced stage the leaves are discoloured, yellow or reddish, with their edges turned back, and wilt and die, and in their growth and their skin is wrinkled. If the roots are examined numerous fusiform swellings are found upon the smaller rootlets. These are at first yellowish in colour and fleshy; but as they grow older become black and corky, and when exposed to the surface they are a perfectly transparent cork. The roots on which these swellings occur band be examined with a lens, a number of minute insects of a yellow-brown colour are observed; these are the root-forms (radio-colored In remiges) *Phylloxera* are about 8 mm. long, an oval outline and with a swollen body. No distinction between thorax and abdomen can be observed. The head bears small red eyes and a pair of three-jointed antennae, the first two joints being short and thick, the third more elongated, with the end cut off obliquely and slightly hollowed out. Underneath, between the legs, lies the rostrum, which reaches back to the abdomen. The insect is fixed by this rostrum, which is inserted into the root of the vine for the purpose of sucking the sap. The abdomen consists of seven segments, and these as well as the anterior segments bear four rows of small tubercles on their dorsal surface. These root-dwelling insects are females, which lay parthenogenetic eggs. The insect is fixed by its proboscis, but moves its abdomen about the body of the vine, and at any time and by any means, the insect can be removed from its place in the vine, the root of which it has fixed itself. When removed, an empty cavity is left in the side of the vine.

These leaf-candles and abdomen can be observed. The head bears small red eyes and a pair of three-jointed antennae, the first two joints being short and thick, the third more elongated, with the end cut off obliquely and slightly hollowed out. Underneath, between the legs, lies the rostrum, which reaches back to the abdomen. The insect is fixed by this rostrum, which is inserted into the root of the vine for the purpose of sucking the sap. The abdomen consists of seven segments, and these as well as the anterior segments bear four rows of small tubercles on their dorsal surface. These root-dwelling insects are females, which lay parthenogenetic eggs. The insect is fixed by its proboscis, but moves its abdomen about the body of the vine, and at any time and by any means, the insect can be removed from its place in the vine, the root of which it has fixed itself. When removed, an empty cavity is left in the side of the vine.

If the larvae hatch out of the eggs, they are light yellow in colour and in appearance resemble their mother, but with relatively larger appendages. They move actively about for a few days, and then, having selected a convenient place on the young roots, insert their proboscis and become stationary. They moult five times, becoming with each change of skin darker in colour; in about three weeks they become adult and capable of laying parthenogenetic eggs.

In this way the insect increases with appalling rapidity; it has been calculated that a single mother which dies after laying her eggs in March would have over 25,000,000 descendants by October. If, however, the insect were constant with this method of reproduction, the disease could be isolated by surrounding the infected patches with a deep ditch full of some such substance as coal-tar, which would prevent the insects spreading on to the roots of healthy vines. The fertility of the parthenogenetically produced insects would diminish after a certain number of generations had been produced.

As the summer wears on a second form of insect appears amongst the root-dwellers, though hatched from the same eggs as the form described above. These are the nymphs, destined to acquire wings; their body is more slender in outline, and at first they bear well-marked tubercles. After several mouls the rudiments of wings appear, and then the insect creeps up to the surface of the earth, and on to the vine. Here it undergoes its fifth and last moult, and appears as a winged female, capable of reproducing parthenogenetically. The winged form has a slender body with distinct head (fig. 2). The eyes are well developed, with numerous facets; the antennae have three joints, the terminal one shaped like that of the root-dwellers. The wings are transparent, with few nervures, and are well adapted for flight. The anterior pair reaches far beyond the end of the abdomen: the posterior are narrower and not so long. These winged forms are about 1 mm. long. They fly about from July till October, and are always found on the top of the vine, which is sucked up by the rostrum from the leaves or buds. They lay their parthenogenetically produced eggs in the angles of the veins of the leaves, in the buds, or, if the season is already far advanced, in the bark. In very damp or cold weather the insect remains in the ground near the surface, and deposits its eggs there. The eggs are very few in number and of two sizes, small and large (fig. 3, b and c). From the larger a female (fig. 4) is hatched in eight or ten days, and simultaneously, for the first time in the life-history of the *Phylloxera*, a male (fig. 3) appears from the smaller egg. Neither male nor female has wings; the rostrum is replaced by a functionless tube; and there is no alimentary canal. The female is larger than the male and differs from it and the other forms in the last joint of the antennae. The life of these sexual forms lasts but a few days, and is entirely taken up with reproduction. The female is fertilized by the male and three or four days later a single egg—the winter egg—and dies. This egg is laid in the leaves of the barks of the vine, and as it is protectively coloured it is almost impossible to find it. Here the winter eggs remain undeveloped during the cold months; but in the following spring, as a rule in the month of April, they give birth to a female insect without wings, which resembles the root-dwelling forms, but has pointed antennae. These forms are termed the stock-mothers; they creep into the buds of the vine, and, as these develop into the young leaves, insert their proboscis into the upper side. By this means a gall is produced on the under side of the leaf.

**Scheme of the Various Forms of Phylloxera vastatrix.**

A. Root-infesting forms.  
B. Winged forms.  
C. Root-infesting, 3rd generation.  
D. Male.  
E. Winter eggs.  
F. Stock-mother.  
G. Gall-producing.  
H. Root-infesting 2.  
I. Ditto.  

The gall is cup-shaped, and its outer surface is crumpled and covered with small warts and hairs. The opening upon the upper surface
of the leaf is protected by similar structures. Within this gall the stock-mother lives and surrounds herself with numerous parthenogenetically produced eggs—sometimes as many as two hundred in a single gall; these eggs give birth after six or eight days to a numerous progeny (gallulae), some of which form new galls and multiply in the leaves more than five years, while the rest otherwise have been destroyed by the root-dwelling forms already described. The galls and the gall-producing form are much commoner in America than in the Old World.

The particular species of phylloxera which attacks the vine is a native of the United States, probably originating among the wild vines of the Colorado district. It was first observed in 1856 by Asa Fitch (1809-1878), who did not suspect its mischief, and called it *Pemphigus vitis*. It was discovered by Westwood in an English vineyard at Hammersmith; he was ignorant of Fitch's observation, and called it *Perisybria vitisana*. From 1858 to 1863 there were many importations of American vines for grafting purposes to Bordeaux, Roquemaure and other parts of France; England, Ireland, Germany, Portugal, &c. It is practically certain that the deadly phylloxera was imported on these plants. A year or two later certain vine-growers in the South of France began to complain of the new vine-disease. M. Delorme, of Arles, in 1865, appears to have been the first who recognized its novelty and had a presentiment of disaster. The disease steadily spread outwards in concentric circles from its first place of lodgment near Roquemaure. Within two or three years whole departments were infested. In 1866 a second centre of infection made its appearance near Bordeaux. The vine-growers were at their wits' end to account for this new plague, which threatened to be even more costly than the oidium. The completeness of the ruin which threatened them may be illustrated by the statistics for a single commune, that of Graveson, whose average annual production of wine in the years 1865-1866 was about 225,000 gallons. In 1868 this fell to 100,000 gallons. In 1866 to 1868, in 4,000,000 gallons, in 1870 to 8,000,000 gallons, and by 1873 to 11,000,000 gallons.

In 1868 Planchnon proved that the disease was due to a new species of phylloxera, which was invariably found on the roots of the affected vines, and to which he accordingly gave the prophetic name of *Phylloxera vastatrix*. During the next ten years a series of students, of whom only Riley and Balbiani need be mentioned here, worked out the natural history of *Phylloxera vastatrix*, and proved its identity with the American grape-louse. Its devastations rapidly assumed gigantic proportions. In France, where the disease was by far the most prevalent—owing in great part to the obstinacy with which the vine-growers at first refused to take any reasonable precautions against its spread—M. Lalande, president of the chamber of commerce at Bordeaux, in 1888 calculated the direct loss to the country by the phylloxera at 10 milliards (540,000,000), or double the indemnity which had been paid to Germany in 1871.

The phylloxera has made its appearance in almost every vine-growing country in the world. Thus it appeared in Austria-Hungary in 1868; in Italy, in spite of the frantic efforts made—as in other countries—to keep it out by strict legislation against the import of vines, in 1879; in Russia in 1880; in Germany, on the Rhine and Moselle, and in Switzerland in 1872; in Madeira, Spain and Portugal, about the same period. The pest even crossed the oceans, and appeared in Australia, at Geelong, about 1880; it has since twice broken out in Victoria, and has ravaged the vineyards of South Australia and New South Wales. At the Cape, in spite of a long endeavour to prohibit the importation of vines, it appeared about 1884. In 1888 it crossed the Mediterranean to Algeria. There was only one country where its ravages were long unimportant; that was its home in the United States, where the native vines had become, by the operation of natural selection, immune to its attacks. Yet no importation of vines has ever entered there that did not complete them, and in 1890 the phylloxera crossed the Rocky Mountains, and seriously damaged the vineyards of California, where it had previously been unknown.

Three different methods of fighting the pest have been successively adopted. One is to kill the phylloxera itself; another, to destroy it along with the infected vines, and plant fresh and healthy plants; the third, to adapt the secular therapeutics of nature, and to introduce American vines which a long acquaintance with the phylloxera has made immune to its ravages. Insecticides, of which the bisulphide of carbon (CS) and the sulpho-carbonate of potassium (KSCS) remain in use, were injected into the earth to kill the phylloxera on the roots of the vines. These methods were chiefly advocated in vineyards where the phylloxera had become an exceedingly costly and time-consuming evil, and where the labourers were precious money and labour to preserve the old and famous vines: the Château Leoville Poyferré and Clos Vougeot are instances. Some good judges attribute the peculiar and not unpleasing flavour of certain clares of 1888 to means thus adopted to kill the phylloxera. The second plan was largely adopted in Switzerland and on the Rhine, where measures resembling those taken with cattle suspected of anthrax were applied to all diseased vineyards. The third plan, which consists in replanting the affected vineyard with American vines—such as the *Vitis labrusca*, *V. riparia*, *V. rupestris* or *V. monticola*—has proved the most generally successful.

A very good bibliography will be found in *Les Insectes de la vigne*, by Professor Majet of Montpellier (1890), which is the best book on vine science. Reference may also be made to the classic memoirs of Planchnon, culminating in *Les Mœurs de la phylloxera de la vigne* (1877); Dreyfus, *Über Phylloxerinen* (1886); Lichtenstein, *Histoire du phylloxera*; the Rapports annuels à la commission supérieure du phylloxera; and the excellent *Report on Phylloxera* drawn up by the Hon. J. W. Tawerner (Victroria, 1890, No. 68).

(W. E. G. F.)

**PHYSHARMONICA—PHYSIOCRATIC SCHOOL**

PHYSHARMONICA, a keyboard instrument fitted with reeds; a kind of harmonium much used in Germany. The phsyharmonica resembles a small harmonium, but is differentiated from it by having no stops; being without percussion action, it does not speak readily or clearly. As in the harmonium, the bellows are worked by the feet by an alternate movement, which also affords a means of varying the dynamic force of the tone according as more or less energetic pedalling increases or decreases the pressure of the wind supply. The phsyharmonica was invented in 1818 by Anton Häckel of Viennia; in the original instrument the bellows were placed right and left immediately under the shallow wind-chest, and were worked by means of pedals connected by stout wire. A specimen, having a compass of four octaves and a very sweet tone, is preserved in the collection of Paul de Wit, formerly in Leipzig, now transferred to Cologne.

(K. S.)

**PHYSICAL PHENOMENA**, in the terminology of spiritualism and psychical research, molar or molecular phenomena in the physical world not traceable to ordinary causes and referred to the action of spirits or of mediums in abnormal psychical states. Among the phenomena or alleged phenomena are: materialization, levitation or elongation of the medium; passage of matter through matter; alteration of weight in a balance, tying of knots in an endless cord, apports (objects brought from a distance) and movements of objects (telekinesis); the production of writing, imprints of plaster or other objects; raps, voices and other sounds, including music; spirit photographs; lights and perfumes. To these may be added immunity against the effects of fire and the untying of ropes.

Analogous phenomena are found in many parts of the world (see *POLTERGEIST; FIREWALKING*); spectral lights are associated with the tombs of Mahomedan saints, with Buddhist shrines, with religious revivals, with Red Indians and other magicians, &c. The natural phenomena are probably a continuation of the phsyharmonica or phsypharmic phenomena, or phsypharmic phenomena, or phsypharmic phenomena. Levitation is asserted of Australian wizards, the rope-trick of Eskimo angekoks; glyphs and direct writing are found in Mexican and Tibetan cults.

See F. Podmore, Modern Spiritualism; F. W. H. Myers, Human Personality, ii, 506; Journal S. P. R., vi, 309 sq.

**PHYSICOCRATIC SCHOOL**, the name given to a group of French economists and philosophers. The heads of the school were François Quesnay (q.v.) and Jean Claude Marie Vincent, sieur de Gournay (1712-1759). The principles of the school had been put forward in 1755 by R. Cantillon, a French merchant of Irish extraction (*Essai sur la nature du commerce en général*), whose biography W. S. Jevons has elucidated, and whom he regards as the true founder of political economy; but it was in the hands of Quesnay and Gournay that they acquired a systematic form, and became the creed of a united group of thinkers.
and practical men, bent on carrying them into action. The members of the group called themselves les économistes, but it is more convenient, because unambiguous, to designate them by the name physiciens (Gr. φύσις, nature, and σπουδή, to rule), invented by P. S. Dupont de Nemours (1733–1817), who was one of their number. In this name, intended to express the fundamental idea of the school, much more is implied than the subjection of the phenomena of the social, and in particular the economic, world to fixed relations of coexistence and succession. This is the positive doctrine which lies at the bottom of all true science. But the law of nature referred to in the title of the sect was something quite different. The theological dogma which represented all the movements of the universe as directed by divine wisdom and benevolence to the production of the greatest possible sum of happiness had been transformed in the hands of the metaphysicians into the conception of a jus naturae, a harmonious and beneficial code established by the favourite entity of these thinkers, nature, antecedent to human institutions, and furnishing the model to which they should be made to conform.

The general political doctrine is as follows: Society is composed of a number of individuals, all having the same natural rights. If all do not possess (as some members of the negative school maintained) equal capacities, each can at least best understand his own interest, and is led by nature to follow it. The social union is really a contract between these individuals, the object of which is the limitation of the natural freedom of each just so far as it is inconsistent with the rights of the others. Government, though necessary, is a necessary evil; and the governing power appointed by consent should be limited to the amount of interference absolutely required to secure the fulfilment of the contract. In the economic sphere this implies the right of the individual to such natural enjoyments as he can acquire by his labour. That labour, therefore, should be undisturbed and unfettered, and its fruits should be guaranteed to the possessor; in other words, property should be absolute. Each citizen must be allowed to make the most of his labour; and therefore freedom of exchange should be ensured, and competition in the market should be unrestricted, no monopolies or privileges being permitted to exist.

The physiocrats then proceed with the economic analysis as follows: Only those labours are truly “productive” which add to the quantity of raw materials available for the purposes of man; and the real annual addition to the wealth of the community consists of the excess of the mass of agricultural products (including, of course, metals) over their cost of production. On the amount of this produit net depends the well-being of the community and the possibility of its advance in civilization.

The manufacturer merely gives a new form to the materials extracted from the earth; the higher value of the object, after it has passed through his hands, only represents the quantity of provisions and other materials used and consumed in its elaboration. Commerce does nothing more than transfer the wealth already existing from one hand to another; what the trading classes gain thereby is acquired at the cost of the nation, and it is desirable that its amount should be as small as possible. The occupations of the manufacturer and merchant, as well as the liberal professions, and every kind of personal service, are “useful” indeed, but they are “sterile,” drawing their income, not from any fund which they themselves create, but from the superfluous earnings of the agriculturist. The revenue of the state, which must be derived altogether from this net product, ought to be raised in the most direct and simplest way—namely, by a single impost of the nature of a land tax.

The special doctrine relating to the exclusive productiveness of agriculture arose out of a confusion between “value” on the one hand and “matter and energy” on the other. A. Smith and others have shown that the attempt to fix the character of “sterility” on manufacturers and commerce was founded in error. And the proposal of a single impôt territorial falls to the ground with the doctrine on which it was based. But such influence as the school exerted depended little, if at all, on these peculiar tenets, which indeed some of its members did not hold. The effective result of its teaching was mainly destructive. It continued in a more systematic form the efforts in favour of the freedom of industry already begun in England and France. It was to be expected that the reformers should, in the spirit of the negative philosophy, exaggerate the vices of established systems; and there can be no doubt that they condemned too absolutely the economic action of the state, both in principle and in its historic manifestations, and pushed the laissez-faire doctrine beyond its just limits. But this was a necessary incident of their connexion with the revolutionary movement, of which they really formed one wing. In the course of that movement, the primitive social contract, the sovereignty of the people and other dogmas now seen to be untenable, were habitually invoked in the region of politics proper, and had a transitory utility as ready and effective instruments of warfare. And so also in the economic sphere the doctrines of natural rights of buying and selling, of the sufficiency of enlightened selfishness as a guide in mutual dealings, of the certainty that each member of the society will understand and follow his true interests, and of the coincidence of those interests with the public welfare, though they will not bear a dispassionate examination, were temporarily useful as convenient and serviceable weapons for the overthrow of the established order.

These conclusions as to the revolutionary tendencies of the school are not at all affected by the fact that the form of government preferred by Quesnay and some of his chief followers was what they called a legal despotism, which should embrace within itself both the legislative and the executive function. The reason for this preference was that an enlightened central power could more promptly and efficaciously introduce the policy they advocated than an assembly representing divergent opinions and fettered by constitutional checks and limitations.

Turgot used the absolute power of the Crown to carry into effect some of his measures for the liberation of industry, though he ultimately failed to sustain them by the requisite force of character in Louis XVI. But what the physiocratic idea with respect to the normal method of government was appears from Quesnay’s advice to the dauphin, that when he became king he should “do nothing, but let the laws rule,” the laws having been, of course, first brought into conformity with the jus naturae. The partiality of the school for agriculture was in harmony with the sentiment in favour of “nature” and primitive simplicity which then showed itself in so many forms in France, especially in combination with the revolutionary spirit, and of which Rousseau was the most eloquent exponent. The members of the physiocratic group were undoubtedly men of thorough uprightness, and inspired with a sincere desire for the public good, especially for the material and moral elevation of the working classes. Quesnay was physician to Louis XV., and resided in the palace at Versailles; but in the midst of that corrupt court he maintained his integrity, and spoke with manly directness on what he considered to be the truth. And never did any statesman devote himself with greater singleness of purpose or more earnest endeavour to the service of his country than Turgot, who was the principal practical representative of the school.

The physiocratic school never obtained much direct popular influence, even in its native country, though it strongly attracted many of the more gifted and earnest minds. Its members, writing on dry subjects in an austere and often heavy style, did not find acceptance with a public which demanded before all things charm of manner in those who addressed it. The physiocratic tenets, which were in fact partly erroneous, were regarded by many as chimerical, and were ridiculed in the contemporary literature; as, for example, the impôt unique by Voltaire in L’Homme aux quarante écus, which was directed in particular against P. P. Mercier-Larivièvre (1730–1794). It was justly objected to the group that they were too absolute in their view of things; they supposed, as Smith remarks in speaking of Quesnay, that the body politic could thrive only under one precise régime—that, namely, which they recommended—and
PHYSIOGNOMY

thought their doctrines universally and immediately applicable in practice. They did not, as theorists, sufficiently take into account national dispositions or different stages in social development; nor did they, as politicians, adequately estimate the impediments which ignorance, prejudice and interested opposition present to enlightened statesmanship.

The physiocratic system, after guiding in some degree the policy of the Constituent Assembly, and awakening a few echoes here and there in foreign countries, soon ceased to exist as a living power; but the good elements it comprised were not lost to mankind, being incorporated into the more complete construction of Adam Smith.

See the article on Quesnay, with bibliography appended thereto, also the articles on Mirabeau and Turgot. Most French histories contain an account of the school; see especially Tocqueville, L' Ancien régime et la révolution, ch. iii.; Taine, Les Origines de la France contemporaine, vol. i.; R. Stourn, Les Finances de l'ancien régime et de la révolution (1885); Droz, Histoire du règne de Louis XVI.; also, C. Lavergne, L'économie franaçaise du XVIIIe siècle; H. Higgs, The Physiocrats (London, 1897, with authorities).

PHYSIOGNOMY, the English form of the middle Greek ψυχογνωμα, a contraction of the classical ψυχωνομα (from ψυχα, nature, and γνωμα, an interpreter), (1) a term which denotes a supposed science for the "discovery of the disposition of the mind by the lineaments of the body" (Bacon); (2) is also used colloquially as a synonym for the face or outward appearance, being variously spelled by the old writers: fysenome or Physiomen by Lydgate, phisnomie in Udall's translation of Erasmus on Mark iv., physnomie in Bale's English Votaries (i. 2. p. 44), and fysnomie in All's well that ends well, iv. 5 (first folio).

Physiognomy was regarded by those who cultivated it as a twofold science: (1) a mode of discriminating character by the outward appearance; and (2) a method of divination from form and feature. On account of the abuses of the latter aspect of the subject its practice was forbidden by the English law, but the act of parliament 17 George II. c. 5 (1743) all persons pretending to have skill in physiognomy were deemed rogues and vagabonds, and were liable to be publicly whipped, or sent to the house of correction until next sessions. The pursuit thus stigmatized as unlawful is one of great antiquity, and one which in ancient and medieval times had an extensive though now almost forgotten literature. It was very early noticed that the good and evil passions by their continual exercise stamp their impress on the face, and that each particular passion has its own expression. Thus far physiognomy is a branch of physiology. But in its second aspect it touched divination and astrology, of which Galen says that the physiognomical part is the greater, and this aspect of the subject bulked largely in the fanciful literature of the middle ages. There is evidence in the earliest classical literature that physiognomy formed part of the most ancient practical philosophy. Homer was a close observer of expression and of appearance as correlated with the character, as is shown by his description of Thersites and elsewhere. Hippocrates, writing about 450 B.C., expresses his belief in the influence of environment in determining disposition, and in the reaction of these upon feature, a view in which he is supported later by Trogus. Galen, in his work Περὶ τῶν τῶν ὑποκρίσεων, having discussed the nature and immortality of the soul, proceeds in ch. vii. to a brief study of physiognomy (ed. Kuhn iv. 795). In this passage he deprecates current physiognomical speculations, saying that he might criticize them but feared to waste time and become tedious over them. In chapter viii. he quotes with approbation the Hippocratic doctrine referred to above; and

1 The Act 39 Elizabeth c. 4 (1597-1598) declared "all persons favoring to have knowledge of Phisognomy or like fantastical learning," to be "be stripped naked from the middle upwards and openly whipped until his body be bользyed." This was modified by 13 Anne c. 26 (1715), still further by 17 George II. c. 5, which was re-enacted by the Vagrancy Act 1824. This last act only specified the paraphernalia of a practitioner. Galen, Περὶ κακάεων ψυχωρατικά, ed. Kühn xix. 530.

3 A physiognomical study of the Homeric heroes is given by Malalas, Opera quae supersunt, ed. Dindorf, v. 159.

4 Περὶ Δεσυων, δητανων, τόπων (ed. Kühn, i. 547).

5 In a later work, Περὶ κακάεων ψυχωρατικά, he speaks of the advantage of a knowledge of physiognomy to the physician. We learn both from Iamblichus and Porphyry that Pythagoras practised the diagnosis of the characters of candidates for pupilage before admitting them, although he seems to have credited the present physiognomy of the schools, as he rejected Cylo, the Crotonian, on account of his professing these doctrines, and thereby was brought into some trouble. Plato also tells us that Socrates predicted the promotion of Alcibiades from his appearance; and Apuleius speaks of Socrates recognizing the abilities of Plato at first view. On the other hand, it has been recorded by Cicero that a certain physiognomist, Zopyrus, who professed to know the habits and manners of men from their bodies, eyes, face and forehead, characterized Socrates as stupid, sensual and dull (bordus), "in quo Alcibiades cænnum dicitur sustulisse." Alexander Aphrodisiensis adds that, when his disciples laughed at the judgment, Socrates said it was true, for such had been his nature before the study of philosophy had modified it. Zopyrus is also referred to by Maximus Tyrwhit as making his recognitions "intuitu solo.

That one's occupation stamps its impress on the outward appearance was also noticed at an early period. In the curious poem in the Salier papyrus (II.), written about 1800 B.C., Duan, son of Khertu, expatiates on the effects of divers handicrafts on the workmen as compared with the elevating influences of a literary life. Josephus tells us that Caesar detected the pretence of the spurious Alexander by his round hands and surface.

The first systematic treatise which has come down to us is that attributed to Aristotle, in which he devotes six chapters to the consideration of the method of study, the general signs of character, the particular appearances characteristic of the dispositions, of strength and weakness, of genius and stupidity, of timidity, impulse, anger, and their opposites, &c. Then he studies the physiognomy of the sexes, and the characters derived from the different features, and from colour, hair, body, limbs, gait and voice. He compares the varieties of mankind to animals, the male to the lion, the female to the leopard. The general character of the work may be gathered from the following specimen. While discussing noses, he says that those with thick bulbous ends belong to persons who are insensitive, swinish; sharp-tipped belong to the irascible, those easily provoked, like dogs; rounded, large, obtuse noses to the magnanimous, the lion-like; slender hooked noses to the eagle-like, the noble but grasping; round-tipped retroussé noses to the luxurious, like barndoor fowl; noses with a very slight notch at the root belong to the impudent, the crow-like; while snub noses belong to persons of luxurious habits, whom he compares to deer; open nostrils are signs of passion, &c.

The practice of physiognomy is alluded to in many of the Greek classics. Apion speaks of the metempsychosists, who judge by the appearance of the face, and Cleaneles the Stoic says it is

7 Ant. xvii., 12, 2.
8 Authors differ in their views as to its authenticity, but Diogenes Laërtius (v. 22) and Stobaeus (Serm. clxxix.) both believe it to be genuine. The chief difficulty is the reference to a certain sophist, Dionysius, this is probably to be distinguished from the other writings of Aristotle (cf. Anat. pr., ii. c. 30; Hist. anim., i. 8, &c.) sufficient to justify the attribution of the treatise to him. On this, see Franz, Preface, p. vii., p. xxiv., of his Scriptores physiognomiae veteres (Leipzig, 1875).
9 See an interesting passage, "Smelling and Yawning as Signs of Madness," by Professor Ridgeway (Trans. Camb. Phil. Soc., i. 191), which refers to Aristoph. Wasps, 642, with which he compares Flautus, Menandri, 279. Other references exist to physiognomy in Cassiodorus, Iasidus, Meletes and Nemesius, but none of us great importance.
possible to tell habits from the aspect (cf. Eccles, xix. 29, 30). Polemon (c. A.D. 150) compiled a treatise (published 1534, in Latin) on the subject, similar in character to that of Aristotle; but he excels in graphic descriptions of different dispositions, and differs only from Aristotle in some of his animal comparisons. A more important work was written by a converted Jew, Adamantius, about A.D. 415. This is in two books, the first on the expression of the eye, the second on physiognomy in general, mostly Aristotelian in character.

Among the Latin classical authors Juvenal, Suetonius and Pliny in well-known passages refer to the practice of physiognomy, and numerous allusions occur in the works of the Christian Fathers, especially Clement of Alexandria and Origen (for example, the familiar passage in his work against Celsus, i. 33). While the earlier classical physiognomy was chiefly descriptive, the later medieval authors particularly developed the predictive and astrological side, their treatises often digressing into chiro-mancy, onychomancy, clidomancy, podoscopy, spasmomancy, and other branches of prophetic folk-lore and magic.

Along with the medical science of the period the Arabians contributed to the literature of physiognomy: *All* b. Ragel wrote a book on naevi; Rhazes (1040) devoted several sections of a work to it; and Abu 'Abd Allah wrote a special book on naevi in his *De sanitate*, p. 82 (Leiden, 1597). Avicenna also makes some acute physiognomical remarks in his *De animalibus*, which was translated by Michael Scot about 1270. Among medieval writers Albertus Magnus (born 1205) devotes much of the second section of his *De animalibus* to physiognomy; but this chiefly consists of extracts from Aristotle, Polemon and Loxus. He does not enter into the animal comparisons of his predecessors, but occupies himself chiefly with simple descriptive physiognomy as indicative of character; and the same is true of the scattered references in the writings of Duns Scotus and Thomas Aquinas. The famous sage of Balwarie, Michael Scot, while court astrologer to the emperor Frederick II., wrote his treatise *De hominis phisigomia*, much of which is physiological and of curious interest. It was probably composed about 1272, but not printed until 1477. This was the first printed work on the subject. Physiognomy also forms the third part of his work *De secretis naturae*. In 1335 Pietro d'Abano of Padua delivered in Paris a course of lectures on this subject (afterwards edited by Ponderus, 1544), a few years before he was burned for heresy.

The 16th century was rich in publications on physiognomy. The works of the classical authors before mentioned were printed, and other treatises were published by John de Indagine, Cocles, Andreas Corvus, Michael Blondus, Janus Cornaro, Anselm Douciel, Pompeius Ronnseus, Gratatorolus, Lucas Gauricus, Tricassus, Cardanus, Tainsierus, Magnus Hund, Rothman, Johannes Padovanus, and, greatest of all, Giambattista della Porta. The earliest English works were anonymous: *On the Art of Foretelling Future Events by Inspection of the Hand* (1504), and *A Pleasant Introduction to the Art of Chromacie and Physiognomie* (1588). Dr Thomas Hill's work, *The Contemplation of Mankind*, containing a singular Discourse after the *Art of Physiognomy*, published in 1571, is a quaintly written adaptation from the Italian authors of the day. The undated book on moles and naevel by "Merlin Britannicus," after the model of "Ali ibn Ragel, is of about the same date.

The development of a more accurate anatomy in the 17th century seems to have diminished the interest in physiognomy by substituting fact for fiction; and consequently the literature, though as great in quantity, became less valuable in quality. The principal writers of this age were T. Campanella, R. Coclenius, Clement, Timpler, J. E. Gallimard, Moldenarius, Septalius, Saunders, C. Lebrun (a precursor of Charles Bell), Elsholz, de la Bellière, J. Evelyn (in the appendix to *Numisma*), Baldus, Bulwer (in his *Pathomatomyia*), Fuchs, Spontoni, Ghiraldelli, Chiaromonti, A. Ingesneri, Finella, De la Chambre, Zanardus, R. Fludd, and others of less importance.

The 18th century shows a still greater decline of interest in physiognomy. Historians of philosophy, like J. Meursius and Franz, re-edited some of the classical works, and G. Fülleborn reviewed the relation of physiognomy to philosophy. Indeed, the only name worthy of note is that of J. K. Lavater (q.e.). The other authors of this century are Peuschel, Spon, Schutz, Weigel, J. Pernetti, Girtanner, Grohmann, and several anonymous writers, and from the anatomical side G. M. Lancisi, J. Parsons and Peter Camper. The popular style, good illustrations and pious spirit pervading the writings of Lavater have given to them a popularity they little deserved, as there is no system in his work, which chiefly consists of rhetorical comments upon the several portraits. Having a happy knack of estimating character, especially when acquainted with the histories of the persons in question, the good pastor contrived to write a graphic and readable book, but one much inferior to Porta's or Aristotle's as a systematic treatise. The treatises of Nicolai and of Lichtenberg were written to refute his theory. With Lavater the descriptive school of physiognomists may be said to have ended. The writings of most of the later writers are more in harmony with de la Bellière. The few works which have since appeared, before the rise of the physiological school of Sir Charles Bell and Charles Darwin, are undeserving of notice, the development of phrenology having given to pure physiognomy the coup de grâce by taking into itself whatever was likely to live of the older science. The writers of the 19th century are Hörstig, Maas, Rainer, Thoné, A. Stöhr, Sehler, Dr Rubels, Polli, Cardona, Mastriani, Diez, Carus, Piderit, Burgess and P. Graziote.

The physiological school of physiognomy was foreshadowed by Parsons and founded by Sir Charles Bell, whose *Essay on the Anatomy of the Expression*, published in 1806, was the first scientific study of the physical manifestation of emotions in the terms of the muscles which produce these manifestations. In the later editions of this essay the thesis is elaborated with greater detail. Moreau's edition of Lavater, in 1807, was somewhat along the same lines. In 1817 Dr Cross of Glasgow wrote his defence of a scientific physiognomy based on general physiological principles. The experiments of G. B. A. Duchenne (*L'étude de la physiognomie humaine*, Paris, 1862) showed that by the use of electrical stimulations the muscles could be studied and by the aid of photography accurately represented. These observations confirmed by experimental demonstration the hypothetical conclusions of Bell. The machinery of expression having thus been indicated, the connexion of the physical actions and the psychical state was made the subject of speculation by Herbert Spencer (*Psychology*, 1855). These speculations were reduced to a system by Darwin (*Expression of Emotions*, 1872), who formulated and illustrated the following as fundamental physiological principles:

1. Certain complex acts are of direct or indirect service, under certain conditions of the mind, in order to relieve or gratify certain sensations or desires; and whenever the same states of mind are evoked, the same signs will tend to be produced, even when they have ceased to be used. 2. When a directly opposite state of mind is induced to one with which a definite action is correlated, there is a strong and involuntary tendency to perform a reverse action. 3. When the sensorium is strongly excited nerve-force is generated in excess, and is transmitted in definite directions, depending on the connections of nerve-cells and on habit.

The last of these propositions is adversely criticized by P. Mantegazza as a truism, but it may be allowed to stand with the qualification that we are ignorant concerning the nature of the influence called "nerve-force." It follows from these propositions that the expression of emotion is, for the most part, not under control of the will, and that those striped muscles are the most expressive which are the least voluntary. To the foregoing may be added the following three additional propositions, so as to form a more complete expression of a physiological philosophy:

1. Certain muscles concerned in producing these skin-folds be
2. A certain action becomes strengthened by habitual action, and when the diminishes

Footnotes:
1 For Scriptural allusions to physiognomy see Vecchius, *Observations in div. script.* (Naples, 1641). Other classical references are contained in the *Proemium* to the 1593 edition of the works of Baptista Portae.
in elasticity and fulness with advancing age, the wrinkles at right angles to the course of the muscular fibres become permanent. (5) To some extent habitual muscular action of this kind may, by affecting local nutrition, alter the contour of such bones and cartilages as they remain on the surface of the skull. (6) If the spatial relations of position and proneness to action are inherited by children from their parents, it may be that the facility in, and disposition towards, certain forms of expression are in like manner matters of heredity.

Illustrations of these theoretic propositions are to be found in the works of Bell, Duchenne and Darwin, and in the later publications of Theodor Pifer, Mimike und Physiognomie (1886) and Manetazza, Physiognomie and Expression (1890), to which the student may be referred for further information.

For information on artistic anatomy as applied to physiognomy see the writings of the sixty-two authors by Ludwig Choullant, Geschichten und Bildhauerei der anatomischen Abbildung, etc. (Leipzig, 1852), and the works of the authors enumerated above, especially those of Aristotle, Franz, Porta, Carand, Corvis and Balzer. For physiognomy of disease, besides the usual medical handbooks, see Carpentier, Études sur l'expression de la face dans les maladies (Paris, 1850); Manetazza, Physiology of Pain (1893), and Poll, Saggio di fissognome e patognome (1837). For ethnological physiognomy, see amongst others authors Grataroli, and amongst modern writers the cited in various textbooks on anthropology, especially Schadow, Physiognomisches nationales (1835) and Park Harrison, Journ. Anthropol. Inst. (1883). The study of the physical characteristics of criminals has been made by Dr. Sir Henry M. Park, The Great Criminal (1865); Ferri, L'omicidio (1895); von Baer, Der Verbrecher (1893); Laurent, Les Habilites des prisons (1890); and Havelock Ellis, The Criminal (1901). (A.M.)

PHYSIOLÓGUS, the title usually given to a collection of some fifty Christian allegories much read in the middle ages, and still existing in several forms and in about a dozen Eastern and Western languages. As nearly all its imagery is taken from the animal kingdom, it is commonly referred to as "the Bestiary." Gnostics, however, by the evidence of later traditions, hardly a doubt about the time and general circumstances of its origin. Christian teachers, especially those who had a leaning towards Gnostic speculation, took an interest in natural history, partly because of certain passages of Scripture that they wanted to explain, and partly on account of the divine revelation in the book of nature, of which also it was man's sacred duty to take proper advantage. Both lines of study were readily combined by applying to the interpretation of descriptions of natural objects the allegorical method adopted for the interpretation of Biblical texts.

Now the early Christian centuries were anything but a period of scientific research. Rhetorical accomplishments were considered to be the chief object of a liberal education, and to this end every kind of learning was made subservient. Instead of reading Aristotle and other naturalists, people went for information to commonplace books like those of Aelian, in which scraps of folk-lore, travelers' tales and fragments of misapplied science were set forth in an elegant style. To such writers were not in the least prepared to question the worth of the marvellous descriptions of creatures that were current in the schools on the faith of authorities vaguely known as "the history of animals," "the naturalists," and "the naturalist" in the singular number (φυσιολόγος). So they took their notions of strange beasts and other marvels of the visible world on trust and did their best to make them available for religious instruction. In some measure we find this practice adopted by more than one of the Fathers, but it was the Alexandrian school, with its pronounced taste for symbolism, that made the most of it. Clement himself had declared that natural lore, as taught in the course of higher Christian education according to the canon of truth, ought to proceed from "cosmogony" to "the theological idea," and even in the little that is left of the works of Origen we have two instances of the proceeding in question.

Nevertheless, the Physiologus does not suffice to stamp the work as a series of extracts from Alexandrian writings, as parallels of the same kind can be adduced from Epiphanius (loc. cit.) and Epaenetus Syrus (Opp. Syr. ii. 17, 130). Father Cahier would even trace the book to Tattiana, and it is true that that heresarch mentions a writing of his own upon animals. Still, the context in which the quotation occurs makes it evident that the subject-matter was not the nature of particular species nor the spiritual lessons to be drawn therefrom, but rather the place occupied by animal beings in the system of creation. On the other hand, the opinion of Cardinal Pitra, who referred the Physiologus to the more orthodox though somewhat peculiar teaching of the Alexandrians, is fully borne out by a close examination of the irregularities of doctrine pointed out in the Physiologus by Cahier, all of which are to be met with in Origen. The technical words by which the process of allegorizing is designated in the Physiologus, like ἐναπώιος, θεορά, ἰνεργοτός, ἀλληγορα, are familiar to the students of Alexandrian exegesis. It has, moreover, been remarked that almost all the animals mentioned were at home in the Egypt of those days, or at least, like the elephant, were to be seen there sometimes, whereas the structure of the hedgehog, for instance, is explained by a reference to the sea-porcine, a fish known to fish-buyers on the Mediterranean. The fables of the phoenix and of the conduct of the wild ass and the ape at the time of the equinox owe their origin to astronomical symbols belonging to the Nile country. In both chapters an Egyptian month is named, and elsewhere the antelope bears its Coptic name of "anthelos.'

That the substance of the Physiologus was borrowed from commentaries on Scripture is confirmed by many of the sections opening with a text, followed up by some such formula as "but the Physiologus says." When zoological records failed, Epypto-Hellenic ingenuity was never at a loss for a fanciful invention distilled from the text itself, but which to succeeding copyists appeared as part of the teaching of the original Physiologus. As a typical instance we may take the chapter on the ant-lion—not the insect, but an imaginary creature suggested by Job, iv. 14. The exceptional Hebrew for a lion (leyakh), appeared to the Septuagint translators to call for a special rendering, and as there was said to exist on the Arabian coast a lion-like animal called "myrmex" (see Strabo xvi. 774; Aelian, N. A., vii. 47) they ventured to give the compound noun "myrmekoleon." After so many years the commentators had lost the key to this unusual term, and only knew that in common Greek "myrmex" meant an ant. So the text "the myrmekoleon hath perished for that he had no nourishment" set them pondering, and others reproduced their meditations, with the following result: "The Physiologus relates about the ant-lion: his father hath the shape of a lion, his mother that of an ant; the father liveth upon flesh, and the mother upon herbs. And these bring forth the ant-lion, a compound of both, and in part like to either, for his fore part is that of a lion, and his hind part like that of an ant. Being thus composed, he is neither able to eat flesh like his father, nor herbs like his mother; therefore he lieth without nourishment." At a later period, when the Church had learnt to look with suspicion upon devotional books likely to provoke the scoffing of some and lead others into heresy, a work of this kind could hardly meet with her approval. A synod of Pope Gelasius, held in 406, passed censure, among others, on the "Libri Physiologus, qui ab haereticis conscriptus est et B. Ambrosii nomine signatus, apocryphus," and evidence has even been offered that a similar sentence was pronounced a century before. Still, in spite of such measures, the Physiologus, like the Church History of Eusebius or the Pastor of Hermas, continued to be read with general interest, and even Gregory the Great did not disdain to allude to it on occasion. Yet the Oriental versions, which had certainly nothing to do with the Church of Rome, show that there was no systematic revision made according to the Catholic Church.
standard of doctrine. The book remained essentially the same, albeit great liberties were taken with its details and outward form. There must have been many imperfect copies in circulation, from which people transcribed such sections as they found or chose, and afterwards completed their MS. as occasion served. Some even rearranged the contents according to the alphabet or to zoological affinity. So little was the collection considered as a literary work with a definite text that every one assumed a right to abridge or enlarge, to insert ideas of his own, or fresh scriptural quotations; nor were the scribes and translators by any means scrupulous about the names of natural objects, and even the passages from Holy Writ. Physiologus had been abandoned by scholars, and left to take its chance among the tales and traditions of the uneducated mass. Nevertheless, or rather for this very reason, its symbols found their way into the rising literature of the vulgar tongues, and helped to quicken the fancy of the artists employed upon church buildings and furniture.

The history of the Physiologus has become entwined from the beginning with that of the commentaries on the account of creation in Genesis. The principal production of this kind in our possession is the Hexaemerons of Basil, which contains several passages very like those of the Physiologus. For instance, in the seventh homily the fable of the nuptials of the viper and the conger, known already to Aelian and Oppian, and proceeding from a curious misreading of Aristotle (Hist. An. v. 4, 540 b, Bk. k.), serves to point more than one moral. Notwithstanding the difference in theology, passages of this kind could not but be welcome to the admirers of the Alexandrian allegories. In fact a medley from both Basil and the Physiologus exists under the title of the Hexaemeron of Eustathius; some copies of the first bear as a title Ἱερός φωτολογίας, and in a Milan MS. the "morals" of the Physiologus are ascribed to Basil. The Leyden Syriac is supplemented with literal extracts from the latter, and the whole is presented as his work. Other copies give the names of Gregory Theologus, Epiphanius, Chrysostom and Isidore.

As far as can be judged, the emblems of the original Physiologus were the following: (1) the lion (footprints rubbed out with a flag); (2) the serpent (the other of his tail); (3) the chameleon (Deut. xiv. 16; presages recovery or death of patients); (4) the pelican (recalls its young to life by its own blood); (5) the owl (or nyktorkas; loves darkness and solitude); (6) the eagle (renews its life by sunlight and bathing in a fountain); (7) the phoenix (revives from fire); (8) the hoopoe (redeems its parents from the ill of old age); (9) the wild ass (suffers no male beast besides itself); (10) the vipers (born at the cost of both its parents’ death); (11) the serpent (sheds its skin; puts aside its venom before drinking); (12) the star (or celestial body; prevents stored grain from germinating; distinguishes wheat from barley on the stalk); (13) the sirens and centaurs (Isa. xl1. 22, 23; compound creatures); (14) the hedgehog (pricks grapes upon its quills); (15) the fox (catches birds by simulating death); (16) the panther (spotted skin; enmity to the dragon; seven days after meals; allure its prey by sweet sound); (17) the sea-tortoise (or aspidochelone; mistaken by sailors for an island); (18) the partridge (hatches eggs of other birds); (19) the vulture (assisted in birth by a stone with loose kernel); (20) the ant-lion (able neither to take the one food nor to digest the other); (21) the weasel (conceives by the mouth and brings forth by the ear); (22) the unicorn (caught only by a virgin); (23) the beaver (gives up its testes when pursued); (24) the hyena (a hermaphrodite); (25) the otter (enhydris; enters the crocodile’s mouth to kill it); (26) the ichneumon (covers itself with mud to kill the dragon; another version of No. 23); (27) the crow (takes but one consort in its life); (28) the turtle-dove (same nature as No. 27); (29) the frog (either living on land and killed by rain, or in the water without ever seeing the sun); (30) the stag (destroys its enemy the serpent); (31) the salamander (quenches fire); (32) the diamond (powerful against all danger); (33) the swallow (brings forth but once; mistreating of Aristotle, Hist. An. v. 13); (34) the tree (called perdicina Caius). Besides the Caius, the Physiologus was especially extolled by its shadow; (35) the pigeons (of several colours; led by one of them, which is of a purple or golden colour); (36) the antelope (or hydropius; caught by its horns in the thicket); (37) the fire-flies (of two sexes; combine to produce fire); (38) the magnet (adheres to iron); (39) the sawfish (sails in company with ships); (40) the ibis (flies only along the shore); (41) the ibex (decrives a hunter from afar); (42) the diamond again (read “carefully”; found only by night); (43) the elephant (conceives after partaking of mandrake; brings forth in the water; the young protected from the serpent by the father; when fallen is lifted up only by a certain small individual of its own kind); (44) the agate (employed in pearl-fishing); (45) the wild ass and ape (mark the equinox); (46) the Indian stone (relieves patients of the dropsy); (47) the heron (touches no dead body, and keeps to one dwelling-place); (48) the sycamore (or wild fig; grubs living inside the fruit and coming out); (49) the ostrich (devours all sorts of things; feeds on its own eggs). But in many of them, certain copies contain sections of unknown origin about the bee, the stork, the tiger, the woodpecker, the spider and the wild boar.

The Greek text of the Physiologus exists only in late MSS., and has to be corrected from the translations. In Syria we have a full copy in a 12th-century Leyden MS., published in J. P. N. Land’s edition (2 vols., Leiden, 1856). From this we have extracted the text of the Physiologus insofar as it can be found in a very late Vatican copy, published by Tychsen; and about the same number in a late MS. of the British Museum (Add. 25878). In Armenian Pitra gave some thirty-two chapters from a Paris MS. (1800). The Physiologus in Christological exaltation in cod. 61 Par. was printed at Leipzig by Dr Hommel in 1877. In Arabic we have fragments at Paris, of which Renan translated a specimen for the Speciologumens solensmene, and another version of thirty-seven chapters at Barcelona, which Lord Lonsdale translated and printed with the Syriac. The Latin MSS. of Bern are, after the Vatican glossary of Anselius, the oldest of which we know; there are others in several libraries, and printed editions of Mai, Heider and Cahier. Besides these, a few fragments of an old abridgment occur in Vallarsi’s edition of Jerome’s works (vol. xii. col. 218). A metrical Physiologus of but twelve chapters is the work of Theobaldus, probably abbot of Monte Cassino (a.d. 1022-1035). From this was imitated the Old-English fragment printed by Dr Wrigg, and afterwards by Macerbus, also the Old-French Sensblo le bestiare d’amours. The prose Physiologus was done in Old High German before 1000, and afterwards into rhyme in the same idiom; since Von der Hagen (1824) its various forms have been printed and collated. The earliest in Iceland, in a Copenhagen MS. of the 13th century, was printed by Professor Th. Möbius in his Analecta norroena (2nd ed., 1877); at the same time he gave it in German in Dr Hommel’s Aetiological Proverbs, which was an abridgment of the same, but found in Grin’s Bibliothek, vol. i. The Provençal (c. 1250), published in Bartsch’s Christomathia prosenode, omits the “morals,” but is remarkable for its peculiarity of form. Before this, there dealt Zeeno of Munich (1273), and after it, by N. Land’s Thaurus (1121), by Guillaume, “clerc de Normandie,” also, about the same period, by Pierre, a clermon of Picardy. All the Old-French materials have not yet been thoroughly examined, and it is far from certain that some versions of the book either remain to be detected or are now lost past recovery. A full account of the history of the Physiologus should also embrace the subjects taken from it in the productions of Christian art, the parodies suggested by them, and the original work of Richard Fournival, and finally the traces left by it upon the encyclopaedic and literary work of the later middle ages.

Nearly all the information now obtainable is to be found in the following publications: Anacreon and the Romance of Physiologus, ed. Ponce de Leon (with woodcuts) (Rome, 1857); another edition, with copper-plates (Antwerp, 1858); S. Eustathii in hexaemeron commentarius, ed. Leo Allatius (Lyons, 1629; cf. H. van Hemert and E. Ortin, Dr. v. 1890-1892); Physiologus, ed. O. G. Tychsen (Koestock, 1705); Classica auctores, ed. Mai, vii. 585-596 (Rome, 1835); G. Heider, in Archiv für Kunde österreich. Geschichtsquellen ii. 554 seq. (Vienna, 1850); Cahier and Martin, Mélanges d’archéologie liturgique, ii. 21-49 (Hague, 1853); Physiologus, ed. G. O. Tychsen (Koestock, 1705); Classica auctores, ed. Mai, vii. 585-596 (Rome, 1835); G. Heider, in Archiv für Kunde österreich. Geschichtsquellen ii. 554 seq. (Vienna, 1850); Cahier and Martin, Mélanges d’archéologie liturgique, ii. 21-49 (Hague, 1853); Cahier, Nouveaux mélanges (1874), p. 166 seq.; J. B. Pitra, Speciologumens solensmene xlvii. seq. 338 seq. 416, 535 (Paris, 1858); Mager, Altegl. Sprachproben (Berlin, 1867), pt. b. p. 55 seq.; J. Victor Carus, Gesch. (Karlsruhe, 1873), p. 1. Neues Cicerone-Syriaca (Leiden, 1874), iv. 31 seq. 115 seq. and in Verslagen en Mededelingen van de kon. akad. van Wetenschappen, 2nd series, vol. iv. (Amsterdam, 1874); Möbius and Hommel in their
PHYSIOLOGY

from Gr. φύσις, nature, and λόγος, discourse), the science or theory of the properties, processes and functions of living organisms. Physiology is distinguished from anatomy as dealing specifically with the functions of an organism, rather than its structure. The two main branches of the science are animal and plant (vegetable) physiology, and in animal physiology that of man stands out as primarily associated with the word.

Ever since men began to take a scientific interest in the problems of life two distinct rival explanatory principles of vital phenomena have claimed attention: a natural and a mystical principle. The first outcome of the scientific attempt to explain vital phenomena after the natural method and by a unitary principle was the doctrine of the Pneuma, held by the followers of Hippocrates, which found its clearest expression in Galen's system. According to this doctrine, the origin of all vital phenomena was a very fine substance, the Pneuma, which was supposed to exist in atmospheric air, to be inhaled into the lungs of man, and thus through the blood to reach all the parts of the body, where it produced vital phenomena. This doctrine—an attempt to explain the phenomena of life which was not altogether natural, but even materialistic—was accepted by the middle ages together with Galen's system. With its translation into the Latin spiritus, however, the conception of the Pneuma lost its original force. The spiritus animale of the middle ages developed ere long into mystical powers, the result being the explanation of vital phenomena by a supernatural theory. Not until the scientific renaissance of the 16th and 17th centuries did views again undergo a change. After the establishment of a scientific method in physiology by William Harvey, and the development of Descartes' mechanical system of regarding living bodies, the natural explanation of vital phenomena once more universally found favour. Two schools arose, which endeavoured by dissimilar methods to find a mechanical explanation of vital phenomena: the iatrophysical, originating with the gifted and versatile Borelli, and the iatrogemical, founded by the Dutchman, F. de la Boë (Sylvius). But when both chemical and physical methods of explanation failed at such problems as, for instance, irritability and evolution, another change in opinion took place. By degrees there emerged once more the tendency to explain vital phenomena by mystical means, finding expression in the Animism of Stahl, to quote an example; and in the second half of the 18th century Vitalism, originating in France, began its victorious march throughout the whole scientific world. Again the opinion came to be entertained that the cause of vital phenomena was a mystical power (force hypermécanique)—that "vital force" which, neither physical nor chemical in its nature, was held to be active in living organisms only. Vitalism continued to be the ruling idea in physiology until about the middle of the 19th century, and its supremacy was only gradually overthrown by the great discoveries in natural science of that century. The chemical discoveries resulting from Wöhler's synthesis of urea first showed that typical products of the animal body, the production of which had hitherto been supposed to be solely the result of the operation of vital force, could be obtained artificially by purely chemical methods. Then above all came the discovery of the law of the Conservation of Energy by Robert Mayer (1814-1878) and Hermann von Helmholtz (1821-1894), and its application to the living organism, by Max Rubner and others, to prove that the manifestations of energy by the organism are simply the result of the quantity of potential energy received into the body by means of food. Finally, the stupendous results arrived at by Darwin and the establishment of the fundamental law of "biogenesis" by Ernst Haeckel, prepared the way for a natural explanation of the enigma of evolution and structure of organisms. Thus by the second half of the 19th century the doctrine of vital force was definitely and finally overthrown to make way for the triumph of the natural method of explaining vital phenomena, which down to the present time has continued to spread and flourish with an unparalleled fertility. It would, it is true, appear as if in our day, after the lapse of half a century, mystical tendencies were again disposed to crop up in the investigation of life. Here and there is heard once more the watchword of Vitalism. But all the so-called neo-vitalistic efforts—such as those of Alexander von Bunge (1803-1890), Georg Evon Rindfleisch (b. 1835), Johannes Reinke (b. 1840) and others—have nothing to do with the old Vitalism. They originate solely in a widespread confusion with regard to the boundaries of natural science, their principal tendency being to amalgamate psychological and speculative questions with problems of purely natural science. In the face of all these efforts, which by their unfortunate designations of naturalism and Neo-Vitalism give rise to entirely false conceptions, and which by their intermingling of psychological questions and questions of natural science have led to mere confusion in research, it is essential that natural philosophy should be called upon to realize its own limits, and above all clearly to understand that the sole concern of physical science is the investigation of the phenomena of the material world. Physiology, as the doctrine of life, must therefore confine itself to the material vital phenomena of organisms. It is self-evident, however, that only such laws as govern the material world will be found governing material vital phenomena—the laws, that is, which have hitherto been brought to their most exact and most logical development by physics and chemistry, or, more generally speaking, by mechanics. The explanatory principles of vital phenomena must therefore be identical with those of inorganic nature—that is, with the principles of mechanics.

The investigation of vital phenomena in this sense requires, in the first place, an exact knowledge of the substratum in which these phenomena are manifested, just as in chemistry ultimate physics and physiology a thorough knowledge of the composition Elements of of the material world is a necessary premise to the investigation of the phenomena of inorganic nature. The knowledge of the composition and structure of organisms has in the course of the scientific development of anatomy attained to an ever-increasing minuteness of detail, without having as yet reached a definite limit. The last important step in this direction was the discovery by Matthias Jakob Schleiden (1804-1881) and Theodor Schwann (1810-1882) that all organisms are built up of elementary living structural components, namely of cells (see CYTOLOGY). The details of the anatomical construction of organisms are described under various appropriate headings, and a general guide to these will be found under the heading of "Vitalism." We would here merely point out that a cell is the simplest particle of living substance which appears to be permanently capable of life. Different elements are essential, however, to the existence of the cell—two, at least, so far as has hitherto been discovered—the protoplasm and the nucleus. It must at present be regarded as at least very doubtful whether the centrosome, which in recent times has been possible to demonstrate as existing in very many cells, and which appears sometimes in the protoplasm, sometimes in the nucleus, is a general and third independent cell-constituent. On the other hand, the number of special constituent parts which appear in various cell-forms is very large. A question which has long been discussed, and which has received special and animated attention, is that with regard to the finer structure of the cell—what, with regard, that is, to the protoplasm and the nucleus alike in it. We have here merely pointed out that one another. One theory maintains that the living cell-substance has a reticular structure; another, that it is fibrous. According to a third theory, the essence of the construction of the cell-substance lies in the granules which it contains; and according to a fourth, it lies in the ground-substance in which these granules are embedded. One view holds this ground substance to be homogeneous, another regards it as possessing a fine foam-structure. It may at present be regarded as
Incontrovertible that living substance is more or less fluid, and
that there does not exist any general structure for all cell-forms.
But in some special cases all the theories which have been quoted
are to a certain extent correct. In different cells there are
terior, fibrous and granular differentiations respectively,
and differentiations in form-structure; in many cells, however,
the protoplasm appears to be beyond doubt homogeneous and
without a distinct structure, and only under certain conditions
to assume changing structures. But the fact which is of most
importance for the right understanding of vital phenomena
is that the cell-substance is always more or less fluid, for only
in a fluid substratum can such intense chemical processes be
enacted as are to be found in every living cell.

Where the analytical powers of the microscope in anatomy
can go no farther, chemical analysis of the composition of the
cell steps in. By its means the discovery is made that there is
no elementary difference between organic and inorganic nature,
for only such chemical elements as are known to exist in the
inorganic world are found in the organic. On the other hand,
however, the living cell-substance possesses chemical compounds
which find analogues nowhere in inorganic nature. The character-
istic organic substances which are present in every cell are
proteids and protid-compounds. Besides these there occur,
widely disseminated, carbohydrates, fats and other organic
substances, which partly originate in the decomposition of
proteids and their compounds, and are partly used for their
construction. Lastly, there are in addition great quantities of
water and some inorganic salts.

Such are the structure and composition of the substratum
in which vital phenomena play their part. When we consider
vital phenomena themselves in the various living
organisms—in protista, plants, animals, man—there
appears an incalculable diversity of phenomena.
Here, however, as in the case of the structure of organisms,
we have to analyse and to penetrate ever farther and deeper
still to reach the fundamental phenomena. We then find
that the great variety of vital manifestations may be traced
back to a few fundamental general groups, which are precisely
the same groups of phenomena as those to be observed in
inorganic nature. All the processes that take place in the organic
world may be regarded from the three different standpoints
of their changes in substance, in energy and in form; for substance,
energy and form are all necessary to our conception of matter.
Accordingly, the general elementary vital phenomena likewise
fall into three groups—metabolism, the mechanism of energy,
and the assumption of form. Every cell, so long as it is living,
takes in certain substances from its environment, submits them
to chemical transformation in its interior, and gives out other
substances. This metabolism is manifested in several special
functions—in nutrition and digestion, respiration and circula-
tion, secretion and excretion. The essence of the whole
process is the fact that while out of these ingested stuffs
living substance is always again being formed by the living
substance which already exists, it is itself continually under-
going decomposition, and the products of this decomposition
are taken up by the substances, and thus both processes go
on simultaneously. Metabolism, however, there is inseparably associated
a transformation of energy. These substances taken in by
the cell contain a large quantity of potential energy, which is
transformed into kinetic energy. This has for its result the
manifold activities of the organism, more especially motion, heat,
electricity and light. Finally, the chemical transformations in
living substance may also manifest themselves outwardly in
changes of form, as is the case generally in the matter of growth,
reproduction and development. The three general elementary

PHYSIOLOGY

As every physical and chemical phenomenon of inorganic
type occurs only under distinct conditions, so vital phenomena are
also dependent upon certain conditions of life. Every living body, every living cell, requires food,
water, oxygen, and, further, a certain temperature
and a certain pressure in its environment. These are the general
conditions of life. But the special conditions on which depends
the continued existence of the individual forms of organism are as
numerous as the forms of organisms themselves. Now, just as
the physicist or chemist varies those conditions under which a
phenomenon occurs in order to get at its causes, so does the
physiologist try to experiment with vital phenomena, altering
the vital conditions: and testing the changes which are thereby
produced. The great importance of this method consists in
the power it gives the experimenter of analysing vital phenomena
systematically from definite points of view. Every change in
its normal vital conditions which produces any effect whatsoever
upon an organism is termed a stimulus. This is the only general
definition we have for a conception which is of such vast import-
tance to physiology. According to it, experimental physiology
is entirely a physiology of stimuli. It further follows from this
conception of stimulation that there must be an enormous
multiplicity of stimuli, since each particular vital condition may
be subjected to some change capable of acting upon it as
stimulus. But, besides this, other factors may be brought to
bear upon organisms which have absolutely no place among
their vital conditions: for instance, many chemical reagents and
electric currents. These influences come under the general
definition of stimulus, because they likewise imply a change
in the conditions under which the organism lives. From their
qualitative nature stimuli are distinguished as chemical, thermal,
photic, mechanical and electrical. Each of these several
varieties may, however, be applied quantitatively in various
degrees of intensity, and may in consequence produce quite
different results. This opens up to experimental physiology
a vast field of research. But the physiology of stimulation is
not only of the greatest value as a means of research: its
importance is much increased by the fact that in nature itself
stimuli are everywhere and constantly acting upon
the organism and its parts. Hence the investigation of their
action comes to be not merely a means, but a direct end
of research.

Although it is not at present possible to define all the laws
that govern stimulation, on the one hand because the number of
stimulating effects known to us in the whole organic
world is as yet too limited, and on the other because
those already known have not yet been thoroughly
analysed, yet it is within our power to classify stimula-
ting effects according to their various characteristics, and
to ascertain a few facts concerning their general and funda-
mental conformity to law. The first fact, apparent from
a glance at a great many of the various forms of stimulation,
is that all their effects are manifested in either a quanti-
tative or a qualitative alteration of the characteristic vital
phenomena of each living object. The quantitative is the
degree of effect, the qualitative is the character of the
stimulus either increases or diminishes the intensity of vital
phenomena. In the first case the effect is one of excitation; in
the second of depression. It is the more important to bear
in mind this twofold operation of stimuli, owing to the fact that
in former times physiologists were very apt to conceive
of excitation and stimulation as identical. It is now, however,
an undisputed fact that depression may also occur as a typical effect
of stimulation. This is most apparent in cases where the same
stimulus that produces excitation may on being applied for
a longer period and with greater intensity, produce depression.
Thus narcotics (alcohol, ether, chloroform, morphia, &c.) on
certain forms of living substance produce the phenomena of
excitation when their action is weak, whereas when it is stronger
they produce complete depression. Thus, likewise, temperature
stimuli act differently upon vital phenomena according to the
degree of temperature: very low temperatures depressing
medium temperatures exciting with increasing intensity, and higher temperatures from a certain height upwards again depressing. The effects of stimulation are not, however, always manifested in merely quantitative changes of the normal vital phenomena. Sometimes, especially in the case of long uninterrupted and chronic stimuli, stimulation is found gradually to produce phenomena which are apparently quite foreign to the normal vital phenomena of the cell in question. Such qualitative alterations of normal vital phenomena are perceptible chiefly in chronic maladies in the cells of different organs (the heart, liver, kidneys, spleen, &c.), in which the vital conditions become gradually more and more modified by the cause of the malady. To this category pertain all the so-called chronic processes of degeneration which in pathology are known as fatty degeneration, mucous degeneration, amyloid degeneration, and so forth. The characteristic element in all these processes is that the normal metabolism is diverted into a wrong channel by the altered vital conditions of the cells of the organ affected, so that substances are formed and accumulated in the cell which are entirely foreign to its normal life. But this class of stimulation is still very obscure as regards causes and inner processes, and it is within the range of possibility that the ultimate cause of the qualitative changes in the normal metabolism is to be found simply in the processes of excitation and depression which chronic stimulation produces in separate parts of the metabolism. Thus, at least with regard to fat-metamorphosis (fatty degeneration), it is highly probable that fat is deposited in the protoplasm simply because, owing to an inadequate supply of oxygen, it cannot, when it originates, be oxidized in the same proportion as it is formed, whereas in the normal cell all fat which originates in metabolism is consumed as soon as it is produced. According to this conception, therefore, fatty degeneration is attributable primarily to a depression of the processes of oxidation in the cell. If we may accept this view as correct with regard to the other metamorphic processes also, the qualitative changes in vital phenomena under the influence of stimuli would after all depend simply upon the excitation or depression of the constituent parts of the vital process, and, according to such a view, all stimuli would act primarily only as exciting or as depressing agents upon the normal process of life.

In accordance with the three groups into which general vital phenomena are divided, it follows as a matter of course that the excitation or depression produced by a stimulus can manifest itself in the cell's metabolism, assumption of form, and manifestation of energy. The effects of excitation upon the production of energy are the most striking, and were therefore in former times frequently thought to have a claim par excellence to rank as stimulating effects. These reactions are, however, in cases where the production of energy is proportionately very great—as with muscle, for instance, which is made to twitch and perform work by a feeble stimulus. Processes of discharge (Auslussungsvorgänge), however, lie at the bottom of cases like these. Potential chemical energy, which is stored up in a considerable quantity in living substance, is converted by the impulse of the stimulus into kinetic energy. Therefore the amount of the effect of stimulation—that is to say, the quantity of work performed—bears no proportion whatever to the amount of energy acting as a stimulus upon the muscle. The amount of energy thus acting may be very small as contrasted with an enormous production of energy on the part of the living substance. It will not do to make generalizations, however, with regard to this process, as was frequently done in former times. All processes of stimulation are not processes of discharge. The cell may undergo far more in depression than in excitation, so that in certain circumstances a stimulus actually diminishes the normal liberation of energy. There is therefore no general law as to the proportion which the amount of energy acting as a stimulus upon living substance bears to the amount of energy liberated.

Among special varieties of stimulation there is one class of stimuli which has attracted particular attention—namely, those which act unilaterally upon free-moving organisms. It is principally with the lowest forms of life that we have here to do—unicellular protista and free-living cells in the bodies of higher organisms (sperm-cells, leucocytes, &c.). When from one direction a stimulus—be it chemical, thermal, photic, electrical, or of any other kind—acts upon these organisms in their medium, they are impelled to move in a course bearing a definite relation to the source of the stimulus—either directly towards that source or directly away from it, more rarely in a course transverse to it. This directive action of stimulation is under such a fixed conformity to law, that it vividly recalls such purely physical processes as, for instance, the attraction and repulsion of iron particles by the poles of a magnet. For example, if light falls from one side upon a vessel full of water containing unicellular green algae, according to the intensity of the light these organisms swim either towards the illuminated side, where they form a compact mass on the edge of the vessel, or away from it, to cluster on the opposite edge. In the same way the bacteria in water are observed to hasten towards or to flee from certain chemical substances, and leucocytes in our bodies act in the same manner towards the metabolic products of pus-forming bacteria which have penetrated into an open wound. The suppurative of wounds is always accompanied by an amazing congregation of leucocytes at the seat of the lesion. Perhaps the most striking effects are those of the constant electric current upon unicellular organisms, since in such a case the motion follows the cause with absolutely automatic regularity, certainty and rapidity. Thus, for example, after the establishment of the current many Infusoria (Paramecium) accumulate at the negative pole with great celerity and without deviation, and turn round again with equal celerity as soon as the direction of the current is altered. As such cases of directive stimulation may occur among all varieties of stimuli whenever stimuli act unilaterally, they have been designated, according to the direction in which they occur in relation to the source of the stimuli, as positive or negative chemotaxis, phototaxis, thermostaxis, galvanotaxis, and so forth. The strange and perplexing element in these phenomena becomes clear to us as soon as we know the characteristic method of locomotion for each form of organism, and whether the stimulus in question in the given intensity exercises an effect of excitation or of depression upon the special form. The direction of motion is the essential mechanical result of unilateral stimulation of the organs of locomotion. Seeing that these reactions are exceedingly widely distributed throughout the whole organic world, and possess a deep biological significance for the existence and continuance of life, the interest they have awakened is thoroughly justified.

One of the most important physiological discoveries of the 19th century was that of the 'Specific Energy of Sense-substances.' Johannes Müller was the first to establish the fact that very different varieties of stimuli applied to the same organ of sense always produce one and the same variety of sensation, and that, conversely, the same stimulus applied to the different organs of sense produces a different sensation in each organ—the one, in fact, which is its specific attribute. Thus, for example, mechanical, electrical and photic stimuli applied to the optic nerve produce no other sensation than that of light; and, conversely, any one variety of stimulus—take the electrical, for example—produces sensations of light, hearing, taste or smell, according as it affects the optic, auditory, gustatory or olfactory nerves. This law of the 'Specific Energy of Sense-substances,' as Johannes Müller (1859-1875) called it, has come to have a highly important bearing upon scientific criticism, since it proves experimentally that things are of the outer world are in no way indivisible, and cannot in any way be divisible, and that what we take to be a single object—the electric current, or a mechanical pressure, for instance—we receive altogether different sensations and form altogether different conceptions according to the sense-organ affected. But this law does not possess significance for psychology alone; as regards physiology also it has a much more general and more comprehensive force than Müller ever anticipated. It holds good, as demonstrated by Ewald Hering (b. 1834) and others,
not of sense-substances only, but of living substance generally. Each cell has its specific energy in Johannes Müller’s sense, and in its extended form there is no more general law for all the operations of stimuli than this law of specific energy. To take examples, whether a muscle be stimulated by a chemical, mechanical, thermal or electrical stimulus the result is in each case the same—namely, a twitching of the muscle. Let a salivary gland be stimulated chemically, mechanically, electrically or in any other way, there always follows the same specific action—a secretion of saliva; no matter what be the kind of stimulus acting upon it, the liver-cell always reacts by producing bile, and so on. On the other hand, one and the same stimulus—the electric current, for example—gives in each form of living substance a specific result: twitching in the muscle, secretion of saliva in the salivary gland, production of bile in the liver-cell, &c. That is, of course, with the proviso that the effect of the stimulus be exciting and not depressing. The following general formulation, however, of the law of specific energy brings the depressing stimuli also within its scope: “Different stimuli produce in each form of living substance an increase or a diminution of its specific activity.” As already observed, it will probably be found that those weak chronic forms of stimulation which produce qualitative changes may also be comprised under this general law.

The knowledge thus far acquired from analysis of vital phenomena and their changes under the influence of stimuli affords but a very indefinite temporary basis for the theory of the actual vital process itself, of which vital phenomena are the outward manifestation. The conceptions to which physiological research has hitherto attained in this matter are of a more or less doubtful nature. The facts contained in them still require to be linked together by hypotheses if we are to obtain even a vague outline of what lies hidden behind the great riddle of life. Such hypotheses, serving as they do to link facts consistently together, are absolutely essential, however, to the further progress of research, and without their aid any systematic investigation would be impracticable. But at the same time it must never be forgotten that these hypotheses are merely provisional, and that whenever they are found to be no longer in harmony with the widening range of new experiences and ideas they must either be proved to be facts or be subjected to modification. This is the point of view from which we must deal with modern ideas concerning the nature of the actual vital process—the mechanism of life.

The fundamental fact of life is the metabolism of living substance which is continually and spontaneously undergoing decomposition, and building itself up anew, with the help of the food-substances it takes in. These processes of decomposition and of reconstruction may be briefly designated as dissimilation (catabolism) and assimilation (anabolism) respectively. Now the question arises: How are we to understand this process of dissimilation and assimilation from a mechanical standpoint? It is quite evident that we have to do with some chemical occurrence; but how are the chemical transformations brought about? There are obviously two possibilities. It is conceivable that the decomposition of food-stuffs and the formation of excretion-products in the cell-body are caused by the repeated casual encounter of a great series of chemical combinations and by their repeatedly reacting upon one another in the same manner, bringing about transformations and forming waste products which are excreted, while at the same time chemical affinites are always taking in from without new chemical combinations (food-stuffs) and uniting them. This theory was in fact occasionally advanced in former times, particularly in its chemical aspect, and the belief was especially entertained that the enzymes in living substance might play an important part in these transformations. This assumption, however, leads to no clear and lucid image of what takes place, and, moreover, draws too largely upon auxiliary hypotheses. It has therefore met with but little acceptance. The other possible explanation of metabolism is that its whole process is confined to one single class of chemical combinations whose tendency it is to be constantly undergoing spontaneous decomposition and regeneration. This latter theory was founded by Ludimar Hermann (b. 1838), Eduard Friedrich Pflüger (b. 1829) and others, and has met with universal recognition because of its naturalness, simplicity and clearness.

Starting with this hypothesis, the path of further research lies clear and well defined before us. In the first place, we are obviously met by the question: What conception are we to form of these combinations on which hinges the whole vital process? Among the organic matters which compose living substance, proteids perform the most important part. Proteids and proteid-compounds form the only organic matter which is never absent from any cell. They form also the greater part of all the organic compounds of the cell, unless reserve-stuffs are accumulated to a considerable extent, and they are by far the most complicated of the compounds of living substance. While animal life is impossible without proteid food, there are, on the other hand, animals which can continue to subsist on proteid alone. This series of facts proves very conclusively that proteids and their compounds play by far the most important part of all organic matter in the processes of life. The idea thus naturally presents itself that the required hypothetical compound forming the central point of metabolism will be found to bear a very close relation to proteids. But another point must be here considered. The proteids and their compounds known to us are, comparatively speaking, stable compounds, which never undergo spontaneous decomposition so long as they are protected from outward injury, whereas the hypothetical combination which lies at the centre of organic metabolism is extraordinarily liable and continually undergoing spontaneous decomposition. Therefore we have to think of ordinary proteids in this case, but of still more complicated combinations, the atoms in the molecule of which have a strong tendency to group themselves in new arrangements. Owing to their fundamental importance, these combinations have been termed “biogens.” When we come to inquire how such labile biogen molecules are built up out of the proteids of food, we find our knowledge very much restricted. Doubtless the intramolecular addition of inspired oxygen has much to do with it; for living substance when deprived of oxygen loses its irritability—that is to say, its tendency to decomposition. The fact that the decomposition of living substance is always associated with the formation of carbonic acid—a circumstance obviously necessitating the aid of oxygen—also points to the absolute indispensability of oxygen in the matter. Pflüger has further suggested that the molecule of living substance owes its lability and its tendency to form carbonic acid when joined to oxygen atoms to cyanogen groups which are contained in it. According to this view, the following is supposed to be the process of the formation of biogen molecules: It is assumed that the biogen molecules already present in living substance take out of the proteids of food certain groups of atoms, and dispose them so as to produce cyanogen-like compounds. The addition of oxygen atoms then brings the biogen molecule to the maximum of its power of decomposition, so that—partly spontaneously, but more especially when impelled by a stimulus—it breaks down somewhat explosively, causing the formation of carbonic acid. In this proceeding, according to the hypothesis which is the most widely accepted and the most fruitful in results, would lie the very germ of the vital process.

If we accept these views as far as their general principle is concerned, we have the decomposition of biogen molecules by those already existing, aided by food-stuffs; dissimilation, the decomposition of biogen molecules. To this primary process, however, is attached a whole series of secondary chemical processes, which serve partly to work upon the food so as to fit it for the building up of biogen molecules, and partly to form out of the direct decomposition-products of the biogen molecules the characteristic secretion-products of living substance (excretions and secretions). The various workings of matter in the cell are rendered very much more
complex by the circumstance that the living cell exhibits various morphological differentiations—all above, the differentiation in protoplasm and nucleus. Again, a transformation of energy is inseparably connected with metabolism. Along with food and oxygen potential chemical energy is continually being introduced into the cell, to be accumulated in the biogen molecules, and at their decomposition transformed into kinetic energy, which finds an outlet in the various manifestations of energy in the cell—motion, heat, and so forth. In the light of this hypothesis the operations of stimuli also become comprehensible. Seeing that there is an initial tendency to the occurrence of certain definite chemical processes, which are associated with the reconstruction and decomposition of biogen molecules, various stimuli will either further or hinder the course of this metabolic series. A cell which is exposed to no outward disturbance, and which continues always in the unvarying medium provided by an exact sufficiency of food, will be in "metabolic equilibrium"—that is, its assimilation and its dissipation will be equal (A = D). When, however, the influence of external stimuli is brought to bear upon them—that is to say, any change in their environment vital conditions—A and D will either be altered in similar proportion, or their mutual equilibrium will be disturbed. In the former case the vital processes will merely be intensified in their course; in the latter and usual case the result will be determined according to the part of metabolism excited or depressed.

When the effect of a stimulus is to excite D continuously in a high degree without correspondingly increasing A, the result is a dying off—an atrophy. In the contrary case, when A remains continuously greater than D, the result is growth, increase and reproduction of the cell. Experience proves, however, that A and D stand in a certain relation of mutual dependence to each other, with the result that when D has been increased by a stimulus, for example, A correspondingly increases during the stimulation, and continues to do so after its cessation, till the loss in living substance produced by the stimulation of D is eventually made good, and metabolic equilibrium is restored. The muscle may be taken as an example of this self-regulation of metabolism common to all living substance (Hering's Selbststeuerung des Stoffwechsels).

When a muscle has been fatigued by some stimulation causing an enormous increase of D, there is a corresponding spontaneous increase in A. After some time the muscle is observed to have recovered. It has once more become capable of performing work; its metabolism is again in equilibrium.

The vital phenomena of the cell may be derived mechanically from metabolism and the changes it undergoes under the influence of stimuli. Our ability to do this will increase more rapidly as we become better acquainted with the details of the metabolism of the cell itself. The foregoing outline must be regarded, of course, as embodying only a fragmentary hypothesis, which can serve as a guide for further research only so long as it does not clash with facts, and which must be amplified, specialized and developed with the widening of specific knowledge regarding the cell's metabolism. The relations already known are so exceedingly complex that only by slow degrees can we pursue the investigation of separate fragments of the entire metabolic series. The differentiation of nucleus and protoplasm in the living substance of the cell alone gives rise to an extraordinary complication in the metabolic process, for these two parts of the cell stand in the most complicated correlation with one another as well as with the surrounding medium—a fact of which the experiments made by vivisection abundantly bear witness. The wider field of study is also embracing abundant evidence. The farther such knowledge advances, the more rounded, clear and free from hypotheses will become our conception of the cell's metabolism. But the cell is the elementary component part of all organisms, and from the life of individual cells is constructed the life of the separate tissues and various organs, and thus of the entire organism. Hence the cell is the only vital element which the organism possesses, and therefore the investigation of the vital processes in its separate cells leads ultimately to a knowledge regarding the mechanism of life in the whole.

Vegetable physiology is dealt with in the article PLANTS: Physiology. For details of different parts of the animal body, see Animal Heat; Respiratory System; Vascular System; Touch; Smell; Taste; Vision; Hearing; Voice; Muscle and Nerve; Sleep; Hypnotism; Brain; Spinal Cord; Sympathetic System; Blood; Lymph; Phagocytes; Digestive Organs; Nutrition, &c.

The principal modern English textbooks of animal physiology are those of Sir Charles Foster (1895), A. E. Schäfer (1898), Noël Paton (1908), Halliburton (1909), and Starling (1906). See, however, the bibliographical notes to the separate articles. (M. V.)

PIACENZA (Lat. Placentia), a town and episcopal see of Emilia, Italy, the capital of the province of Piacenza, 42° 57' N. of Milan and 91 m. N.W. of Bologna by rail. Pop. (1906), 39,786. It lies on the Lombard plain, 217 ft. above sea-level, near the right bank of the Po, which here is crossed by road and railway bridges, just below the confluence of the Trebbia. It is still surrounded by walls with bastions and fosse in a circuit of 2 mi. The cathedral was erected between 1122 and 1235, in the Lombard Romanesque style, under the direction of Santo da Sambuceto, on the site of a church of the 9th century which had been destroyed by earthquake. The west front has three doors with curious pillared porches. The campanile is a massive square brick tower 223 ft. high; the iron cage attached to one of its windows was put up in 1495 by Ludovico il Moro for the confinement of persons guilty of treason or sacrilege. The crypt is a large church supported by one hundred columns. The entire edifice has been restored since 1808, and the frescoes by Guercino and Caracci, which decorate parts of its roof, though good in themselves, are inappropriate to its severe style. Sant' Antonio, which was the cathedral church till 877, is supposed to have been founded by St Victor, the first bishop of Piacenza, in the 4th century, and restored in 903; it was rebuilt in 1104, and altered in 1857. It was within its walls that the deputies of the Lombard League swore to the conditions of peace ratified in 1183 at Constance. The Gothic brick vestibule (Il Paradiso) on the north side is one of the older parts of the building. San Francesco, a spacious Gothic edifice begun by the Franciscans in 1278, was erected on the site of the palace of Ubertino Landi, a leader of the Ghibelline party. S. Savino, a fine Romanesque building of A.D. 903 (well restored in 1903), contains a mosaic pavement of this period with curious representations, including one of a game of chess. S. Sisto, which dates from 1499, and takes the place of the church founded in 874 by Angilberga (consort of the emperor Louis II.), lost its chief attraction when Raphael's Sistine Madonna (now in Dresden) was sold by the monks in 1754 to Frederick Augustus III. Its place, however, is occupied by a copy by Avanzini, and there are also several good Intarsias by Bartolomeo da Busseto. S. Sepolcro and S. Maria della Grancia, both examples of the Gothic style, are both good early Renaissance churches; the latter is rich in frescoes by Pordenone. S. Anna, dating from 1334, was the church of the barefooted Carmelites. Of the secular buildings the most interesting is the Palazzo Communale, begun in 1281, one of the finest buildings of its kind in Italy. The square in front is known as the Piazza dei Cavalli, from the two bronze equestrian statues of Ranuccio (1620) and his father Alexander, prince of Parma, governor of the Netherlands (1629). Both were designed by Francesco Mochi. The Palazzo dei Tribunali and the Palazzo degli Sciti are fine early Renaissance brick buildings with terra-cotta decorations. The huge Farnese palace was begun after Vignola's designs by Margaret of Austria in 1558, but it was never completed, and since 1800 it has been used as barracks. Other buildings or institutions of note are the old and the new palazzo of the municipio, and the two palazzi of the Jesuits. From 1803 to 1823, the great hospital dating from 1471, the library presented to the commune in 1846 by the marquis Ferdinando Landi, and the Passerini library founded in 1685. The Museo Civico, formed in 1903, contains collections of antiquities (though many of the Roman antiquities of Piacenza have passed to the museum of Parma), some good Flemish tapestries and a few pictures. The castle erected by Antonio da Sangallo the younger has been demolished. Piacenza is the junction of the Milan and Bologna line with that from Voghera and Turin. From Codogno, 7 m.

to the north, a branch line runs to Cremona. By road Placentia is 88 m. north-east of Genoa. The town has an arsenal, a technical and arts school, and various industries—iron and brass works, foundries, silk-throwing, printing works and flour-mills.

Placentia was a Roman colony in 218 B.C. While its walls were yet unfinished it had to repulse an attack by the Gauls, and in the latter part of 218 it afforded protection to the remains of the Roman army under Scipio which had been defeated in the great battle on the Trebia. In 205 it withstood a protracted siege by Hasdrubal. Five years later the Gauls burned the city; and in 190 it had to be recruited with three thousand families. In 187 it was connected with Ariminum and the south by the construction of the Via Aemilia. Later on it became a very important road centre; the continuation northwards of the Via Aemilia towards Milan, with a branch to Ticinum, crossed the Po there, and the Via Postumia from Cremona to Dertona and Genoa passed through it. Later still Augustus reconstructed the road from Dertona to Vade, and into Gallia Narbonensis, and gave it the name of Julia Augusta from Placentia onwards. The rectangular arrangement of the streets in the centre of the town, through which passes the Via Aemilia, is no doubt a survival from Roman times. Placentia is mentioned in connexion with its capture by Cinna and a defeat of the forces of Carbo in the neighbourhood (82 B.C.), a mutiny of Julius Caesar's garrison (50 B.C.), another mutiny under Augustus (40 B.C.), the defence of the city by Spurinna, Otho's general, against Caecina, Vitellius's general (A.D. 69), and the defeat of Aurelian by the Marcomanni outside the walls (A.D. 271). In 540 Totilla reduced Placentia by famine. Between 997 and 1035 the city was governed by its bishops, who had received the title of count from Otto III. At Roncaglia, 5 m. to the east, the emperor Conrad II. held the diet which passed the Salic law. In the latter part of the 12th century it was one of the leading members of the Lombard League. For the most part it remained Guelph, though at times, as when it called in Galeazzo Visconti, it was glad to appeal to a powerful Ghibelline for aid against its domestic tyrants. In 1447 the city was captured and sacked by Francesco Sforza. Having been occupied by the papal forces in 1512, it was in 1545 united with Parma (q.v.) to form an hereditary duchy for Pierluigi Farnese, son of Paul III. In 1746 a battle between the Franco-Spanish forces and the Austrians was fought outside the city walls, and in 1756 it was occupied by the French. In 1848 Placentia was the first of the towns of Lombardy to join Piedmont; but it was reoccupied by the Austrians till 1859.

PIANOFORTE (Ital. piano, soft, and forte, loud). The group of keyed stringed musical instruments, among which the piano-forte is latest in order of time, has been invented and step by step developed with the modern art of music, which is based upon the simultaneous employment of different musical sounds. In January 1709 the "organum," a rectangular system of accompaniment to the voice, consisting of fourths and octaves below the melody and moving with it; and the organ (q.v.), the earliest keyed instrument, was, in the first instance, the rude embodiment of this idea and convenient means for its expression. There was as yet no keyboard of the modern day. Sliders were drawn out like modern draw-stops, to admit the compressed air necessary to make the pipes sound. About the same time arose a large stringed instrument, the organistrum, the parent of the now obsolete hurdy-gurdy; as the organ needed a blower as well as an organist, so the player of the organistrum required a handle-turner, by whose aid the three strings of the instrument were made to sound simultaneously upon a wheel, and, according to the well-known sculptured relief of St George de Boscherville, one string was manipulated by means of a mallet. The previous organistrum is shown in the lower right hand corner of the full page miniature of a fine 12th century psalter of English workmanship, forming part of the Hunterian collection in University Library, Glasgow. No. 31 in Catalogue of the Exhibition of Illuminated MSS. at the Burlington Fine Arts Club (1908).

row of stoppers or tangents pressed inwards to produce the notes. The other strings were drones, analogous to the drones of the bagpipes, but originally the three strings followed the changing organum.

In the 11th century, the epoch of Guido d'Arezzo, to whom the beginning of musical notation is attributed, the Pythagorean monochord, with its shifting bridge, was used in the singing schools to teach the intervals of the plain-song of the church. The practical necessity, not merely of demonstrating the proportionate relations of the intervals, but also of initiating pupils into the different gradations of the church tones, had soon after Guido's time brought into use quadruplex-fashioned monochords, which were constructed with scales, analogous to the modern practice with thermometers which are made to show both Réaumur and Centigrade, so that four lines were indicated as many authentic and as many plagal tones. This arrangement found great acceptance, for Aribó, writing about fifty years after Guido, says that few monochords were to be found without it. Had the clavichord then been known, this make-shift contrivance would not have been used. Aribó strenuously endeavoured to improve it, and "by the grace of God" invented a monochord measure which, on account of the rapidity of the leaps he could make with it, he named a wild-goat (caprea). Jean de Murs (Musica speculativa, 1323) teaches how true relations may be found by a single-string monochord, but recommends a four-stringed one, properly a tetra-chord, to gain a knowledge of unfamiliar intervals. He describes the musical instrument in a manner appropriate to his time, but does not mention the clavichord or monochord with keys, which could not have been then invented. Perhaps one of the earliest forms of such an instrument, in which stoppers or tangents had been adopted from the organistrum, is shown in fig. 1, from a wood carving of a vicar choral or organist, preserved in St Mary's church, Shrewsbury. The latest date to which this interesting figure may be attributed is 1460, but the conventional representation shows that the instrument was then already of a past fashion, although perhaps still retained in use and familiar to the carver.

In the Weimar Wunderbuch, a MS. dated 1440, with pen and ink miniatures, is given a "clavichordium" having 8 short and apparently 16 long keys, the artist has drawn 12 strings in a rectangular case, but no tangents are visible. A keyboard of balanced keys existed in the little portable organ known as the regal, so often represented in old carvings, paintings and stained windows. Vitruvius, De architectura, lib. x. cap. xi., translated by Newton, describes a balanced keyboard; but the key apparatus is more particularly shown in The Pneumatics of Hero of Alexandria, translated by Bennet Woodcroft (London, 1851). In confirmation of this has been the remarkable discovery at Carthage of a terra-cotta model of a Hydraulikon or water organ, dating from the 2nd century A.D., in which a balanced keyboard of 18 or 19 keys is shown. It seems likely the balanced keyboard was lost, and afterwards reinvented. The name of

FIG. 1.—Earliest existing representation of a Keyed Stringed Instrument, from St Mary's, Shrewsbury (primitive Clavichord). Before 1460.
PIANOFORTE

regal was derived from the rule (regula) or graduated scale of
keys, and its use was to give the singers in religious processions
the note or pitch. The only instrument of this kind known to
exist in the United Kingdom is at Blair Atholl, and it bears the
very late date of 1630. The Brussels regal may be as modern.
These are instances of how long a some-time admired musical
instrument may remain in use after its first intention is forgotten.
We attribute the adaptation of the narrow regal keyboard to
what was still called the monochord, but was now a complex of
monochords over one resonance board, to the latter half of the
14th century; it was accomplished by the substitution of tangents
fixed in the future ends of the balanced keys for the movable
bridges of the monochord or such stoppers as are shown in the
Shrewsbury carving. Thus the monochordium or “payre of
monochordis” became the clavicordium or “payre of clavi-
chords” — pair being applied, in the old sense of a “pair of
steps,” to a series of degrees. This use of the word to imply
gradation was common in England to all keyed instruments;
thus we read, in the Tudor period and later, of a pair of regals,
organs, or virginals. Ed. van der Straeten reproduces a so-
called regal keyboard of the 14th century, in MS. of the public
library at Ghent. The treatise is anonymous, but was written in
the same MS. bear dates 1503 and 1504. Van der Straeten is
of opinion that the drawing may be assigned to the middle of
the 15th century. The scribe calls the instrument a clavicim-
balum, and this is undoubtedly correct; the 8 strings in the
drawing are stretched from back to front over a long sound-
board, the longest strings to the left; 8 keys, 4 long and 4 short
with levers to which are attached the jacks, are seen in a
horizontal line behind the keyboard, and behind them again
are the names of the notes a, b, c, d, e, f, g, h. In the
Weimar Wunderbuch is a pen-and-ink sketch of the “clavicim-
balum” placed upon a table, in which we recognize the
familiar outline of the harpsichord, but on a smaller scale.
The keyboard shows white and black notes—the latter short
keys, one between each group of two white keys, precisely as
in the instrument reproduced by Van der Straeten—but no
mechanism is visible under the strings.

The earliest known record of the clavichord occurs in some
rules of the minnesingers, dated 1409, preserved at Vienna.
The monochord is named with it, showing a differentiation of
these instruments, and of them from the clavicymbalum, the
keyed cymbal, cembalo (Italian), or psaltery. From this we
learn that a keyboard had been thus early adapted to that
favourite medieval stringed instrument, the “cembalo” of
Bocaccio, the “sautrie” of Chaucer. There were two forms of
the psaltery: (1) the trapeze, one of the oldest representations
of which is to be found in Orcagna’s famous Trionfo della Morte
in the Campo Santo at Pisa, and another by the same painter
in the National Gallery, London; and (2) the contemporary “testa
di porco,” the pig’s head, which was of triangular shape as
the name suggests. The trapeze psaltery was strung horizontally,
the “istromento di porco” either horizontally or vertically—
the notes, as in the common dulcimer, being in groups of three
or four unisons. In these differences of form and stringing we
see the cause of the ultimate differentiation of the spinet and
harpichord. The compass of the psalteries was nearly that of
Guido’s scale; but according to Mersenne, the lowest interval was
a fourth, G to C, which is worthy of notice as anticipating the later
short measure of the spinet and organ.

The simplicity of the clavichord inclines us to place it, in
order of time, before the clavicymbalum or clavicembalo; but
we do not know how the sounds of the latter were at first excited.
There is an indication as to its early form to be seen in the
court of the Certosa near Pavia, which compares in probable date
with

6 ii. 226.

the Shrewsbury example. We quote the reference to it from Dr
Ambros. He says a carving represents King David as holding
an “istromento di porco” which has eight strings and as many
keys lying parallel to them; inside the body of the instrument,
which is open at the side nearest the right hand of King David,
he touches the keys with the right hand and damps the strings
with the left. The attribution of archaism applies with equal
force to this carving as to the Shrewsbury one, for when the
monastery of Certosa near Pavia was built by Ambrogio Fossana
in 1472, chromatic keyboards, which imply a considerable
advance, were already in use. There is an authentic representa-
tion of a chromatic keyboard, painted not later than 1426, in the
St Cecilia panel (now at Berlin) of the famous Adoration of the
Lamb by the Van Eycks. The instrument depicted is a positive
organ, and it is interesting to notice in this realistic painting
that the keys are evidently boxwood, as in the Italian spinets of late
date, and that the angel plays a common chord — A with the
right hand, F and C with the left. But diatonic organs with
eight steps or keys in the octave, which included the B flat and the
B natural, as in Guido’s scale, were long preserved, for
Praetorius speaks of them as still existing nearly two hundred
years later. This diatonic keyboard, we learn from Sebastian
Virdung (Musica getuschi und auszegzen, Basel, 1511), was the
keyboard of the early clavichord. We reproduce his diagram as
the only authority which we have for the disposition of the one short
key.

The extent of this scale is exactly Guido’s. Virdung’s diagram
of the chromatic is the same as our own familiar keyboard, and
comprises three octaves and a note, from F below the bass stave
to G above the treble. But Virdung tells us that even then
clavicords were made longer than four octaves by repetition of
the same order of keys. The introduction of the chromatic order
he attributes to the study of Boethius, and the consequent
endeavour to restore the three musical genera of the Greeks —
the diatonic, chromatic and enharmonic. But the last named had
not been attained. Virdung gives woodcuts of the clavichordium,
The Fig. 2.—Diatonic Clavichord Keyboard (Guido’s Scale) from
Virdung. Before 1511.

virginal, the clavicymbalum and the clavicytherium. We
reproduce three of them (figs. 3, 6 and 12), omitting the virginal
as obviously incorrect. Writers on musical instruments have
continually repeated these drawings without discerning that in
the printing they are reversed, which puts the keyboards entirely
wrong, and that in Lusciniius’s Latin translation of Virdung
(Musurgia, sive praxis musicae, Strasbourg, 1536), which has been
hitherto chiefly followed, two of the engravings, the clavicim-
balum and the clavicytherium, are transposed, another cause of
error. Martin Agricola (Musica instrumentalis, Wittenberg,
1530) has copied Virdung’s illustrations with some differences
of perspective, and the addition, here and there, of errors of his
own.

1 Geschichte der Musik, ii. 544—555.
Still vulgarly known as monochord, Virdung’s clavichord was really a box of monochords, all the strings being of the same length. He derives the clavichord from Guido’s monochord as he does the virginal from the psaltery, but, at the same time, confesses he does not know when, or by whom, either instrument was invented. We observe in this drawing the short sound-board, which always remained a peculiarity of the clavichord, and the straight sound-board bridge—necessarily so when all the strings were of one length. To gain an angle of incidence for the tangents against the strings the keys were made crooked, an expedient further rendered necessary by the “fretting”—three tangents, according to Virdung, being directed to stop as many notes from each single group of three strings tuned in unison; each tangent thus made a different vibrating length of string. In the drawing the strings are merely indicated. The German for fret is Bund, and such a clavichord, in that language, is known as a “gebundenes Clavichord” both fret (to rub) and Bund (from binden, to bind) having been taken over from the lute or viol. The French and Italians employ “touche” and “tasto,” touch. Praetorius who wrote a hundred years later than Virdung, says two, three and four tangents were thus employed in stopping. There are extant small clavichords having three keys and tangents to one pair of strings and others have no more than two tangents to a note formed by a pair of strings, instead of three. Thus seven pairs of strings suffice for an octave of twelve keys, the open notes being F, G, A, B flat, C, D, E flat, and by an unexplained peculiarity: perhaps derived from some special estimation of the notes which was connected with the church modes. A and D are throughout left free from a second tangent. A corresponding value of these notes is shown by their independent of chromatic alteration in tuning the double Irish harp, as explained by Vincentio Galliè in his treatise on music (Dialogo della musica, Florence, 1581). Aßling, who died in 1762, speaks of another fretting, but it must have been an adaptation to the modern major scale, the “free” notes being E and B. Clavichords were made with double fretting up to about the year 1700—that is to say, to the epoch of J. S. Bach, who, taking advantage of its abolition and the consequent use of independent pairs of strings for each note, was enabled to tuned in all keys equally, which had been impossible so long as the fretting was maintained. The modern scales having become established, Bach was now able to produce his “Drei vollkommenste Clavier,” the first collection of preludes and fugues in all the twenty-four major and minor scales for a clavichord which was tuned, as to concordance and dissonance, equally.

The oldest clavichord, here called manicordo (as French manucerde, from monochord), known to exist is that shown in fig. 4. It will be observed that the lowest octave is here already bridge, indispensable for the vibration, besides acting as the sound exciters (fig. 5). The common damper to all the strings is a list of cloth, interwoven behind the tangents. As the tangents quitted the strings the cloth immediately stopped all vibration. Too much cloth would diminish the tone of this already feeble instrument, which gained the name of “dumb spinet” from its use. In the clavichord in Rubens’s St Cecilia (Dresden Gallery)—interesting as perhaps representing that painter’s own instrument—the damping cloth is accurately painted. The number of keys there shown is three octaves and a third, F to A—the same extent as in Handel’s clavichord now in the museum at Maidstone (an Italian instrument dated 1726, and not fretted), but with the peculiarity of a combined chromatic and short octave in the lowest notes, to which we shall have to refer when we arrive at the spinet; we pass it by as the only instance we have come across in the clavichord.

The clavichord must have gone out of favour in Great Britain and the Netherlands early in the 17th century, before its expressive power, which is of the most tender and intimate quality, could have been, from the nature of the music played, observed, the more brilliant and elegant spinet being preferred to it. Like the other keyboard instruments it had no German name, and can hardly have been of German origin. Holbein, in his drawing of the family of Sir Thomas More, 1528, now at Basel, indicates the place for “Klavikord und ander Seytinspill.” But it remained longest in use in Germany—until even the beginning of the 19th century. It was the favourite “Klavier” of the Bachs. Besides that of Handel already noticed there are in existence clavichords the former possession of which is attributed to Mozart and Beethoven. The clavichord was obedient to a peculiarity of touch possible on no other keyboard instrument. This is described by C. P. Emmanuel Bach in his famous essay on playing and accompaniment, entitled Versuch über die wahre Art das Klavier zu spielen (“An Essay on the True Way to play Keyboard Instruments.”) It is the Bebung (trembling), a vibration in a melody note of the same nature as the tremolo frequently employed by violin players to heighten the expressive effect; it was gained by a repeated movement of the fleshy end of the finger while the key was still held down. The Bebung was indicated in the notation by dots over the note to be affected by it, perhaps showing how many times the note should be repeated. According to the practice of the Bachs, as handed down to us in the above mentioned essay, great smoothness of touch was required to play the clavichord in tune. As with the monochord, the means taken to produce the sound disturbed the accuracy of the string measurement by increasing tension, so that a key touched too firmly in the clavichord, by unduly raising the string, sharpened the pitch, an error in playing deprecated by C. P. Emmanuel Bach. This answers the assertion which has been made that J. S. Bach could not have been nice about tuning when he played from preference on an instrument of uncertain intonation.

The next instrument described by Virdung is the virginal (virginalis, proper for a girl), a parallelogram in shape, having the same projecting keyboard and compass of keys the same as the clavichordium. Here we can trace derivation from the psaltery in the sound-board covering the entire inner surface of the instrument and in the triangular disposition of the strings. The virginal in Virdung’s drawing has an impossible position with reference to the keyboard, which renders its reproduction as an illustration useless. But in the next drawing, the clavichordium, this is rectified, and the drawing, reversed on account of the keyboard, can be accepted as roughly representing the instrument so called (fig. 6). There would be
no difference between it and the virginal were it not for a peculiarity of keyboard compass, which emphatically refers itself to the Italian "spinet," a name unnoticed by Virdung or by his countryman Arnold Schlick, who, in the same year 1511, published his Spiegel der Orgelmacher (Organ-builders' Mirror), and named the clavicordium and clavichord as familiar instruments. In the first place, the keyboard, beginning apparently with B natural, instead of F, makes the clavichord smaller than the virginal, the strings in this arrangement being shorter; in the next place it is almost certain that the Italian spinet compass, beginning apparently upon a semitone, is identical with a "short measure" or "short octave" organ compass, a very old keyboard arrangement, by which the lowest note, representing B, really sounded G and C sharp in like manner A. The origin of this may be deduced from the psaltery and many representations of the regal, and its object appears to have been to obtain dominant basses for cadences, harmonious closes having early been sought for as giving pleasure to the ear. Authority for this practice is to be found in Mersenne, who, in 1636, expressly describes it as occurring in his own spinet (espinette). He says the keyboards of the spinet and organ are the same. Now, in his Latin edition of the same work he renders

earliest used we have no evidence. The little crow-quill points project from centred tongues in uprights of wood known as "jacks" (fig. 7), which also carry the dampers, and arising by the depression of the keys in front, the quills set the strings vibrating as they pluck them in passing, springs at first of steel, later of bristle, giving energy to the twang and governing their return. J. C. Scaliger in Poeticae libri septem (1561, p. 51, c. 1.) states that the Clavicimbalum and Harpsichordium of his boyhood are now called Spinets on account of those quill points (ab illis mucronibus), and attributes the introduction of the name "spinet" to them (from spina, a thorn). We will leave harpsichordium for the present, but the early identity of clavicimbalum and spinetta is certainly proved. Scaliger's etymology remained unquestioned until Signor Ponsicoli of Florence discovered another derivation. He found in a rare book entitled Conclusione nel suono dell'organo, di D. Adrian Banchieri (Bologna, 1608), the following passage, which translated reads: "Spinetta was thus named from the inventor of that oblong form, who was one Maestro Giovanni Spinetti, a Venetian; and I have seen one of those instruments, in the possession of Francesco Stivori, organist of the Maggiore church of Montagnana, within which was this inscription—Joannes Spinetis Veneti fecit, a.d. 1503." Scaliger's and Banchieri's statements may be combined, as there is no discrepancy of dates, or we may rely upon whichever seems to us to have the greater authority, always bearing in mind that neither invalidates the other. The introduction of crow-quill points, and adaptation to an oblong case of an instrument previously in a trapeze form, are synchronous; but we must accept 1503 as a late date for one of Spinetti's instruments, seeing that the altered form had already become common, as shown by Virdung, in another country as early as 1511. After this date there are frequent references to spinets in public records and other documents, and we have fortunately the instruments themselves to put in evidence, preserved in public museums and in private collections. A spinet dated 1490 was shown at Bologna in 1888; another old spinet in the Conservatoire, Paris, is a pentagonal instrument made by Francesco di Portalupis at Verona, 1523. The Milanesi Rossi were famous spinet-makers, and have been accredited (La Nobiltad di Milano, 1893) with an improvement in the form which we believe was the recessing of the keyboard, a feature which had previously entirely projected; by the recessing a greater width was obtained for the sound-board. The spinets by Annibale Rosso at South Kensington, dated respectively 1555 (fig. 8) and 1577, show this

 alteration, and may be compared with the older and purer form of one, dated 1568, by Marco Jadora (also known as Marco "dalle spinette," or "da cembali"). Besides the pentagonal spinet, there was an heptagonal variety; they had neither covers nor stands, and were often withdrawn from decorated cases when required for performance. In other instances, as in the 1577 Rosso spinet, the case of the instrument itself was richly adorned. The apparent compass of the keyboard in Italy generally exceeded four octaves by a semitone, E to F; but we may regard the lowest natural key as usually C, and the lowest sharp key as usually D, in these instruments, according to "short measure."

The rectangular spinet, Virdung's "virginal," early assumed in Italy the fashion of the large "cassoni" or wedding chests. The oldest we know of in this style, and dated, is the fine specimen belonging to M. Terme which figures in L'Art decoratif (fig. 9). Virginal is not an Italian name;

---

1 A. J. Ellis (History of Musical Pitch, p. 318) sees the B in Mersenne's outline diagram.
the rectangular instrument in Italy is "spinetta tavola." In England, from Henry VII. to Charles II., all quilled instruments (stromenti di penne), without distinction as to form, were known as virginals. It was a common name, equivalent to the contemporary Italian clavicordo and Flemish clavisingel. From the latter, by apocope, we arrive at the French clavecin—the French clavier (clave, a key), a keyboard, being in its turn adopted by the Germans to denote any keyboard stringed instrument.

Mersenne (op. cit., liv. iii., p. 158) gives three sizes for spinets—one 2½ ft. wide, tuned to the octave of the "ton de chappelle" (in his day a half tone above the present English medium pitch), one of 3 ft. tuned to the fourth below, and one of 5 ft. tuned to the octave below the first, the last being therefore tuned in unison to the chapel pitch. He says his own spinet was one of the smallest it was customary to make, but from the lettering of the keys in his drawing it would have been of the second size, or the spinet tuned to the fourth. The octave spinet, of trapeze form, was known in Italy as "ottavina" or "spinetta di serenata." It had a less compass of keys than the larger instrument, being apparently three and two-thirds octaves, E to C—which by the "short measure" would be four octaves, C to C. We learn from Praetorius that these little spinets were placed upon the larger ones in performance; their use was to heighten the brilliant effect. In the double rectangular clavisingel of the Netherlands, in which there was a movable octave instrument, we recognize a similar intention. There is a fine spinet of this kind at Nuremberg. Praetorius illustrates the Italian spinet by a form known as the "spinetta traversa," an approach towards the long clavichembalo or harpsichord, the tuning pins being immediately over the keyboard. This transposed spinet, more powerful than the old trapeze one, became fashionable in England after the Restoration, Haward, Keene, Slade, Player, Baudin, the Hitchcocks, Mahoon, Haxby, the Harrir family, and others having made such "spinets" during a period for which we have dates from 1664 to 1784. Pepys bought his "Espinette" from Charles Haward for £6, July 12, 1664.

The spinets of Keene and Player, made about 1700, have frequently two divided sharps at the bass end of the keyboard, as in the description by Mersenne, quoted above, of a spinet with short measure. Such divided sharps have been assumed to be quarter tones, but enharmonic intervals in the extreme bass can have no justification. From the tuning of Handel's Italian clavichord already mentioned, which has this peculiarity, and from Praetorius we find the further halves of the two divided sharps were the chromatic semitones, and the nearer halves the major thirds below i.e. the dominant fourths to the next natural keys. Thomas Hitchcock (for whom there are dates 1664 and 1703 written on keys and jacks of spinets bearing Edward Blunt's name and having divided bass sharps) made a great advance in constructing spinets, giving them the wide compass of five octaves, from G to G, with very fine keyboards in which the sharps were inlaid with a slip of the ivory or ebony, as the case might be, of the Naturals. Their instruments, always numbered, and not dated as has been sometimes supposed, became models for contemporary and subsequent English makers.

We have now to ask what was the difference between Scaliger's harpsichordum and his clavicymbal. Galilei, the father of the astronomer of that name (Dialogo della musica antica e moderna, Florence, 1581), says that the harpsichord was so named from having resembled an "arpa giacente," a prostrate or "couchè" harp, proving that the clavicymbal was at first the trapeze-shaped spinet; and we should therefore differentiate harpsichord and clavicymbal as, in form, suggested by or derived from the harp and psaltery, or from a "testa di porco" and an ordinary trapeze psaltery. We are inclined to prefer the latter. The Latin name "clavicymbalum," having early been replaced by spinet and virginal, was in Italy and France bestowed upon the long harpichord, and was continued as clavicembalo (gravecembalo, or familiarly cembalo only) and clavecin. Much later, after the restoration of the Stuarts, the first name was accepted and naturalized in England as harpsichord, which we will define as the long instrument with quills, shaped like a modern grand piano, and resembling a wing, from which it has gained the German appellation "Flügel." We can point out no long instrument of this kind so old as the Roman cembalo at South Kensington (fig. 17). It was made by Geronimo of Bologna in 1521, two years before the Paris Porta- lupis spinet. The outer case is of finely tooled leather. It has a spinet keyboard with a compass of nearly four octaves, E to D. The natural keys are of boxwood, gracefully arched in front. The key-ends of the Ib cembalo was afterwards carried out to the normal four octaves. There is an existing example, dated 1626, with the bass keys carried out without sharps in long measure (unfortunately altered by a restorer). It is surprising to see with what steady persistence the Italians adhered to their original model in making the instrument. As late as the epoch of Cristofori, and in his 1722 cembalo at Florence, we still find the independent outer case, the single keyboard, the two unisons, without power to reduce to one by using stops. The Italians have been as conservative with their forms of spinet, and are to this day with their organs. The startling "piano e forte" of 1598, brought to light from the records of the house of D'Este by Count Valdrighi of Modena, after much consideration and a desire to find in it an anticipation of Cristofori's subsequent invention of the pianoforte, we are disposed to regard as the ordinary cembalo with power to shift, by a stop.

The harpsichord Cristofori made for Prince Ferdinand de Medici in 1702, recently acquired by Mr. Stearns, of Detroit, and presented by him to the University of Michigan, U.S.A., there are three keyboards, thus arranged: 1st, highest keyboard, octave strings; 2nd, middle, octave strings, no unisons; 3rd, lowest keyboard, both unisons. A harpsichord similarly designed with three keyboards, inscribed "Vincentius Sodi Florentinum Facit, Anno Domini 1779," was presented by Mrs. J. Crosby Brown to the Metropolitan Museum, New York.

1 In the Kraus Museum Catalogue (1901), No. 559.

2 See Van der Straeten, vi. 122.
from two unisons (forte) to one string (piano), at that time a Flemish practice, and most likely brought to Italy by one of the Flemish musicians who founded the Italian school of composition. About the year 1600, when accompaniment was invented for monody, large cembalos were made for the orchestras to bring out the bass part, the performer standing to play. Such an instrument was called "archicembalo," a name also applied to a large cembalo, made by Vito Trasuntino, a Venetian, in 1606, intended by thirty-one keys in each of its four octaves—one hundred and twenty-five in all—to restore the three genera of the ancient Greeks. How many attempts have been made before and since Trasuntino to purify intonation in keyboard instruments by multiplying keys in the octave? Simultaneously with Father Smith's well-known experiment in the Temple organ, London, there were divided keys in an Italian harpsichord to gain a separate G sharp and A flat, and a separate D sharp and E flat.

Double keyboards and stops in the long cembalo or harpsichord came into use in the Netherlands early in the 16th century. We find them imported into England. The following citations, quoted by Rimbault in his History of the Pianoforte, but imperfectly understood by him, are from the privy purse expenses of King Henry VIII, as extracted by Sir Harris Nicolas in 1827.

"1530 (April). Item the vi dayse past to William Lewes for ii payer of virginalls in one coffer with iii stops brought to Gresnewiche ii ii. And for ii payer of virginalls in one coffer brought to the More other lii ii."

Now the second instrument may be explained, virginals meaning any quilled instrument, as a double spinet, like that at Nuremberg by Martin van der Beest, the octave division being movable. But the first cannot be so explained; the four stops can only belong to a harpsichord, and the two pair instrument to a double keyed one, one keyboard being over, and not by the side of the other. Again from the inventory after the king's death (see Brit. Mus. Harl. MS. 1419) fol. 247—

"Two pair of new long Virginalls made harp-fashion of Cipres, with keys of ivory, having the King's Arms crowned and supported by his Grace's beasts within a garter gift, standing over the keys."

We are disposed to believe that we have here another double keyboard harpsichord. Rimbault saw in this an upright instrument, such as Virdung's clavicethium (fig. 12). Having since seen the one in the Kraus Museum, Florence, it seems that Virdung's drawing should not have been reversed; but he has mistaken the wires acting upon the jacks for strings, and omitted the latter stretched horizontally across the soundboard (see Clavi- cethium). We read in an inventory of the furniture of Warwick Castle, 1584, "a faire paire of double virginalis," and in the Hengrave inventory, 1603, "one great paire of double virginalls." Hans Ruckers, the great clavichord maker of Antwerp, lived too late to have invented the double keyboard and stops, evident adaptations from the organ, and the octave string (the invention of which was so long attributed to him), which incorporated the octave spinet with the large instrument, to be henceforth playable without the co-operation of another performer, was already in use when he began his work. Until the last harpsichord was made by Joseph Kirkman, in 1798, scarcely an instrument of the kind was constructed, except in Italy, without the octaves. The harpsichord as known throughout the 18th century, with piano upper and forte lower keyboard, was the invention of Hans Ruckers's grandson, Jean Ruckers's nephew, Jan Couchet, about 1640. Before that time the double keyboards in Flemish harpsichords were merely a transposing expedient, to change the pitch a fourth, from plagal to authentic and vice versa, while using the same groups of keys. Fortunately there is a harpsichord existing with double keyboards unaltered, date 1638, belonging to Sir Bernard Samuelson, formerly in the possession of Mr. Spence, of Florence, made by Jean Ruckers, the keyboards being in their original position. It was not so much invention as beauty of tone which made the Ruckers' harpsichords famous. The Ruckers harpsichords in the 18th century were fetching such prices as Bologna lutes did in the 17th or Cremona violins do now. There are still many specimens existing in Belgium, France and England. Handel had a Ruckers harpsichord, now in Buckingham Palace; it completes the number of sixty-three existing Ruckers instruments catalogued in Grove's Dictionary of Music and Musicians.

After the Antwerp make declined, London became preeminent for harpsichords—the representative makers being Jacob Kirckmann and Burckhard Tschudi, pupils of a Flemish master, one Tabel, who had settled in London, and whose business Kirckmann continued through marriage with Tabel's widow. Tschudi was of a noble Swiss family belonging to the canton of Glarus. According to the custom with foreign names obtaining at that time, by which Hachdel became Handel, and Schmidt Smith, Kirckmann dropped his final s and Tschudi became Shudi, but he resumed the full spelling in the facies of the splendid harpsichords he made in 1766 for Frederick the Great, which are still preserved in the New Palace, Potsdam. By these great makers the harpsichord became a larger, heavier-strung and more powerful instrument, and fancy stops were added to vary the tone effects. To the three shifting registers of jacks of the octave and first and second unisons were added the "lute," the charm of which was due to the favouring of high harmonics by plucking the strings close to the bridge, and the "harp," a surging or muting effect produced by impeding the vibration of the strings by contact of small pieces of buff leather. Two pedals were also used, the left-hand one a combination of a unison and lute. This pedal, with the "machine" stop, reduced the upper keyboard to the lute register, the pluck of which acted upon the strings near the wrest-plank bridge

---

1 Invented by Nicola Vicentino; see L'Antica musica ridotta alla moderna pratica (Rome, 1555).
only; the lower keyboard to the second unison. Releasing the machine stop and quitting the pedal restores the first unison on both keyboards and the octave on the lower. The right-hand pedal was to raise a hinged portion of the top or cover and thus gain some power of "swell" or crescendo, an invention of Roger Pleniuss, to whom also the harp stop may be rightly attributed. This ingenious harpsichord maker had been stimulated to gain these effects by the nascent pianoforte which, as we shall find, he was the first to make in England. The first idea of pedals for the harpsichord to act as stops appears to have been John Hayward's (c1672) as early as 1676, as we learn from Mace's *Musick's Monument*, p. 235. The French makers preferred a kind of knee-pedal arrangement, known as the "genouillère," and sometimes a more complete muting by one long strip of buff leather, the "sounde." As an improvement upon Plenius's clumsy swell, Shudi in 1769 patented the Venetian swell, a framing of louvres, like a Venetian blind, which opened by the movement of the pedal, and becoming in England a favourite addition to harpsichords, was early transferred to the organ, in which it replaced the rude "nag's-head" swell. A French harpsichord maker, Marius, whose name is remembered from a futile attempt to design a pianoforte action, invented a folding harpsichord, the "clavecim brisé," by which the instrument could be disposed of in a smaller space. One, which is preserved at Berlin, probably formed part of the camp baggage of Frederick the Great.

It was formerly a custom with kings, princes and nobles to keep large collections of musical instruments for actual playing purposes, in the domestic and festive music of their courts. There are records of their inventories, and it was to keep such a collection in playing order that Prince Ferdinand dei Medici engaged a Paduan harpsichord maker, Bartolommeo Cristofori, the man of genius who invented and produced the pianoforte. We fortunately possess the record of this invention in a literary form from a well-known writer, the Marchese Scipione Maffei; his description appeared in the *Giornale degli Scrittori d'Italia*, a publication conducted by Apostolo Zeno. The date of Maffei's paper was 1711. Rimbault reproduced it, with a technically imperfect translation, in his *History of the Pianoforte*. We learn from it that in 1709 Cristofori had completed four "gravecembali col piano e forte"—keyed-palisanders with soft and loud—three of them being of the long or usual harpsichord form. A synonym in Italian for the original cembalo (or psaltery) is "salterio," and if it were struck with hammers it became a "salterio tedesco" (the German hackbrett, or chopping board), the latter being the common dulcimer. Now the first notion of a pianoforte is a dulcimer with keys, and we may perhaps not be wrong in supposing that there had been many attempts and failures to put a keyboard to a dulcimer or hammers to a harpsichord before Cristofori successfully solved the problem. The sketch of his action in Maffei's essay shows an incomplete stage in the invention, although the kernel of it—the principle of escapement or the controlled rebound of the hammer—is already there. He obtains it by a centred lever (linguetta mobile) or hopper, working, when the key is depressed by the touch, in a small projection from the centred hammer-butt. The return, governed by a spring, must have been uncertain and incapable of further regulating than could be obtained by modifying the strength of the spring.

Moreover, the hammer had each time to be raised the entire distance of its fall. There are, however, two pianofortes by Cristofori, dated respectively 1720 and 1726, which show a much improved, we may even say a perfected, construction, for the whole of an essential piano movement is there. The earlier instrument (now in the Metropolitan Museum, New York) has undergone considerable restoration, the original hollow hammer-head having been replaced by a modern one, and the hammer-butt, instead of being central by means of the holes provided by Cristofori himself for the purpose, having been lengthened by a leather hinge screwed to the block; but the 1726 one, which is in the Kraus Museum at Florence, retains the original leather hammer-heads. Both instruments possess alike a contrivance for determining the radius of the hopper, and both have been unexpectedly found to have the "check" (ital. paramartello), which regulates the fall of the hammer according to the strength of the blow which has impelled it to the strings. After this discovery of the actual instruments of Cristofori there can be no longer doubt as to the attribution of the invention to him in its initiation and its practical completion with escapement and check. To Cristofori we are indebted, not only for the power of playing piano and forte, but for the infinite variations of tone, or *nuances*, which render the instrument so delightful.

But his problem was not solved by the devising of a working action; there was much more to be done to install the pianoforte as a new musical instrument. The resonance, that most subtle

and yet all-embracing factor, had been experimentally developed to a certain perfection by many generations of spinet and harpsichord makers, but the resistance structure had to be thought out again. Thicker stringing, rendered indispensable to withstand even Cristofori's light hammers, demanded in its turn a stronger framing than the harpsichord had needed. To make his structure firm he considerably increased the strength of the block which holds the tuning-pins, and as he could not do so without materially adding to its thickness, he adopted the bold expedient of inverting it; driving his wrest-pins, harp-fashion, through it, so that tuning was effected at their upper, while the wires were attached to their lower, ends. Then, to guarantee the security of the case, he ran an independent string-block round it of stouter wood than had been used in harpsichords, in which block the hitch-pins were driven to hold the farther ends of the strings, which were spaced at

1 Mace describes a primitive swell contrivance for an organ 65 years before Plenius took out his patent (1741).

2 The invention of the piano by Cristofori, and him alone, is now past discussion. What is still required to satisfy curiosity would be the discovery of a Fort Bien or Frederici square piano, said to antedate by a year or two Zumpf's invention of the instrument in London. The name Fort Bien was derived, consciously or unconsciously, from the Saxon German peculiarity of interchanging B and P. Among Mozart's effects at the time of his death was a Forte-Basso mit Pedal (see *Vierzehnter jährlicher Bericht des Mozarteum, "Salzburg," Dec. 19, 1791*). Also wanted is the "old movement" for the long or grand pianos, sometimes quoted in the Broadwood day-books of the last quarter of the 18th century with reference to the displacement by the Backers English action.

3 Communicated by Baron Alexander Kraus (May 1908).
equal distances (unlike the harpsichord), the dampers lying between the pairs of unisons.

Cristofori died in 1731. He had pupils, but did not found a school of Italian pianoforte-making, perhaps from the peculiar Italian conservatism in musical instruments we have already remarked upon. The essay of Scipione Maffei was translated into German, in 1725, by König, the court poet at Dresden, and friend of Gottfried Silbermann, the renowned organ builder and harpsichord and clavicord maker. Incited by this publication, and perhaps by having seen in Dresden one of Cristofori's pianofortes, Silbermann appears to have taken up the new instrument, and in 1726 to have manufactured two, which J. S. Bach, according to his pupil Agricola, pronounced failures. The trebles were too weak; the touch was too heavy. There has long been another version to this story, viz. that Silbermann borrowed the idea of his action from a very simple model contrived by a young musician named Schroeter, who had left it at the electoral court in 1721, and, quitting Saxony to travel, had not afterwards claimed it. It may be so; but Schroeter's letter, printed in Mitzler's Bibliothek, dated 1736, is not supported by any other evidence than the recent discovery of an altered German harpsichord, the hammer action of which, in its simplicity, may have been taken from Schroeter's diagram, and would sufficiently account for the condemnation of Silbermann's earliest pianofortes if he had made use of it. In either case it is easy to distinguish between the lines of Schroeter's interesting communications (to Mitzler, and later to Marpurg) the bitter disappointment he felt in being left out of the practical development of so important an instrument.

But, whatever Silbermann's first experiments were based upon, it was ascertained, by the investigations of A. J. Hipkins, that he, when successful, adopted Cristofori's pianoforte without further alteration than the compass and colour of the keys and the style of joinery of the case. In the Silbermann grand pianofortes, in the three palaces at Potsdam, known to have been Frederick the Great's, and to have been acquired by that monarch prior to J. S. Bach's visit to him in 1747, we find the Cristofori framing, stringing, inverted wrest-plank and action complete. Fig. 15 represents the instrument on which J. S. Bach played in the Town Palace, Potsdam.

It has been repeatedly stated in Germany that Frederici, of Gera in Saxony, an organ builder and musical instrument maker, invented the square or table-shaped piano, the fort bien, as he is said to have called it, about 1738-1760. No square piano by this maker is forthcoming, though an "upright grand 1 piano," made by Domenico del Mela in 1739, with an action adapted from Cristofori's, has been discovered by Signor Fonsicchi of Florence. Victor Frederici of Leipzig, however, acquired a Frederici "upright grand" piano, dated 1745 (fig. 16). In Frederici's upright grand action we have not to do with the ideas of either Cristofori or Schroeter; the movement is practically identical with the hammer action of a German clock, and has its counterpart in a piano at Nuremberg; a fact which needs further elucidation. We note here the earliest example of the leather hinge, afterwards so common in piano actions and only now going out of use. Where are we to look for Schroeter's copyist if not found in Silbermann, Frederici, or, as we shall presently see, perhaps J. G. Wagner? It might be in the harpsichord we have mentioned, which, made in 1712 by one Brock for the elector of Hanover (afterwards George I. of England), was by him presented to the Protestant pastor of Schulpfort, near Hanover, and has since been rudely altered into a pianoforte (fig. 17). There is an altered harpsichord in the museum at Basel which appears to have been no more successful. But an attempted combination of harpsichord and pianoforte appears as a very early intention. The English poet Mason, the friend of Gray, bought such an instrument at Hamburg in 1755, with "the cleverest mechanism imaginable."

It was only under date of 1763 that Schroeter published for the first time a diagram of his proposed invention, designed more than forty years before. It appeared in Marpurg's Kritische Briefe (Berlin, 1764). Now, immediately after, Johann Zumpe, a German in London, who had been one of Shudi's workmen, invented or introduced (for there is some tradition that Mason had to do with the invention of it) a square piano, which was to become the most popular domestic instrument. It would seem that Zumpe was in fact not the inventor of the square piano, which appears to have been well known in Germany before his date, a discovery made by Mr George Rose. In Paul de Wit's Musical Instrument Museum—formerly in Leipzig, now transferred to Cologne—there is a small square piano, 27 in. long, 10 in. wide and 4 1/2 in. high, having a contracted keyboard of 3 octaves and 2 notes. The action of this small instrument is practically identical in every detail with that of the square pianofortes made much later by Zumpe (Paul de Wit, Katalog des musikhistorischen Museums, Leipzig, 1903. No. 55, illustration, p. 38). Inside is inscribed: "Friedrich Hildebrand, Instrumentenmacher in Leipzig, Quergasse," with four figures

For arguments in favour of Schroeter's claim to the invention of the pianoforte see Dr Oscar Paul, op. cit., pp. 85-104, who was answered by A. J. Hipkins in Grove's Dict. of Music and Musicians. Mason really invented the "cellestina" (known as Adam Walker's patent No. 1920), as we know from the correspondence of Mary Granville. Under date of the 11th of January 1775 she describes this invention as a short harpsichord 2 ft. long, but played with the right hand only. The left hand controlled a kind of violin bow, which produced a charming soundante, in character of tone between the violin tone and that of musical glasses.

2 This translation, published at Hamburg and reproduced in extenso, may be read in Dr Oscar Paul's Geschichte des Claviers (Leipzig, 1868).
almost illegible. Paul de Wit refers to the instrument to the middle of the 18th century. It has all the appearance of being a reduced copy of a well-established type, differing very little from the later models, except that it has no dampers. It seems probable that this small instrument is a converted clavichord, and that the action may have been suggested by Schroeter's model, left in 1721 at the Electoral Court of Saxony. Burney tells us all about Zumpe; and his instruments still existing would fix the date of the first at about 1765. Fétis narrates, however, that he began the study of the piano on a square piano made by Zumpe in 1762. In his simple "old man's head" action we have the nearest approach to a realization of Schroeter's simple idea. It will be observed that Schroeter's damper would stop all vibration at once. This defect is overcome by Zumpe's "mopstick" damper. Another piano action had, however, come into use about that time or even earlier in Germany. The discovery of it in the simplest form is to be attributed to V. C. Mahillon, who found it in a square piano belonging to Henri Gosselin, painter, of Brussels. The principle of this action is that which was later perfected by the addition of a good escape ment by Stein of Augsburg, and was again later experimented upon by Sebastian Erard. Its origin is perhaps due to the contrivance of a piano action that should suit the shallow clavichord and permit of its transformation into a square piano; a transformation, Schroeter tells us, had been going on when he wrote his complaint. It will be observed that the hammer is, as compared with other actions, reversed, and the axis rises with the key, necessitating a fixed means for raising the hammer, in this action effected by a rail against which the hammer is jerked up. It was Stein's merit to graft the hopper principle upon this simple action; and Mozart's approbation of the invention, when he met with it at Augsburg in 1777, is expressed in a well-known letter addressed to his mother. No more "blocking" of the hammer, destroying all vibration, was henceforth to vex his mind. He had found the instrument that for the rest of his short life replaced the harpsichord. V. C. Mahillon secured for his museum the only Johann Andreas Stein piano which is known to remain. It is from Augsburg, dated 1780, and has Stein's escapement action, two unisons, and the knee pedal, then and later common in Germany.

Mozart's own grand piano, preserved at Salzburg, and the two grand pianos (the latest dated 1790) by Huhn of Berlin, preserved at Berlin and Charlottenburg, because they had

![Fig. 21.—Stein's Action (the earliest so-called Viennese), 1780. Belonged to Queen Luise of Prussia, follow Stein in all particulars. These instruments have three unisons upwards, and the muting movement known as celeste, which no doubt Stein had also. The wren-plank is not inverted; nor is there any imitation of Cristofori. We may regard Stein, coming after the Seven Years' War which had devastated Saxony, as the German inventor of the grand piano. Stein's instrument was accepted as a model, as we have seen, in Berlin as well as Vienna, to which city his business was transferred in 1794 by his daughter Nanette, known as an accomplished pianist and friend of Beethoven, who at that time used Stein's pianos. She had her brother in the business with her, and had already, in 1793, married J. A. Streicher, a pianist from Stuttgart, and distinguished as a personal friend of Schiller. In 1802, the brother and sister dissolving partnership, Streicher began himself to take his full share of the work, and on Stein's lines improved the Viennese instrument, so popular for many years and famous for its lightness of touch, which contributed to the special character of the Viennese school of pianoforte playing. Since 1862, when Steinway's example caused a complete revolution in German and Austrian piano-making, the old wooden cheap grand piano has died out. We will quit the early German piano with an illustration (fig. 22) of an early square piano action in an instrument made by Johann Gottlob Wagner of Dresden in 1783. This interesting discovery of Mahillon's introduces us to a rude imitation (in the principle) of Cristofori, and it appears to have no relation whatever to the clock-hammer motion seen in Frederic's.

Burney, who lived through the period of the displacement of the harpsichord by the pianoforte, is the only authority to whom we can refer as to the introduction of the latter instrument into England. He tells us, in his gossiping way, that the first harpsichord that came to England was made by an English monk at Rome, a Father Wood, for an English gentleman, Samuel Crisp of Cheshington; the tone of this instrument was superior to that produced by quills, with the added power of the shades of piano and forte, so that, although the touch and mechanism were so imperfect that nothing quick could be executed upon it, yet in a slow movement like the "Dead March" in Saul it excited wonder and delight. Fulke Greville afterwards bought this instrument for 100 guineas, and it remained unique in England for several years, until Plenius, the inventor of the lyraichord, made a pianoforte in imitation of it. In this instrument the touch was better, but the tone was inferior. We have no date for Father Wood. Plenius produced his lyraichord, a sostenente

---

harpsichord, in 1745. When Mason imported a pianoforte in 1755, Fulke Greville's could have been no longer unique. The Italian origin of Father Wood’s pianoforte points to a copy of Cristofori, but the description of its capabilities in no way confirms this supposition, unless we adopt the very possible theory that the instrument had arrived out of order and there was on one in London who could put it right, or would perhaps divine that it was wrong. Burney further tells us that the arrival in London of J. C. Bach in 1759 was the motive for several of the second-rate harpsichord makers trying to make pianofortes, but with no particular success. Of these Americus Backers (d. 1775), said to be a Dutchman, appears to have gained the first place. He was afterwards the inventor of the so-called English action, and as this action is based upon Cristofori’s we may suppose he at first followed Silberman in copying the original inventor. There is an old play-bill of Covent Garden in Messrs Broadwood’s possession dated the 16th of May 1767, which has the following announcement:—

"End of Act i. Miss Bickler will sing a favourite song from Judith, accompanied by Mr. Dibdin on a new instrument call’d Piano Forte."

The mind at once reverts to Backers as the probable maker of this novelty. Backers’s “Original Forte Piano” was played at the Thatched House in St James’s Street, London, in 1773. Ponscich has found a Backers grand piano at Pistoria, dated that year. It was Backers who produced the action continued in the direct principle by the firm of Broadwood, or with the reversed lever and hammer-butt introduced by the firm of Collard in 1835.

The escapement lever is suggested by Cristofori’s first action, to which Backers has added a contrivance for regulating it by means of a button and screw. The check is from Broadwood; Cristofori’s second action. No more durable action has been constructed, and it has always been found equal, whether made in England or abroad, to the demands of the most advanced virtuosi. John Broadwood and Robert Stodart were friends, Stodart having been Broadwood’s pupil; and they were the assistants of Backers in the installation of his invention. On his deathbed he commended it to Broadwood’s care, but Stodart appears to have been the first to advance it—Broadwood being probably held back by his partnership with his brother-in-law, the son of Shudi, in the harpsichord business. (The elder Shudi had died in 1773.) Stodart soon made a considerable reputation with his “grand” pianofortes, a designation he was the first to give them. In Stodart’s grand piano we first find an adaptation from the lyric chord of Plinius, of steel arches between the

wrest-plank and belly-rail, bridging the gap up which the hammers rise, in itself an important cause of weakness. These are not found in any contemporary German instruments, but may have been part of Backers’s.

Imitation of the harpsichord by “octaving” was at this time an object with piano makers. Zumpe’s small square piano had met with great success; he was soon enabled to retire, and his imitators, who were legion, continued his model with its hand stops for the dampers and sourdine, with little change but that which straightened the keys from the divergences inherited from the clavichord. John Broadwood took this domestic instrument first in hand to improve it, and in the year 1780 succeeded in entirely reconstructing it. He transferred the wrest-plank and pins from the right-hand side, as in the clavichord, to the back of the case, an improvement universally adopted after his patent, No. 1379 of 1783, expired. In this patent we first find the damper and piano pedals, since universally accepted, but at first in the grand pianofortes only. Zumpe’s action remaining with an altered damper, another inventor, John Geib, patented (No. 1571 of 1786) the hopper with two separate escapements, one of which soon became adopted in the grasshopper of the square piano, it is believed by Geib himself; and Petzold, a Paris maker, appears to have taken later to the escapement effected upon the key. We may mention here that the square piano was developed and continued in England until about the year 1860, when it went out of fashion.

To return to John Broadwood—having launched his reconstructed square piano, he next turned his attention to the grand piano to continue the improvement of it from the point where Backers had left it. The grand piano was in framing and resonance entirely on the harpsichord principle, the sound-board bridge being still continued in one undivided length. The strings, which were of brass wire in the bass, descended in notes of three unisons to the lowest note of the scale. Tension was left to chance, and a reasonable striking line or place for the hammers was not thought of. Theory requires that the notes of octaves should be multiples in the ratio of 1 to 2, by which, taking the treble clef C at one foot, the lowest F of the five-octave scale would require a vibrating length between the bridges of 12 ft. As only half this length could be conveniently afforded, we see at once a reason for the above-mentioned deficiencies. Only the three octaves of the treble, which had lengths practically ideal, could be tolerably adjusted. Then the striking-line, which should be at an eighth or not less than a ninth or tenth of the vibrating length, and had never been cared for in the harpsichord, was in the lowest two octaves out of all proportion, with corresponding disadvantage to the tone. John Broadwood did not venture alone upon the path.
towards rectifying these faults. He called in the aid of two men of science—Tiberius Cavallo, who in 1788 published his calculations of the tension, and Dr Gray, of the British Museum. The problem was solved by dividing the sound-board bridge, the lower half of which was advanced to carry the bass strings, which were still of brass. The first attempts to equalize the tension and improve the striking-place were here set forth, to the great advantage of the instrument, which in its wooden construction might now be considered complete. The greatest pianists of that epoch, except Mozart and Beethoven, were assembled in London—Clementi, who first gave the pianoforte its own character, raising it from being a mere variety of the harpsichord, his pupils Crainer and for a time Hummel, later on John Field, and also the brilliant virtuosi Dussek and Steibelt. To please Dussek, Broadwood in 1791 carried his five-octave, F to F, keyboard, by adding keys upwards, to five and a half octaves, F to E'. In 1794 the additional keys to octaves C, which Shudi had first introduced in his double harpsichords, was given to the piano. Steibelt, while in England, instituted the familiar signs for the employment of the pedals, which owes its charm to excitement of the imagination instigated by power over an acoustical phenomenon, the sympathetic vibration of the strings. In 1799 Clementi founded a pianoforte manufactory, to be subsequently developed and carried on by Messrs Collard.

The first square piano made in France is said to have been constructed in 1776 by Sebastian Erard, a young Alsatian. In 1786 he came to England and founded the London manufactory of harps and pianofortes bearing his name. That eminent mechanic and inventor is said to have at first adopted for his pianos the English models.

However, in 1794 and 1801, as is shown by his patents, he was certainly engaged upon the elementary action described as appertaining to Gosselin's piano, of probably German origin. In his long-continued labour of inventing and constructing a double escapement action, Erard appears to have sought to combine the English power of gradation of tone with the German lightness of touch. He took out his first patent for a "repetition" action in 1808, claiming for it "the power of giving repeated strokes without missing or failure, by very small angular motions of the key itself." He did not, however, succeed in producing his famous repetition or double escapement action until 1821; it was then patented by his nephew Pierre Erard, who, when the patent expired in England in 1835, proved a loss from the difficulties of carrying out the invention, which induced the House of Lords to grant an extension of the patent.

Erard invented in 1808 an upward bearing to the wrest-plank bridge, by means of agraflées or stubs of metal through holes in which the strings are made to pass, bearing against the upper side. The wooden bridge with down-bearing strings is clearly seen in relation with upward-striking hammer, the tendency of which must be to raise the strings from the bridge, to the detriment of the tone. A long brass bridge on this principle was introduced by William Stodart in 1832. A pressure-bar bearing of later introduction is claimed for the French maker, Bord. The first to see the importance of iron sharing with wood (ultimately almost supplanting it) in pianoforte framing was a native of England and a civil engineer by profession, John Isaac Hawkins, known as the inventor of the ever-pointed pencil. He was living at Philadelphia, U.S.A., when he invented and first produced the familiar cottage pianoforte—"portable grand" as he then called it. He patented it in America, his father, Isaac Hawkins, taking out the patent for him in England in the same year, 1800. It will be observed that the illustration here given (fig. 27) represents a wreck; but a draughtsman's restoration might be open to question.

There had been upright grand pianos as well as upright harpsichords, the horizontal instrument being turned up upon its wider end and a keyboard and action adapted to it. William Southwell, an Irish piano-maker, had in 1798 tried a similar experiment with a square piano, to be repeated in later years by W. F. Collard of London; but Hawkins was the first to make a piano, or pianino, with the strings descending to the floor, the keyboard being raised, and this, although at the moment the chief, was not his only merit. He anticipated nearly every discovery that has since been introduced as novel. His instrument (fig. 28) is in a complete iron frame, independent of the case; and in this frame, strengthened by a system of iron resistance rods combined with an iron upper bridge, his sound-board is entirely suspended. An apparatus for tuning by mechanical screws regulates the tension of the strings, which are of equal length throughout. The action, in metal supports, anticipates Wornum's in the checking, and still later ideas in a contrivance for repetition. This remarkable bundle of inventions was brought to London and exhibited by Hawkins himself;
but the instrument being poor in the tone failed to bring him pecuniary reward or the credit he deserved. Southwell appears to have been one of the first to profit by Hawkins's ideas by bringing out the high cabinet pianoforte, with hinged sticker action, in 1807. All that he could, however, patent in it was the simple damper action, turning on a pivot to relieve the dampers from the strings, which is still frequently used with such actions. The next steps for producing the lower or cottage upright piano were taken by Robert Wornum, who in 1811 produced a diagonally, and in 1813 a vertically, strung one. Wornum's perfected crank action (fig. 29) was not complete until 1826, when it was patented for a cabinet piano; but it was not really introduced until three years later, when Wornum applied it to his little "piccolo." The principle of this central lever check action was introduced into Paris by Pleyel and Pape, and thence into Germany and America.

It was not, however, from Hawkins's invention that iron became introduced as essential to the structure of a pianoforte. This was due to William Allen, a young Scotsman in the employ of the Stodarts. He devised a metal system of framing intended primarily for compensation, but soon to become, in other hands, a framing for resistance. His idea was to meet the divergence in tuning caused in brass and iron strings by atmospheric changes by compensating tubes and plates of the same metals, guaranteeing their stability by a cross baton of stout wooden bars and a metal bar across the wrest-plank. Allen, being simply a tuner, had not the full practical knowledge for carrying out the idea. He had to ally himself with Stodart's foreman, Thom; and Allen and Thom patented the invention in January 1820. The firm of Stodart at once acquired the patent.

We have now arrived at an important epoch in pianoforte construction—the abolition, at least in England and France, of the wooden construction in favour of a combined construction of iron and wood, the former material gradually asserting pre-eminence. Allen's design is shown in fig. 30. The long bars shown in the diagram are really tubes fixed at one end only; those of iron lie over the iron or steel wire, while those of brass lie over the brass wire, the metal plates to which they are attached being in the same correspondence. At once a great advance was made in the possibility of using heavier strings than could be stretched before, without danger to the durability of the case and frame. The next step was in 1821, to a fixed iron string-plate, the invention of one of Broadwood's workmen, Samuel Hervé, which was in the first instance applied to one of the square pianos of that firm. The great advantage in the fixed plate was a more even solid counterpoise to the drawing or tension of the strings and the abolition of their undue length behind the bridge, a reduction which Isaac Carter had tried some years before, but unsuccessfully, to accomplish with a plate of wood. So generally was attention now given to improved methods of resistance that it has not been found possible to determine who first practically introduced those long iron or steel resistance bars which are so familiar a feature in modern grand pianos. They were experimented on as substitutes for the wooden bracing by Joseph Smith in 1798; but to James Broadwood belongs the credit of trying them first above the sound-board in the treble part of the scale as long ago as 1808, and again in 1818; he did not succeed, however, in fixing them properly. The introduction of fixed resistance bars is really due to observation of Allen's compensating tubes, which were, at the same time, resisting. Sebastian and Pierre Erard seem to have been first in the field in 1823 with a complete system of nine resistance bars from treble to bass, with a simple mode of fastening them through the sound-board to the wooden beams beneath, but, although these bars appear in their patent of 1824, which chiefly concerned their repetition action, the Erards did not either in France or England claim them as of original invention, nor is there any string-plate combined with them in their patent. James Broadwood, by his patent of 1827, claimed the combination of string-plate and resistance bars, which was clearly the completion of the wood and metal instrument, differing from Allen's in the nature of the resistance being fixed. Broadwood, however, left the brass bars out, but added a fourth bar in the middle to the three in the treble he had previously used. It must be borne in mind that it was the trebles that gave way in the old wooden construction before the tenor and bass of the instrument. But the weight of the stringing was always increasing, and a heavy close overspinning of the bass strings had become general. The resistance bars were increased to five, six, seven, eight and, as we have seen, even nine, according to the ideas of the different English and French makers who used them in their pursuit of stability.

The next important addition to the grand piano in order of time was the harmonic bar of Pierre Erard, introduced in 1838. This was a gun-metal bar of alternate pressing and drawing power by means of screws which were tapped into the wrest-plank immediately above the treble bearings, making that part of the instrument nearly immovable; this favoured the production of higher harmonics to the treble notes, recognized in what we commonly call "ring." A similar bar, subsequently extended by Broadwood across the entire wrest-plank, was to prevent any tendency in the wrest-plank to rise, from the combined upward drawing of the strings. A method of fastening the strings on the string-plate depending upon friction, and thus dispensing with "eyes," was a contribution of the Collards, who had retained James Stewart, a man of considerable inventive power, who had been in America with Chickering. This invention was introduced in 1827. Between 1847 and 1849

1 Sometime foreman to the pianoforte maker Mort, who attracted much attention by a piano with sostenente effect, produced by a roller and silk attachments in 1817. But a sostenente piano, however perfect, is no longer a true piano such as Beethoven and Chopin wrote for.
Mr Henry Fowler Broadwood, son of James, and grandson of John Broadwood, and also great-grandson of Shudi (Tschudi), invented a grand pianoforte to depend practically upon iron, in which, to avoid the conspicuous inequalities caused by the breaking of the scale with resistance bars, there should be no bar parallel to the strings except a bass bar, while another flanged resistance bar, as an entirely novel feature, crossed over the strings from the bass corner of the wrest-plank to a point upon the string-plate where the greatest accumulation of tension strain was found. Broadwood did not continue, without some compromise, this extreme renunciation of ordinary resistance means. After the Great Exhibition of 1851 he employed an ordinary straight bar in the middle of his concert grand scale, his smaller grands having frequently two such as well as the long bass bar. After 1862 he covered his wrest-plank with a thick plate of iron into which the tuning pins screw as well as into the wood beneath, thus avoiding the crushing of the wood by the constant pressure of the pin across the pull of the string, an ultimate source of danger to durability.

The introduction of iron into pianoforte structure was differently and independently effected in America, the fundamental idea there being to use a single casting for the metal plate and bars, instead of forging or casting them in separate pieces. Alpheus Babcock was the pioneer in this kind of metal construction. He also was bitten with the compensation notion, and had cast an iron ring for a square piano in 1825, which, although not a success, gave the clue to a single casting resistance framing, successfully accomplished by Conrad Meyer, in Philadelphia, in 1833, in a square piano which still exists, and was shown in the Paris Exhibition of 1878. Meyer's idea was improved upon by Jonas Chickering (1797-1853) of Boston, who applied it to the grand piano as well as to the square, and brought the principle up to a high degree of perfection—establishing by it the independent construction of the American pianoforte.

We have next to do with over-or cross-stringing, by which the bass division of the strings is made to cross over the tenor part of the scale in a single, double or treble disposition at diverging angles—the object being in the first instance to get longer bass strings than are attainable in a parallel scale, and in the next to open out the scale and extend the area of bridge pressure on the sound-board. In the 18th century claveichords were sometimes overstrung in the lowest octave to get a clearer tone in that very indistinct part of the instrument (strings tuned an octave higher being employed). The first suggestion for the overstringing in the piano was made by the celebrated flute-player and inventor Theobald Boehm, who carried it beyond theory in London, in 1831, by employing a small firm located in Cheapside, Gericke & Wolf, to make some overstrung pianos for him. Boehm expected to gain in tone; Pape, an ingenious mechanician in Paris, tried a like experiment to gain economy in dimensions, his notion being to supply the best piano possible with the least outlay of means. Tomkinson in London continued Pape's model, but neither Boehm's nor Pape's took permanent root. The Great Exhibition of 1851 contained a grand piano, made by Litchehenthal of St Petersburg, overstrung in order to gain symmetry by two angle sides to the case. It was regarded as a curiosity only. Later, in 1855, Henry Engelhard Steinway (originally Steinweg; 1797-1871), who had emigrated from Brunswick to New York in 1849, and had established the firm of Steinway & Sons in 1853 in that city, effected the combination of an overstrung scale with the American iron frame, which exhibited in grand and square instruments shown in London in the International Exhibition of 1862, excited the attention of European pianoforte makers, leading ultimately to important results. The Chickering firm claim to have anticipated the Steinways in this invention. They assert that Jonas Chickering had begun a square piano on this combined system in 1853, but, he died before it was completed, and it was brought out later. It is often difficult to adjudicate upon the claims of inventors, so rarely is an invention the product of one man's mind alone. However, the principle was taken up and generally adopted in America and Germany, and found followers elsewhere, not only in grand but in upright pianos, to the manufacture of which it gave, and particularly in Germany, a powerful impetus.

**Fig. 32.—Meyer's Metal Frame for a Square Piano, 1833.**

In a single casting:

**Fig. 33.—Steinway's Grand Piano, 1884.**

Metal framing in a single casting and overstrung.

Since 1885 the American system of a metal plate in one casting, and cross- or over-stringing by which the spun bass strings cross the longer steel diagonally, has become general in Europe with the exception of France, where the musical taste has remained constant to the older wooden structure and parallel stringing throughout. The greater tenacity of the modern cast-steel wire favours a very much higher tension, and consequent easier production of the higher partials of the notes, permitting a *sostenuto* unknown to Beethoven, Schumann or Chopin. While in 1862 the highest tension of a concert grand piano worked out at sixteen tons, since 1885 thirty tons has been recorded. Generally speaking, the rise in tension may be expressed musically by the interval of a minor third, to the great advantage of the standing in tune. First shown by Henry Steinway in the London Exhibition of 1862, this altered construction attracted extraordinary attention at Paris in 1867, and determined the German direction of manufacture and a few years later the English. What is now particularly noticeable wherever pianos are made is the higher average of excellence attained in making, as well as in pianoplaying. Naturally the artistic quality, the personal note, characterizes all first-class instruments, and permits that liberty of choice which appertains to a true conception of art.

Much attention has been given of late years to the touch of pianos, to make it less tiring for the modern performer, especially since, in 1885-1886, Anton Rubinstein went through the herculean feat of seven consecutive historical recitals, repeated in the capital cities and principal musical centres of Europe. For even this stupendous player a light touch was indispensable. In
the competition for power piano makers had been gradually increasing the weight of touch to be overcome by the finger, until to obtain the faintest pianissimo from middle C, at the front edge of the key, from three to four ounces was a not uncommon weight. The Broadwood grand piano which Chopin used for his recitals in London and Manchester in 1848, an instrument that has never been repaired or altered, shows the resistance he required: the middle C sounds at two ounces and a half, and to that weight piano-makers have returned, regarding two ounces and three-quarters as a possible maximum. Owing to the greater substance of the hammers in the bass, the touch will always be heavier in that department, and lighter in the treble from the lesser weight. In balancing the keys, allowance has to be made for the shorter leverage of the black keys. When the player touches the keys farther back the leverage is proportionately shortened and the weight increased, and there is also an ascending scale in the weight of the player's blow or pressure from pianissimo to fortissimo. The sum of the aggregate force expended by a pianist in a recital of an hour and a half's duration, if calculated, would be astonishing.

The most important structural change in pianos in recent years has been the rejection of support given by metal bars or struts between the metal plate to which the strings are hitched and the wrest-plank wherein the tuning-pins are inserted. These bars formed part of William Allen's invention, brought forward by Stodart in 1820, and were first employed for rigidity in place of compensation by the Paris Erards two years later, Broadwood in London introducing about that time the fixed metal plate. The patent No. 1231, for the barless or open-scale piano, taken out in London in 1888 by H. J. Tschudi Broadwood, is remarkable for simplification of design as well as other qualities. Ten years elapsed after the taking out of the patent before the first barless grand was heard in public (January 1898 at St James's Hall). The metal frame, bolted in the usual manner to the bottom framing, is of fine cast steel entirely free from any transverse bars or struts, being instead turned up round the edges to form a continuous flange, which enables the frame to bear the increased modern tension while providing additional elasticity and equality of vibration power throughout the scaling. The absence of barring and bracing tends to subdue the metallic quality of tone so often observable in pianofortes constructed with heavy iron frames, and the barless steel frame being so much more elastic than the latter, no loss in resonance is perceptible. The tone of the barless grand is of singular beauty and sonority and is even throughout the compass.

The problem of resonance—with stringed keyboard instruments, the reinforcement or amplification of sound—has, from the days of the lute- and spinet-makers, been empirical. With lute, guitar, and viol or violin the sound-box comes in, combining in the instrument the distinct properties of string and enclosed air or wind. With the spinet, harpsichord and piano we have to do chiefly with the plate of elastic wood, to amplify the initial sound of the strings; and the old plan of a thin plate of spruce, put in slightly convex and with an under-barring of wood for tension, has absorbed the attention of piano-makers. The violin belly, with its bass bar and sound post, has relation to it; but the recent invention of the Stroh violin has shown that the initial string vibrations may be passed through a bridge, be concentrated, and adequately transferred to an aluminium disk not much larger than half a crown. The piano, with its numerous strings, cannot be so reduced, but the reinforcement problem is open to another solution, tentative it is true, but a possible rival. The "Gladiator" soundboard is the invention of Albert Schulz, late director of the piano manufactory of Ritmüler and Söhne of Göttingen. Dr Moser's name has been associated with the inventor's in the English patent. In the "Gladiator" two slabs of wood, with grain of opposed direction to give the necessary tension, are glued together, and the whole system of belly bars is done away with. There is a thinning round the edge, to facilitate promptness of speech. As we are still feeling our way towards a well-considered and comprehensive statement of resonance, this invention is one claiming scientific interest, as well as being of possible practical importance.

To return to the touch. The desirability of what is called repetition—that the jack or sticker, which from the depression of the key delivers the blow that raises the hammer to the strings, should never be far away from the notch or nose which receives the impulse—is as much an object of consideration with pianomakers now as it has been since Sebastian Erard began those experiments in 1808 which ended...
in his famous "double escapement" action. The principle of this grand action, like that of Wornum patented for upright pianos in 1826, has become general. But Joseph Henry Cary in 1853 (patent No. 2183) invented a simple contrivance for repetition in all pianos, neglected at the time, and subsequently repatented and disputed over by others, which has only been preserved in the records of the patent office, while the inventor has left no other mark. But the utility of the invention has come to light. It is increasingly used in the actions of upright pianos, and, in combination with the old English grand action, is successfully competing with the Erard action proper and the simplified Herz-Erard, of late years so very generally employed.

There has been a great change in the freer technique of pianoplaying, partly favoured by the development of piano-making, but reacting and obliging the pianomakers to keep their attention incessantly alive to the aim and requirements of the players. It is true that the genius of Beethoven dominates a technique that has become obsolete, and so completely that the adequate performance of his piano works still gives to the sense as well as the intellect the highest pleasure, but his annotations to Cramer's Studien, as preserved by Schindler, betray the close touch of the claveichord-player and the student of C. F. E. Bach's Essay on Clavichord-Playing, as well as the weakness as a musical instrument of the early piano. The inventor of a technique so original, and at the time (c. 1830) so extraordinary, as Chopin's, sat at the piano with his elbows immovable, using, for flexibility, neither wrist nor arm. With Chopin, to play loudly was anathema. The modern free style of playing comes from CZerny—whom Liszt to Beethoven despised as having no legato (Bindung)—through Liszt to the Rubinstein, and to the splendidly equipped performers of our time, to whom the pedal has become indispensable for cantabile and effect.

The most expert performers are now rivalled technically by the recent extraordinary invasion of the American automatic piano-players—the Angelus, Pianola, Apollo, Cécilian, and other varieties of the same idea. The use of the perforated roll acts by means of the ingenious and indeed faultless application of pneumatic leverage to the ordinary piano, doing duty for the pianist's fingers; and it is made possible to play louder or softer, faster or slower, by mechanical arrangement. Such an instrument lacks the player's touch, which is as personal and indispensable for sympathy as the singer's voice. Still, to a violinist, it is made possible to have a correct condutor in a Beethoven or Brahms sonata with one of these handy companions, just as it is to a singer to have always at command the accompaniments to his or her repertory. The Apollo has the addition of a useful transposing apparatus—an aid, however, that, though often tried, has never yet been adopted; it is possibly too disturbing to the musician's ear. The mechanical tuning-pin is an analogous experiment which comes regularly under notice as the years go by, to be as persistently rejected. The most practical of these tuning-inventions was the Alibert, shown in the Inventions Exhibition, 1885. Here, pressure upon the strings above the wrest-plank bridge modified their tension after a first rough adjustment to pitch had been effected.

The perforated music-sheet, a mechanism common to pianoplays, is well shown in a diagram that appears in a French patent, 1842. A United States patent for a keyboard piano-player was issued to E. D. Bootman (Dec. 18, 1866), and the first pneumatic keyboard piano-player was patented in France in 1862 by M. Foreman. Between 1879 and 1902, a total of 55 patents had been issued in the States. The first complete automatic piano-player ready for performance was the Angelus (No. 21799, 1897). The specification is from a communication to the British patent office by Edward Hollingworth, White, of Meriden, New Haven county, Conn. There is a spring chest, fulcrum bar, finger levers, bellows and pedals. The whole apparatus is contained in a portable cabinet mounted upon castors, so as to be conveniently moved about a room. The finger levers or key strikers connected to a manual key-roller portion of the manual clavier of a piano. Thus the automatic piano-player comprises a portable cabinet provided with bellows and operating pedals, a pneumatic actuating mechanism, a tracker adjusted for the use of a perforated music-roll. Pianola, there is in mind that the miniature keyboard was capable of accelerating or retarding the tempo at the will of the operator. A roll of music, 12 in. wide and varying in length according to the composition, can be placed in position promptly, and when exhausted can be replaced by another roll, a simple step, altogether a triumph of mechanical adjustment. The Angelus followed in 1898, the Apollo 1900. The difference of all these clever contrivances is not conspicuous to the amateur.

These tickets for the cover of this book with a substitute for touch and the necessity for the persevering acquirement of a difficult technique, another, the Virgil Practice Clavier, so called after the inventor, Mr Almon Kinsdale Virgil, an American musician, is intended to shorten the period of study by doing away with tone, so that the finger technique is acquired mechanically and unemusically, while value of tone, reading, expression, whatever we understand by musical production exciting our response through the ear, is delayed until the hand is formed and considerably developed. The opinion of some of the very greatest pianists is brought forward as approving of the system; in the work, for instance, of Vladimir de Pachmann, whose technique was formed long before the Virgil Clavier came into use, the touch of a concert piano is not likely to exceed three and a half ounces it is hardly likely that these skilled performers use this dumb keyboard with the graduated weight advised for advancing
pupils, namely, from five to eight ounces. It is allowed that the lightest possible touch may be used at first. One high recommendation certainly remains after all that may be said regarding Mr Virgil's invention: that it is practically silent, which also clicks that the duration of finger attachment being alone audible, a boon to the unwilling hearers of ordinary piano practice, scales and five-finger exercises. Mr Virgil's invention was produced in its elementary form in 1872, the more satisfactory Practice Clavier dates from the beginning of the century, about 1890. It was brought to England in 1895 by Mr Virgil.

PIANOSA (anc. Planiasia), an island of Italy, belonging to the province of Lepanto, and forming part of the commune of Marciana (Elba), from which it is 73 m. S.W. Pop. (1881), 770. As its name indicates, it is quite flat, and the highest point is only 95 ft. above sea-level. Its area is 6 sq. m. Augustus banished it to his grandson, Agrippa Postumus, and some ruins of baths near the harbour still bear his name. It changed hands more than once in the wars between Pisa and Genoa in the 13th and 14th centuries; from 1350 it belonged to the prince of Piombino, but was depopulated in 1553 by the Turkish fleet, and only resettled at the beginning of the 19th century. In 1857 a penal colony was established here.

PIARISTS, the popular name of a Catholic educational order, the "cleric regulares scholarum piarium," the Pauline Congregation of the Mother of God, founded by Joseph Calasanz (Josephus a Matre Dei) at Rome in the beginning of the 17th century. A native of Calasanz in the province of Huesca in Aragon, was born on September 11, 1536, studied at Lerida and Alcalá, and after his ordination to the priesthood removed to Rome (1592). Here he organized, in 1607, a brotherhood which ultimately, in 1617, became an independent Congregation, numbering at that time fifteen priests, under Calasanz as their head. To the three usual vows they added a fourth, that of poverty. The Congregation received a new constitution from Gregory XV, and had all the privileges of the mendicant orders conferred upon it, Calasanz being recognized as general. In 1643 the jealousy of the Jesuits led to his removal from office; owing to the same cause the Congregation was deprived of its privileges by Innocent X. in 1646. Calasanz, who died on August 22, 1648, was beatified in 1748, and canonized in 1767. The privileges of the Congregation were successively restored in 1660, 1660 and 1668. The Piarists, who are not numerous, are found chiefly in Italy, Spain, the West Indies, Germany, and especially in Austria-Hungary. Before the course of study was regulated by the state, a Piarist establishment contained nine classes: reading, writing, elementary mathematics, schola parva or Rudimentorum, schola Principiorum, Grammatica, Syntaxis, Humanitas or Poesis, Rhetorica. The general provost of the order is chosen by the general chapter, and with a general procurator and four assistants resides at Rome. The members are divided into professors, novices, and lay brethren. Their address is very similar to that of the Jesuits; their motto "Ad majus pietatis incrementum!".

Martin, Ordens- und Kongregation (Munich, 1892) ii. 271; articles by O. Zöckler in Herzog-Hauck's Realencyklopädie für protestantische Theologie (1904), vol. xv. and C. Klein in Wetzer and Weite’s Kirchen-lectzion (1893), vol. ix.

PIATRA (Piatra), the capital of the department of Neamtuz, Rumania, situated on the left bank of the river Bistrita, where it cuts a way through the Carpathian foothills. Pop. (1900), 17,391. A branch railway passes through the town, and at Bacu meets the main line from Cernovicki to Galatz. The Roman Catholic parish church was founded in 1407 by Stephen the Great. There are saw-mills and textile factories in Piatra, which has a considerable trade in wine and timber. Neamtuz is one of the most densely forested regions in Moldavia. Lumber rafts are floated down the Bistrita to the Sereth, and so on to Galatz. There are several monasteries in the neighbourhood.

PIATTI, CARLO ALFREDO (1822–1901), Italian violoncellist, was born at Bergamo on the 8th of January, 1822. He was the son of a violinist, and became a pupil at the conservatorio of Milan. From 1838 onwards he journeyed over Europe, playing with extraordinary success in all the important cities of the continent. In 1844 he appeared before the London public at a Philharmonic Concert; and in 1859, on the foundation of the Popular Concerts, he took up the work with which he was most intimately connected for thirty-nine seasons, retaining until 1897 the post of first violoncello at these famous chamber concerts, during the latter
PIAUHY—PICA

half of each series. His purely classical style, his wide musical sympathies, and his general culture and charm, would have ensured him a high position even without his marvellously finished technical skill. In 1804 the fiftieth anniversary of his first appearance in London was celebrated by a reception given in honour of him and his lifelong friend Joachim. He retired from public life, owing to a severe illness, in 1807, and until his death at Bergamo on the 10th of July 1810 divided his time between his native town and Cadenabbia. As a composer he attained a wide popularity with some graceful and popular songs; he did excellent work as an editor; and he was an enthusiastic collector and musical antiquary.

PIAUHY, or PIAUHI, a north-eastern state of Brazil, bounded N. and W. by Maranhão, E. by Ceará, Pernambuco and Bahia, and S. by Bahia. It has a few miles of Atlantic coast-line on the N., and the Rio Parnahyba forms the boundary line with Maranhão throughout its entire length. Area, 110,523 sq. m.; pop. (1900), 334,338. Part of the state on the Atlantic coast and along the lower Parnahyba is low, swampy and malarial. South of this the country rises gradually to a high plateau with open campos. This plateau region is watered by numerous tributaries of the Parnahyba, chief of which are the Urussuhy, the Canindé and its tributaries, and the Rio Piraí, which rises in the Parahim, which drains the large inland lake of Parnahyba, the Longa, and the Poty, which has its source in the state of Ceará. The Parnahyba is navigable for boats of 3 ft. draught up to Nova York, a few miles above the mouth of the Guarneja, and could be made navigable up to the mouth of the Balsas. The climate is hot and humid in the lowlands and along the lower Parnahyba, but in the uplands it is dry with high sun temperatures and cool nights. The principal industry is stock-raising, which dates from the first settlement in 1674 by Domingos Affonso Mafrense, who established here a large number of cattle ranges. A secondary industry is the raising of goats, which are able to stand neglect and a scanty food supply. Sheep have likewise been raised in Piauhy, but there is no market for mutton and their wool is not utilized. The agricultural products are cotton, sugar and tobacco. Of food-stuffs the people do not produce enough for their own consumption. Forest products include rubber, carnauba wax and dyewoods. The exports include hides, skins, rubber, wax, tobacco and cotton. The canindé and its tributaries are navigable for light draught above Parnahyba (town), with which it is connected by a line of light-draught river boats. The town dates from 1852, is attractively situated, and is regularly laid out with broad, straight streets crossing each other at right angles. The population of the município in 1890 was 31,523, which includes a large rural district. Other towns, with their populations in 1890, are: Oeiras (19,858), founded in 1778 under the name of Moxa; Amarante (15,525); Valença (17,503); and Campo Maior (12,425), the figures given of population being those of the large districts (municípios) in which the towns are situated.

PIAZZA, properly an open square or place in an Italian town (Ital. piazza, from Lat. platea, broad space, Gr. παρτές, broad). These squares were usually surrounded with a colonnade or arcade, and thus the word has been loosely applied to a covered walk or arcade along the front of a building, and in America, to the veranda of a house.

PIAZZA ARMERINA, a city of Sicily, in the province of Caltanissetta, 30 m. by road E.S.E. from that town, and the distance of the railway station of Assoro-Valguarnera, 43 m. W. of Catania, situated 2560 ft. above sea level. Pop. (1901), 24,110. It has a 15th-century cathedral, with a fine campanile, and some of the houses show Norman or Gothic architecture. The foundation of the town dates from the 11th century, and the dialect is Lombard.

See Mauceri in L’Arte (1906), 14.

PIAZZI, GIUSEPPE (1746-1810), Italian astronomer, was born at Ponte, in the Valtellina, on the 16th of July 1746. He entered the Theatine Order in 1704, accepted the chair of mathematics in the academy of Palermo in 1780, and persuaded the viceroy, Prince Caramanico, to build an observatory there.

During a visit to England in 1788 he procured from Jesse Ramsden a five-foot altazimuth, with which he collected at Palermo, 1792-1813, the materials for two admirable star-catalogues, published in 1803 and 1814 respectively. While engaged on this work he discovered, on the 1st of January 1801, the first asteroid or minor planet, to which he gave the name of Ceres, the tutelary deity of Sicily. He died at Naples on the 22nd of July 1826.

PIBRAC, GUY DU FAUR, SEIGNEUR DE (1529-1584), French jurist and poet, was born at Toulouse, of an old family of the magistracy. He studied law there with Jacques Cujas, and afterwards at Pau. In 1548 he was admitted to the bar at Toulouse, at once took high rank, and rose to be juge-mage, an office in Languedocian cities about equal to that of prévôt. He was selected in 1562 as one of the three representatives of the king of France at the council of Trent. In 1563 he became general advocate to the parlement of Paris, and entered the renaissance in justice, which was almost corrupt under French justice.

In 1573 he was sent by Charles IX. to accompany as chancellor his brother Henry (afterwards Henry III.) to Poland, of which country he had been elected king. Pibrac’s fluent Latin won much applause from the Poles, but his second visit to Poland in 1575, when sent back by Henry III. to try to save the Crown he had deserted, was not so successful. Then he was employed in negotiations with the so-called politiques, and he managed to keep them quiet for a while. In 1578 he became the chancellor of Marguerite of France, queen of Navarre. Although he was fifty, her beauty and intellectual gifts led him to aspire to win her affection; but he was rejected with disdain. He died in 1584. His oratorical style was too pedantic, but quotations from the classics had a fresher meaning in his day. He was the friend of Ronsard, de Thou and L’Hôpital, and left, among other literary remains, elegant and sentimentals quatraines.

PIBROCH, a form of music as played by the bagpipe. The word is derived from the Gaelic pibb-reacht, the art of the bagpiper. This special form of bagpipe music, consisting of theBC of the bagpipe, is played by players of the bagpipe. These variations are generally of a martial or warlike character and include dirges and marches (see BAGPIPE).

PICA, the name of the European representative of a group of diminutive rodent mammals, also known as tailless hares, mouse-hares, or piping hares, constituting the family Ochotonidae with the single genus Ochotona. From the more typical hares and rabbits they differ by the short and rounded ears, the absence of a tail, and the relatively shorter hind-limbs, as well as by complete collar-bones. The soles of the feet are hairy, and the fur is usually soft and thick; while in some cases the last upper molar is absent. Picas are inhabitants of cold and desert regions. They dwell either in the chinks between rocks, or in burrows, although some Himalayan species frequents pine-forests. They are very active, and most of the species utter a piping or whistling cry. They store up a supply of grass for winter use; in Siberia it is stacked in small heaps. The Himalayan Ochotona roylei may be seen in the daytime, but most kinds are nocturnal. The Siberian species, O. alpina, ranges into eastern Europe, but at Rozhdestvensk is the headquarters, although a few species range into Arctic America and the Rocky Mountains. In size picae are compared to guinea-pigs. Till of late years the group has been generally known by the name of Lagomys. There are several extinct genera.

PICA, the Latin name of a genus of oscine passerine birds, the magpies. The Latin word, by interchange of initial $p$ and $k$, is possibly the Gr. καίρα (see MAGPIE), and probably the same word as picus, the woodpecker (q.v.). Another derivation would connect both pica and picus with the root píca of pingue, to
paint, from the parti-colored appearance of the bird. It is this “pied” or black and white look of the page that probably gave the name of pica, “pie” or “pige,” to the ordinal printed in black-letter (see PIGE), and thence to a size of type in printing coming next to “English” (see TYPOGRAPHY). The Gr. kíssa and Lat. pica were used of a perverted craving for unnatural foods; and the word has been adopted in this sense in modern medical terminology.

PICARD, LOUIS JOSEPH ERNEST (1821-1877), French politician, was born in Paris on the 24th of December 1821. After taking his doctorate in law in 1846 he joined the Parisian bar. Elected to the corps législatif in 1858, he joined the group of Émile Ollivier. But as Ollivier approximated to the government standpoint, Picard, one of the members of the group known as Les Cinq, veered more to the left. He founded in 1868 a weekly democratic journal, L’Électeur libre, and in 1869 was elected both for Héroult and Paris, elective to sit for the former. From the 4th of September 1870 he held the portfolio of finance in the government of National Defence. In January 1871 he accompanied Jules Favre to Versailles to arrange the capitulation of Paris, and in the next month he became minister of the interior in Thiers’s cabinet. Attacked both by the Monarchist and the Republican press, he resigned in May. Later in the year he was sent as ambassador to Brussels, where he remained for two years. On his return to Paris he resumed his seat in the Left centre, and in 1875 became life senator. He died in Paris on the 13th of May 1877.

PICARDY (La Picardie), one of the old provinces of France, bounded on the N. by Hainaut and Artois, on the E. by Champagne, on the S. by the Ile de France, and on the W. by Normandy and the English Channel. Its maritime frontier ran from the mouth of the Aa to the cliffs of Caux, and it included the whole of the basin of the Somme and part of that of the Oise. The chief towns of Picardy were Amiens, Boulogne, Abbeville, Laon, Soissons, Montreuil, Péronne, Beauvais, Montdidier, St Quentin and Noyon. Its principal rivers were the Somme and the Oise. Picardy formed part of the archdiocese of Reims, and its bishops were Amiens, Beauvais, Sens, Soissons, Noyon and Laon. In 1789 the province of Picardy was covered by the three bishoprics of Amiens, Noyon and Boulogne. It was one of the provinces of the five great fermes, districts subject to the tariff of 1664, and in judicial matters was under the authority of the parlement of Paris. Its area now forms the department of the Somme and parts of the departments of Pas de Calais, Aisne and Oise. It was not formally separated from the north of France until the 15th century, but was employed by Matthew Paris and was in general use in the 13th century. In the 13th century the province was divided into the two bailliages of Amiens and Vermandois, but its regular organization as part of the kingdom of France only dates from the beginning of the 16th century. At this time it was divided into north and south Picardy. North Picardy, or Picardy proper, formed one of the great military governorships of the kingdom, while south Picardy was included in the Ile de France. North Picardy was divided into upper and lower Picardy, the former being the interior part of the province and the latter the district along the coast. Upper Picardy comprised the districts of Amiènois, Santier, Vermandois and Thière, and lower Picardy those of Ponthieu, Vimeu, Boulognais and Calaisis, or the Pays romains. South Picardy included the districts of Beauvaisis, Laonais and Soissons.

Under the Romans Picardy was part of Belgica secunda; it was inhabited by the Morini, the Ambiani, the Vermandii, the Bellovaci and the Suessiones, whose names still appear in Amiens, Vermandois, Beauvais and Soissons. The Romans intersected the district with roads and built several castra to defend the valley of the Somme. In the 3rd century Christianity was preached here, and St Quentin and others were martyred. A little later abbeys were founded, among them Corbie, St Valéry and St Riquier. Early in the 5th century Picardy became the centre of Merovingian France, for, as the historian Michelet says, “l’histoire de l’antique France semble entassée en Picardie.” Clovis had his first capital at Soissons. Châlons had his at Noyon, and Laon was the capital and the refuge of the later and feebler Carolingian sovereigns.

During the later feudal period Picardy was the home of the counts of Vermandois, of Clermont and of Pontchic, the sire of Coucy and others. The neighbouring dukes of Burgundy cast covetous eyes upon the province; in 1435, by the famous treaty of Arras, the royal towns and lands in the valley of the Somme were ceded by King Charles VII. to Burgundy. However, after the death of Charles the Bold in 1477 Picardy was finally united with the crown of France. The province was early an industrial district. Flemish immigrants brought with them the lucrative trade of weaving cloth, and the Somme towns were soon competing with those of Flanders. The Picard towns were noted for their love of independence, which often brought them into collision with the kings of France during the 13th century. At a later time the province received a number of Spanish immigants. In the middle ages the Picards formed one of the four “nations” at the university of Paris. Picardy has a high place as a home of Gothic art, this being testified to by the superb cathedrals at Amiens and Noyon, while within its borders is the famous château de Coucy.

Picardy has a literature of its own, which was rich and popular in the 12th century. It suffered greatly from the ravages of the Normans, and later during the Hundred Years’ War and the wars between France and Spain. Within it are the famous fields of Agincourt, Agincourt and St Quentin, while it also includes places of conference like Guines, Amiens and Picquigny. The Picard had a high reputation as a soldier, being sometimes called the “Gascon of the North,” and in 1358 Henry II. created the régiment de Picardie. Many anthropological remains have been found in the Somme valley.

See Labourt. Essai sur l’origine des villes de Picardie (Amiens, 1840); Gourrier. Introduction à l’histoire générale de la province de Picardie (Amiens, 1850); and H. Carnoy, Littérature orale de la Picardie (1885).

PICARESQUE NOVEL. This special form of the roman d’aventures may be defined as the prose autobiography of a real or fictitious personage who describes his experiences as a social parasite, and who satirizes the society which he has exploited. The picaron, or rogue type, is represented by Encolpous, Ascarlos and Giron in the Saltycon which tradition ascribes to Petronius; it persists in Lucian, in the Roman de Renart, in the fabliaux, and in other works popular during the middle ages, and it is incarnated in real life by such men of letters as the Archpriest of Hita and Francois Villon. But in its final form the picarons novel may be regarded as a Spanish invention. The word picaresco is first used, apparently, in a letter written by Eugenio de Salazar to Toledo on the 15th of April 1560; the etymology which derives picaresco from picaro (to pick up) is unsatisfactory to philologists, but it suggests the picarons chief business in life. In the Tesoro de la lengua castellana (Madrid, 1611) Sebastian Covarrubias y Orozco, the best of Spanish lexicographers, describes a picaro as a man of loose character engaged in menial work and—by extension—a rascal who attains his ends by skilful dissimulation; and the earliest application of the expression picaro to a character in fiction occurs in Mateo Alemán’s Guzmán de Alfarache, the first part of which was published in 1599. But a genuine novela picaresca existed in Spain before the word picaros became generally current.

The earliest specimen of the kind is La Vida de Lazarillo de Tormes y de sus fortunas y adversidades, an anonymous tale long attributed, on insufficient grounds, to Diego Hurtado de Mendoza (q.v.). The authorship of this brilliant book and the circumstances of its publication are obscure; however, it was certainly issued not later than 1554, and was thrice reprinted before 1559, when it was placed on the Index. Imitations of so successful a story were inevitable, and so early as 1555 there appeared at Antwerp La Segunda parte de Lazarillo de Tormes, an anonymous sequel which completely misinterpreted the irreverent wit of the original. The first part had been prohibited because of its attacks on the
clergy; in the second part the hero is presented as a devout youth transformed into a tunny at the intercession of the Virgin Mary, who thus saved him from death; after many extravagant experiences in this form he is restored to human shape, and proposes to teach the submarine language at the university of Salamanca. This dull performance naturally failed to please and, meanwhile, many surreptitious copies of the first part were introduced into Spain; the Inquisition finally gave up the attempt to suppress it, and in 1573 an expurgated edition was authorized. With this mutilated version the Spanish public was forced to be content during the remaining fifteen years of Philip II.'s reign. Upon the death of this sombre monarch society relaxed its hypocritical pose of austerity, and in 1599 Mateo Alemán (q.v.) published the Primera parte de Guzmán de Alfarache. It is modelled upon Lazarillo de Tormes, being the autobiography of the son of a ruined money-lender; but the writer indulges in a tedious series of moralizations. This contrasts sharply with the laconic cynicism of Lazarillo de Tormes; but Guzmán de Alfarache is richer in invention, in variety of episode and in the presentation of character. Its extraordinary popularity tempted a Valencian lawyer named Juan José Martí to publish a Segunda parte de la vida del pícaro Guzmán de Alfarache (1602) under the pseudonym of Mateo Luján de Sayavedra. Though partly plagiarized from the manuscript of the genuine second part to which Martí had somehow obtained access, the continuation was coldly received; in 1604 Alemán brought out the true continuation, and revenged himself by introducing into the narrative a brother of Martí—a crazy picaroon of the lowest morality who ultimately commits suicide in disgust at his own turpitude. In Lazarillo de Tormes, and still more in Guzmán de Alfarache, it is difficult to distinguish between the invented episodes and the personal reminiscences of the authors. The Viage entretenido (1605) of Agustín de Rojas is a realistic account of the writer's experiences as a strolling actor and playwright, and, apart from its considerable literary merits, it is an invaluable contribution to the history of the Spanish stage as well as a graphic record of contemporary low life; the chief character in the book is called el caballero del milagro, an expression which recurs in Spanish literature as the equivalent of a chevalier d'industrie.

The next in chronological order of the Spanish picaresque tales is La Picara Justina (1605), the history of a woman picaroon, which has long been customary to ascribe to Andrés Pérez, a Dominican monk; there is, however, no good reason to suppose that the name of Froch–1615), is a similarly vivid sketch of the Spanish rogue, and in the comedy entitled Pedro de Urdemalas Cervantes again presents a brilliant panorama of picaresque existence. He returns to the subject in Rinconete y Cortadillo and in the Coloquio de los perros, two of the best stories in the Novelas ejemplares (1613). The attraction of picaresque life was felt by pious and learned critics, and expounded in print. In the Viage del mundo (1614) the zealous missionary Pedro de Cevallos interpolates amusing tales of what befell him in the slums of Andalusia before he fled from justice to America, where he lived as a sinful soldier till his spiritual conversion was accomplished. Cristóbal Suárez de Figueroa, a caustic critic of his contemporaries and an arbitre of taste, did not think it beneath his dignity to show a disconcerting acquaintance with the ways of professional rogues, and in El Pasagero (1617) he fills in the sketch of the knavish inn-keeper already outlined by Cervantes in Don Quixote. Evidence of the widely diffused taste for picaresque literature is found in Enríquez de Castro (1617), an interminable story written in Spanish by a Frenchman named François Loubayssin de Lamerca, who brought out his book at Paris; two years previously Loubayssin had introduced some clever but risky picaresque episodes in his Engaños deste siglo y historia sucedida en nuestros tiempos. But his attempt to fill a larger canvas is a complete failure.

The roving instinct of Vicente Martínez Espinol (q.v.) had led him into strange and dangerous company before and after his ordination as a priest, and a great part of his Relaciones de la vida del escudero Marcos de Obregón (1618) is manifestly the confession of one who has regretfully outlived his pleasant vices. The baffling compound of truth with fiction and the lucid style of which Espinol was a master would suffice to win for Marcos de Obregón a permanent place in the history of Spanish literature; the fact that it was largely utilized by Le Sage in Gil Blas has won for it a place in the history of comparative literature. Within five months of its publication at Madrid a fragmentary French version by the Sieur d' Audigier was issued at Paris, and at Paris also there appeared a Spanish picaresque story entitled La Desordenada codicia de los bienes ajenos (1619), ascribed conjecturally to a certain Dr Carlos Garcia, who reports his conversation with a gargantuan gaol-bird, and adds a glossary of slang terms used by the confraternity of thieves; he was not, however, the first worker in this field, for a key to their gross jargon had been given ten years previously by Juan Hidalgo in his Romanes de germains (1609), a series of gypsie ballads. Every kind of picaresque is portrayed with intelligent sympathy by Alonso Jerónimo de Salas Barbabellido, who is always described as a picaresque novelist; yet he so constantly neglects the recognized conventions of the Spanish school that his right to the title is disputable. Thus in La Hija de Celestina (1612) he abandons the autobiographical form, in El Subtil coroló Pedr De Urdemalas (1620) he alternates between dialogue and verse, and in El Necio bien afortunado (1621) the chief character is rather a cunning dolt than a successful scoundrel. The pretence of warning newcomers against the innumerable occasions of sin in the capital is solemnly kept up by Antonio Lihan y Verdugo in his Guía y avisos de forasteros que vienen a la corte (1620), but in most of his tales there is more entertainment than decorum.

The profession of a serious moral purpose on the part of many picaresque writers is the more surprising in view of the licence and excuse for the introduction of unsavoury incident. There is, however, no ground for doubting the sincerity of the physician Jerónimo de Alcalá Yañez y Ribera, who at one time thought of taking holy orders, and studied theology under St John of the Cross. An unusual gravity of intention is visible in Alonso, moto de muchos amos (1624–1625), in which the repentant pícaro Alonso, now a lay-brother, tells the story of his past life to the superior of the monastery in which he has taken refuge. It abounds with pointed anecdotes and with curious information concerning the Spanish gypsies, and this last characteristic explains George Borrow's hyperbolical praise of the work as competing with Don Quixote in grave humour, and as unequalled for knowledge of the human mind and acute observation.

The novel of Alonso de Contreras, an ex-nunn named Catalina de Erazno, who fled from her convent, dressed herself in men's clothes, enlisted, was promoted ensign, and saw more of life than any other nun in history. Broadsides relating the story of this picaresque amazon were circulated during her lifetime, and the details of her adventures aroused the attention of De Quincey, who would seem to have read them in a Spanish original which has been admirably translated since then by the French poet José María de Heredia. The Spanish original, in its existing form, was issued no earlier than 1859 by Joaquín María de Ferrer, whose character is not a satisfactory guarantee of the work's authenticity; but its interest is unquestionable. No such suspicion attaches to the Vida de Alonso de Contreras, first published in 1895; this out-at-elbows soldier faithfully records how he became a knight of the Order of Santiago, how he
broke all the Commandments, how he found himself stranded in Madrid, how his fine air captivated Lope de Vega, who housed him for eight months and dedicated to him a play entitled Rey sin reino, and how the ex-caption ended by "resolving to retire to a lonely spot and there serve God as a hermit." Every convention of the picaresque novel is faithfully observed, and the incidents are no doubt substantially true, though Contreras, like most converts, judges his own past with unnecessary harshness. This subtle form of vanity also pervades the Comentarios del desen- gañado de sí mismo of Diego duque de Estrada, a rakish soldier and inferior dramatist whose autobiography (begun in 1614 and continued at intervals during many years) was not printed till 1860. A far higher order of talent distinguishes the Capitulaciones de la vida de la corte y oficios entretenidos en ella, a bitterly unsparing review of picaresque life written by the great satirist Francisco Gomez de Quevedo y Villegas (q.v.). These thumbnail sketches were the preparatory studies worked up into the more elaborate Vida del buen Don Pablo (1626), the cleverest and most revolting book of its class. There is no attempt to scar the wicked by means of awful examples; the moral lesson is contemptuously thrown aside; the veil of romance is rent in twain, and the pico— the niphew of the public executioner—is revealed as he is, gloating in cruelty and reveling in the conscious enjoyment of crime. But though Quevedo detests mankind, his morose vision of existence rarely degenerates into caricature. In his repugnant, misanthropic masterpiece the sordid genius of the Spanish picacon finds absolute expression. Nothing further remained to be done in the matter of realism; henceforth the taste for picaresque novels grew less keen, and later writers unconsciously began to humanize their personages.

The Varia fortuna del soldado Pindaro (1626) added nothing to the established reputation of Gonzalo Cispedes y Menezes. A clever anonymous story, Don Rainaldo el enterentido (1627), missed fire, even though it was attributed to Quevedo; yet the author, Diego Tovar y Valderrama, compiled a sprightly diary of the events which make up a picacon's crowded day, and failed solely because the interest in rogues was waning. Other writers of undoubted gifts were slow to see that the fashion had changed. Alonso de Castillo Solórzano (q.v.) tempted the public with three picaresque stories published in quick succession: La Niña de los embustes, Teresa de Manzanares (1634), the Aventuras del Bachiller Trapasa (1637) and a sequel to the latter entitled La Garduna de Sevilla (1642). Clever as Castillo Solórzano's stories are, their tricky heroes and heroines were no longer welcomed with the old enthusiasm in Spain; the Bachiller Trapasa was destined to be continued by Mateo da Silva Cabral in Portugal and to be ex- cluded from the Spanish stage, and to these two accidents it owes its survival. Le Sage likewise utilized in Gil Blas episodes taken from El Siglo pígárico (1644), the work of Antonio Enriquez Gómez (q.v.); but most of El Siglo pígárico is in verse, and as it was published at Paris by an exiled Portuguese Jew, its circulation in Spain must have been limited. The normal primitive rogue returns to the scene in La Vida y hechos de Estebanillo González (1646), which is no doubt the genuine autobiography that it purports to be. If he is still occasionally read by students he owes it to the fact that Le Sage drew upon him in the Histoire d'Estevanillo González. By the general public he is completely forgotten, and the same may be said of many subsequent Spanish writers who adopted the picaresque formula. The Buscón is the last great book of its kind.

Meanwhile, the rogue had forced his way into other European literatures. The Antwerp continuation (1558) of Lazarillo de Tormes brought the original to the notice of northern readers, and this first part was translated into French by Jean Saugrain in 1561. A Dutch version was issued anonymously in 1579, and it seems extremely likely that the book had been translated into English before this date. This follows from a manuscript note written by Gabriel Harvey in a copy of the Howelglass given him by Edmund Spenser; Harvey here mentions that he had received the Howelglass, Skoggin, Skelton and Lazarillo from Spenser on the 20th of December 1578. The earliest known edition of David Rowland's version of Lazarillo de Tormes is dated 1586, but as a licence to print a translation of this tale was granted on the 22nd of July 1588/1589, it is probable that a 1576 edition which appears in the Harleian Catalogue really existed. Numerous reprints (1599, 1659, 1669-1679, 1672, 1677) go to prove that Lazarillo de Tormes was very popular, and that Shakespeare had read it seems to follow from an allusion in Much Ado about Nothing (Act. 11, sc. i.): "Now you strike like the blind man; 't was the boy that stole your meat, and you will beat the post." To Thomas Nash belongs the credit, such as it is, of being the first to write a picaresque novel in English: The Unfortunate Traveller or the Life of Jack Wilton (1594). Nash carefully points out that his work is a new experiment, "being a cleane different veine from other my former courses of writing"; the only possible Spanish model that he can have had was Lazarillo de Tormes, but he has nothing of his predecessor's sardonic brevity, and he anticipates later Spanish writers by his emphatic insistence on the pleasures of eating and drinking to repletion. Nash led the way, and a reference to "Spanish pickaroes" in Middleton's Spanish Gipsie indicates that the picacon type had speedily become familiar enough for London players to understand the reference. Interest in picaresque literature was kept alive in England by a translation (1622) of a sequel to Lazarillo de Tormes published at Paris two years earlier by Juan de Luna, who came to London to supervise the English rendering; by James Mabbe's admirable version (1622) of Guzmán de Alfarache; by The Son of the Rogue or the Politic Thief (1638), an anonymous translation, done through the French, of La desordenada codicia; and by another anonymous translation (1657), likewise done through the French, of Quevedo's Buscón. The result of this campaign was The English Rogue described in the Life of Merion Latroon, a witty Extravagant (1653), by Richard Head and Francis Kirkman. The authors of this farrago insist on the English nationality of their chief character, and repudiate the idea that they are in any way indebted to Alemán and Quevedo. It is no exaggeration, however, to say that almost all the material in the text is taken from Spanish sources, and even the thieves' vocabulary is stolen from John Awdlesey's Fraternitie of Vacabondes or Thomas Harman's Caveat, or Warning for Common Cursetors. It is not till Defoe's time that the English picaresque novel acquires any real importance, and the picaresque intention informs much of his work that contravenes the accepted rules of composition. There is a female picacon in Moll Flanders, and, as Defoe read Spanish, it is conceivable that Moll Flanders was suggested by the Picara Justina; but this resemblance does not make a picaresque novel of Moll Flanders. The satirical spirit which is lacking in Moll Flanders in 1639; but Lazarillo and Guzmán have the desire to show the "vice and all kinds of wickedness attended with misery." Henceforward the picacon is naturalized in English literature, and is gloriously reincarnated in Fielding's Jonathan Wild and in Smollett's Ferdinand, Count Fathom. The classification of Sterne's Tristram Shandy and Morier's Hajji Baba as picaresque novels is not strictly accurate; like Pickwick and Oliver Twist and Barry Lyndon, they are rather varieties of the pereiapatetic novel, but many incidents in all five recall the pleasing wiles of the Spanish picaconos.

The Dutch translation of Lazarillo de Tormes (1579) did not enable the picaresque novel to strike root in Holland, yet from it is derived one of the best Dutch comedies, De Spaansche Brabander Joradim (1616) of Gerbrand Bredero. A German translation of Guzmán de Alfarache was published by Aegidius Alberius in 1615; both Lazarillo and Rico y Tomé y Cortadillo were translated by Niclas Ulenhart in 1617. Thomas de Thriehm in 1627 there appeared an anonymous version of the Picara Justina. The Spanish tradition was followed by Martin Frewden in a continuation (1636) of Guzmán de Alfarache, but the only original picaresque novel of real value in German is Grimmelhausen's Simplicissimus. The attempt to acclimatize the picaresque novel in Italy failed completely. Barezzo Barezi translated Guzmán de Alfarache, Lazarillo de Tormes and the Picara Justina in 1606, 1622 and 1624 respectively, and Giovanni Pietro Franco did the Buscón into Italian in 1634; but there was no important native
PICAYUNE—PICCINNI

PICAYUNE, the name in Florida and Louisiana of the Spanish half-real, = 1/4 of a dollar, 6½ cents, and hence used of the United States 5 cents, was translated into French as Picardon, from which the word was adapted in America, was a copper coin of Piedmont. Its origin is doubtful, but is possibly related to the Italian piccolo, little, small. In America the word is used of anything trifling, petty, mean or contemptible.

PICCININNY, or PICKININNY, a word applied originally by the negroes of the West Indies to their babies. It is adapted either from Span. pequeño, small, or Port. pequenino, very small. The word spread with the slave trade to America, and has since been adopted in Australia and in South Africa.

PICCININO, NICCOLÒ (1386–1444), Italian condottiere, born at Perugia, was the son of a butcher. He began his military career in the service of Braccio da Montone, who at that time was waging war against Perugia on his own account, and at the death of his chief, shortly followed by that of the latter's son Oddo, Piccinino became leader of Braccio's condotta. After serving for a short period under the Florentine Republic, he went over to Filippo Maria Visconti, duke of Milan (1425), in whose service together with Niccolò Fortebraccio he fought in the wars against the league of Pavia, Eugene TV., Venice and Florence. He defeated the papal forces at Cast Belegnaese (1434), but another papal army under Francesco Sforza having defeated and killed Fortebraccio at Fieridmonte, Piccinino was left in command, and in a series of campaigns against Sforza he seized a number of cities in Romagna by treachery. In 1439 he again fought in Lombardy with varying success against Sforza, who had now entered the Venetian service. Piccinino then induced the duke of Milan to send him to Umbria, where he hoped, like so many other condottieri, to carve out a dominion for himself. He was defeated by Sforza at Anghari (1440), but although a number of his men were taken prisoners they were at once released, as was usually done in wars waged by soldiers of fortune. Again the war shifted to Lombardy, and Piccinino, having defeated and surrounded Sforza at Martinengo, demanded of the visconti the lordship of Piacenza as the price of Sforza's capture. The duke by way of reply concluded a truce with Sforza; but the latter, who, while professing to defend the Papal States, had established his own power in the Marche, aroused the fears of the pope and the king of Naples, as well as of the visconti, who gave the command of their joint forces to Piccinino. Sforza was driven from the Marche, but defeated Piccinino at Montelaur, and while the latter was preparing for a desperate effort against Sforza he was suddenly recalled to Milan, his army was beaten in his absence, and he died of grief and of his wounds in 1444. Short of stature, lame and in weak health, he was brave to the point of foolhardiness, wonderfully resourceful, and never overwhelmed by defeat. He was cruel and treacherous, and had no aim beyond his own aggrandizement. Piccinino left two sons, Jacopo and Francesco, both distinguished condottieri.

A good account of Piccinino is contained in vol. iii. of E. Ricotti's Storia della compagnie di ventura (Turin, 1845); G. B. Poggio, Vita di G. Piccinino (Venice, 1572); see also the general histories of the period.

PICCINNI, NICCOLO (1728–1800), Italian musical composer, was born at Bari on the 10th of January 1728. He was educated under Leo and Duranté, at the Conservatorio di Sant' Onofrio in Naples. For this Piccinni had to thank the intervention of the bishop of Bari, his father, although himself a musician, being opposed to his son's following a musical career. His first opera, Le Donne dispotiche, was produced in 1755, and in 1760 he composed, at Rome, the chef d'œuvre of his early life, La Cecchina, ossia la buone
PIECOLO—PICCOLOMINI, O.

Figuola, an opera buffa which attained a European success. Six years after this Piccini was invited by Queen Marie Antoinette to Paris. He embellished in 1776 his pupil Vincenza Sibilla, a singer, whom he never allowed after her marriage to appear on the stage. All his next works were successful; but, unhappily, the directors of the Grand Opéra conceived the mad idea of deliberately opposing him to Gluck, by persuading the two composers to treat the same subject—Iphigénie en Tauride—simultaneously. The Parisian public now divided itself into two rival parties, which, under the names of Gluckists and Piccinnists, carried on an unworthy and disgraceful war. Gluck's masterly Iphigénie was first produced on the 18th of May 1779. Piccini's Iphigénie followed on the 23rd of January 1781, and, though performed seventeen times, was afterwards consigned to oblivion. The fury of the rival parties continued unabated, even after Gluck's departure from Paris in 1780; and an attempt was afterwards made to inaugurate a new rivalry with Sacchini. Still, Piccini held a good position, and on the death of Gluck, in 1787, proposed that a public monument should be erected to his memory—a suggestion which the Gluckists themselves declined to support. In 1784 Piccini was professor at the Royal School of Music, one of the institutions from which the Conservatoire was formed in 1794. On the breaking out of the Revolution in 1789 Piccini returned to Naples, where he was at first well received by King Ferdinand IV.; but the marriage of his daughter to a French democrat brought him into irretrievable disgrace. For nine years after this he maintained a precarious existence in Venice, Naples and Rome; but he returned in 1798 to Paris, where the fickle public received him with enthusiasm, but left him to starve. He died at Passy, near Paris, on the 7th of May 1800. After his death a memorial tablet was set up in the house in which he was born at Bari.

The most complete list of his works is that given in the Rivista musicale italiana, vols. xxvi. and xxvii. He produced over eighty operas, but it is believed that his later work shows the influence of the French and German stage, he belongs to the conventional Italian school of the 18th century.

See also P. L. Guguené, Notice sur la vie et les ouvrages de Niccolò Piccinni (Paris, 1801); E. Demeoiterres, La Musique française au 18e siècle Gluck et Piccinni 1774-1800 (Paris, 1872).

PICCOLO (Fr. petite flûte octave; Ger. Pickelflöte; Ital. flauto piccolo or otsatino), a small flute of less than half the dimensions of the large concert flute and pitched an octave higher. The principles of construction and the acoustic properties are the same for the piccolo as for the flute, with the exception that the piccolo does not contain the additional tail-piece with the extra low keys, which give the flute its extended compass. As the pitch of the piccolo is so high, the highest of all orchestral instruments with the exception of a few harmonics on the violin, the music for it is written an octave lower than the real sounds in order to avoid theledger lines. The piccolo has been used with good effect in imitating the whistling of the wind in storms, as in Beethoven's Pastoral Symphony, Wagner's Flying Dutchman, and in conjunction with the violins in tremolo to depict the rustling of the leaves in the breeze, as in the "Waldwaben" in Siegfried. Verdi employed it to advantage in Falstaff as a comic agent in humorous situations. The piccolo is generally in D, sometimes in E♭ or F. (K. S.)

PICCOLOMINI, the name of an Italian noble family, which was prominent in Siena (q.v.) from the beginning of the 13th century onwards. In 1220 Enghelbert d'Ogo Piccolomini received the fief of Montinari in Val d' Orcia from the emperor Frederick II. as a reward for services rendered. The family acquired houses and towers in Siena and castles in the republic's territory, including Montone and Castiglione; the last they sold to the commune in 1527. They obtained great wealth through trade and, and established court houses in Genoa, Venice, Aquileia, Trieste, and in various cities of France and Germany. Supporters of the Guelph cause in the civil broils by which Siena was torn, they were driven from the city in the time of Manfred and their houses demolished; they returned in triumph after the Angevin victories, were expelled once more during the brief reign of Conradin, and again returned to Siena with the help of Charles of Anjou. But through their riotous political activity the Piccolomini lost their commercial influence, which passed into the hands of the Florentines, although they retained their palaces, castles and about twenty fiefs, some of which were in the territory of Amalfi and of great extent. Many members of the house were distinguished ecclesiastics, generals and statesmen in Siena and elsewhere; two of them were popes, viz. Aeneas Silvius Piccolomini (Pius II., q.v.) and Francesco Piccolomini (Pius III., q.v.).

See Richter, Die Piccolomini (Berlin, 1874); A. Lisini and A. Liberati, Albero della famiglia Piccolomini (Siena, 1899); and articles by A. Lisini in the Miscellanea storica senese, 3rd series, 12, and 6th series, 17, 21, 22.

PICCOLOMINI, OCTAVIO, PRINCE (1569-1626), duke of Amalfi, Austrian general, was born on the 11th of November 1599 in Florence, and carried a piket in the Spanish service at the age of sixteen. Two years later, on the outbreak of the Thirty Years' War in Bohemia, he was appointed a captain in a cavalry regiment sent by the grand duke of Tuscany to the emperor's army, and he fought with some distinction under Bucquoi at the Uescher Berg and in Hungary. In 1624 he served for a short time in the Spanish army and then as lieutenant-colonel of Pappenheim's cuirassier regiment in the war in the Milanes. In 1627 he re-entered the Imperial service as colonel and captain of the lifeguard of Wallenstein, duke of Friedland. In this capacity he soon fell into disgrace for practising extortion at Stargard in Pomerania, but his adroitness secured him, after no long interval, the rank of "colonel of horse and foot." About this time the appointment of his younger brother to the archbishopric of Siena secured him a position of influence in the diplomatic world. Diplomatic talent was indeed almost the birthright of a member of an Italian family, that had seen two of its members occupying the papal chair, and Wallenstein freely made use of his subordinate's capacity for negotiation and intrigue. In the events of the Mantuan War Piccolomini took a prominent part in the dual rôle of the subtle diplomatist and the plundering soldier of fortune. At this moment came the invasion of Germany by Gustavus Adolphus. Piccolomini was interned at Ferrara as a hostage for the ratification of a treaty, but he added his voice to the general call for Wallenstein's reappointment as commander-in-chief. He was not, however, included in the list of promotions that followed the duke's reappearance, and he served under General Holck, an officer brought in from the Danish service, in the preliminary operations and in the battle of Lützen. His ambition was gratified when, on reading the official report of the battle, the emperor made him a general-field marshal. At the same time, however, Holck was created a field marshal at Wallenstein's instance, much to his rival's chagrin. In the campaign of 1633 Piccolomini held the command of an important detachment posted at Königgrätz to bar the enemy's advance from Silesia into Bohemia. History repeated itself on the same ground in 1756, 1778 and 1866; in the first of these cases it was a Piccolomini, grand-nephew of Octavio, who commanded the Austrians; in the last the victorious Prussians passed over the estate of Nachod, which after 1635 was a hereditary possession of the family. In May Wallenstein entered Silesia with the main army with the unavowed object of compelling or persuading the electors of Brandenburg and Saxony to make common cause with the emperor against the Swedes. Piccolomini was with him, and, disapproving of the duke's policy, joined in a military conspiracy, out of which grew the drama that ended with the murder of Wallenstein on the 25th February 1634. Piccolomini's main part in the tragedy has been set forth for all time in the pages of Schiller's Wallenstein. His reward was his marshal's baton, 100,000 gulden and the beautiful estate of Nachod in the Riesengebirge.

He was Wallenstein's pupil as well as his sayer, and had learned the art of war from that master. On the 5th–6th of September in the same year he distinguished himself amongst the foremost in the great victory of Nördlingen. He soon saw the necessity for following out the lines of military policy laid
down by the duke, but neither he nor Gallas, the new lieutenant-general of the emperor, possessed the capacity for carrying it out, and the war dragged on year after year. Piccolomini was in 1635 allied with a Spanish army, and bitterly complained that their sloth and caution marred every scheme that he formed. In 1638 he was made a count of the empire, and in 1639, having been fortunate enough to win a great victory over the French (relief of Thionville, July 7, 1639), he was rewarded with the office of privy councillor from the emperor and with the dukedom of Amalfi from the king of Spain. But instead of being appointed, as he hoped, Gallas's successor, he was called in to act as ad latus to the Archduke Leopold Wilhelm, with whom he was defeated in the second battle of Breitenfeld in 1642. After this he spent some years in the Spanish service and received as his reward the title of grandee and the order of the Golden Fleece. Some years later, having re-entered the Imperial army, he was again disappointed of the chief command by the selection of the brave veteran Peter Melander, Count Holzapfel. But when in 1648 Melander fell in battle at Zusmarshausen, Piccolomini was at last appointed lieutenant-general of the emperor, and thus conducted as generalissimo the final campaign of the weary and desultory Thirty Years' War. Three days after the commission for executing the peace had finished its labours, the emperor addressed a letter of thanks to "the Prince Piccolomini," and awarded him a gift of 114,566 gulden. Piccolomini died on the 11th of August 1656. He left no children (his only son Joseph Silvio, the "Max" of Schiller's Wallenstein, was murdered by the Swedes after the battle of Jankau in 1654), and his titles and estates passed to his brother's son. With the death of the latter's nephew Octavio Aeneas Joseph in 1757, the line became extinct.

**PICENE**, C₂₂H₄₆, a hydrocarbon found in the pitchy residue obtained in the distillation of peat-tar and of petroleum. This is distilled to dryness and the distillate repeatedly recrystallized from cyrene. It may be synthetically prepared by the action of anhydrous aluminium chloride on a mixture of naphthenate and ethylene dibromide (R. Lespieau, Bull. soc. chim., 1891, (3), p. 238), or by distilling a-dinaphthostilbene (T. Hira, Ber., 1890, 32, p. 3341). It crystallizes in large colourless plates which possess a blue fluorescence. It is soluble in concentrated sulphuric acid with a green colour. Chrocin acid in glacial acetic acid solution oxidizes it to picene-quinone, picene-quinone carboxylic acid, and finally to phthalic acid. When heated with hydriodic acid and phosphorus it forms hydrides of composition C₂₂H₄₆ and C₂₂H₃₄ (see E. Bamberger and F. D. Chattaway, Ann., 1895, 284, p. 61).

**PICENUM**, a district of ancient Italy, situated between the Apennines and the Adriatic, bounded N. by the Senones and S. by the Vescani. The inhabitants were, according to tradition, an offshoot of the Sabines. Strabo (v. 4, 1) gives the story of their migration, led by a woodpecker (picus), a bird sacred to Mars, from which they derived their name Ficentini (cf. Dion. Hal. i. 14, 7), just as the Hirpinii derived theirs from hierpus, a wolf. The district was conquered by the Romans early in the 3rd century B.C. and the whole territory was divided up among Latin-speaking settlers by the Lex Flaminia in 232 B.C. Hence we have very scanty records of any non-Latin Language that may have been spoken in the district before the 3rd century. Besides the problematic inscriptions from Belmonte, Nereto and Cupra Maritima (see Sabellio), we have one or two Latin inscriptions (probably of the 2nd or even of the 1st century B.C.) which contain certain forms showing a distinct affinity with the dialect of Iguvium (cf. the name Palli-Lat. Pacidi). Hence there seems no ground for believing that the population which the Romans dispossessed, or held in subjection, really spoke a dialect very much like that of their neighbours in Umbria.

For inscriptions, see R. S. Conway, The Italic Dialects, p. 449, where the place-names and personal names of the district will also be found; see further, Livy, Epit. xv.; B. V. Head, Historia Romanorum, p. 19. (R. S. C.)

It was in Picenum, at Asculum, that the Social War broke out in 90 B.C. At the end of the war the district became connected with Pompeius Strabo, and his son Pompey the Great threw into the scale on the side of Sulla, in 83 B.C., all the influence he possessed there, and hoped to make it a base against Caesar's legions in 49 B.C. Under Augustus it formed the fifth region of Italy, and included twenty-three independent communities, of which five, Ancona, Firmum, Asculum, Hadria and Interamnia, were coloniae. It was reached from Rome by the Via Salaria, and its branch the Via Caecilia. It was also on a branch leading from the Via Flaminia at Nuceria Camallaria to Septempeda. There were also communications from north to south; a road led from Asculum to Urbis Salvia and Ancona, another from Asculum and Firmum and the coast, another from Urbis Salvia to Potentia, while finally along the whole line of the coast there ran a prolongation of the Via Flaminia, the name of which is not known to us.

At the end of the 2nd century A.D. the north-eastern portion of Umbria was divided from the rest and acquired the name Flaminia, from the high road. For the time it remained united with Umbria for administrative purposes, but passed to Picenum at latest in the time of Constantine, and acquired the name of Flaminia et Picenum Annorumium, the main portion of Picenum being distinguished as Suburbicarium. In an inscription of A.D. 399 Ravenna is actually spoken of as the chief town of Picenum.

When the exarchate of Ravenna was founded the part of Picenum Annorumium near the sea became the Pentapolis Maritima, which included the five cities of Ariminum, Pisauro, Fanum Fortunae, Sena Gallica and Ancona. The exarchate was seized by Luitprand in 727, and Ravenna itself was taken by Aistulf in 752. In the next year, however, the Emperor Pippin took it from him and handed it over to the pope, a grant confirmed by his son Charlemagne. (T. As.)

**PICHGRU, CHARLES** (1761-1804), French general, was born at Arbois, or, according to Charles Nordier, at Les Planches, near Lons-le-Saulnier, on the 16th of February 1761. His father was a labourer, but the friars of Arbois gave the boy a good education, and one of his masters, the Père Partault, took him to the military school of Brienne. In 1783 he entered the first regiment of artillery, where he rapidly rose to the rank of adjutant-sub-lieutenant. When the Revolution began he became leader of the Jacobin party in Besançon, and when a regiment of volunteers of the department of the Gard marched through the city he was elected lieutenant-colonel. The fine condition of his regiment was soon remarked in the army of the Rhine, and his organizing ability was made use of by an appointment on the staff, and finally by his promotion to the rank of general of brigade. In 1793 Carnot and Saint Just were sent to find roturier generals who could be successful; Carnot discovered Jourdan, and Saint Just discovered Pichgru. This regiment, now in the service of the exarch of Lombez and the army of the Moselle, Pichgru, now general of division and in command of the army of the Rhine, had to reconquer Alsace and to reorganize the disheartened troops of the republic. They succeeded; Pichgru made use of the élan of his soldiers to win innumerable small engagements, and with Hoche forced the lines of Haguenau and relieved Landau. In December 1793 Hoche was arrested, it is said owing in part to his colleague's machinations, and Pichgru became commander-in-chief of the army of the Rhine-and-Moselle, whence he was summoned to succeed Jourdan in the army of the North in February 1794. It was now that he fought his three great campaigns of one year. The English and Austrians held a strong position along the Sambre to the sea. After vainly attempting to break the Austrian centre, Pichgru suddenly turned their left, and defeated Clerfayt at Cassel, Meeuwen and Courtrai. Thereafter, under Pichgru in command, defeated Coburg at Tourcoing in May 1794; then after a pause, during which Pichgru feigned to besiege Ypres, he again dashed at Clerfayt and defeated him at Rousselare and Hooglede, while Jourdan came up with the new army of the Sambre-and-Meuse, and utterly routed the Austrians at Fleurus on the 27th of June 1794. Pichgru began his second campaign by crossing the Meuse on the 18th of October, and after taking Nijmegen drove the Austrians beyond the Rhine. Then, instead of going into winter-quarters, he prepared for a winter campaign by assembling his army at Tournai.
campaign. On the 28th of December he crossed the Meuse on the ice, and stormed the island of Bommel, then crossed the Waal in the same manner, and, driving the English before him, entered Utrecht on the 10th of January, and Amsterdam on the 20th of January, and soon occupied the whole of Holland. This great feat of arms was marked by many points of interest, such as the capture of the Dutch ships, which were frozen in the Helder, by the French hussars, and the splendid discipline of the ragged battalions in Amsterdam, who, with the richest city of the continent to sack, yet behaved with a self-restraint which few revolutionary and Napoleonic armies attained. The former friend of Saint Just now offered his services to the Thermidorians, and after receiving from the Convention the title of "Sauveur de la Patrie," subdued the sans-culottes of Paris, when they rose in insurrection against the Convention on 12 Germinal (April 1). Pichegru then took command of the armies of the North, the Sambre-and-Meuse, and the Rhine, and crossing the Rhine in force took Mannheim in May 1795. When his fame was at its height he allowed his colleague Jourdan to be beaten, betrayed all his plans to the enemy, and took part in organizing a conspiracy for the return of Louis XVIII., in which he was to play, for his own aggrandizement, the part that Monk played from higher motives in the English revolution. His intrigues were suspected, and when he offered his resignation to the Directory in October 1795 it was to his surprise promptly accepted. He retired in disgrace, but hoped to serve the royalist cause by securing his election to the Council of Five Hundred in May 1797. He was there the royalist leader, and planned a coup d'état, but on the 18th Fructidor he was arrested, and with fourteen others deported to Cayenne in 1797. Escaping, he reached London in 1798, and served on General Korsakov's staff in the campaign of 1799. He went to Paris in August 1803 with Georges Cadoudal to head a royalist rising against Napoleon; but, betrayed by a friend, he was arrested on the 28th of February, 1804, and on the 15th of April was found strangled in prison. It has often been asserted that he was murdered by the orders of Napoleon, but there is no foundation for the story.

Pichegru's campaigns of 1794 are marked by traits of an audacious genius which would not have disgraced Napoleon. His tremendous physical strength, the personal ascendency he gained by this and by his powers of command made him a peculiarly formidable opponent, and thus enabled him to maintain a discipline which guaranteed the punctual execution of his orders. He had also, strangely enough, the power of captivating honest men like Moreau. He flattered in turn Saint Just and the Terrorists, the Thermidorians and the Directors, and played always for his own hand—a strange egotist who rose to fame as the leader of an idealist and sentimental crusade.

There is no really good life of Pichegru; perhaps the best is J. M. Guizot's Vie du général Pichegru (Paris, 1835). For his trousseau, the depository of his Memoirs, there is la trahison de Pichegru (1804); Fauche-Borel's Mémoires; Savary's Mémoires sur la mort de Pichegru (Paris, 1825); and G. Pierret, Pichegru, son procès et sa mort (1826).

**PICHLER, CAROLINE** (1769-1843). Austrian novelist, was born at Vienna on the 7th of September 1769, the daughter of Hofrat Franz von Greiner, and married, in 1796, Andreas Pichler, a government official. For many years her salon was the centre of the literary life in the Austrian capital, where she died on the 9th of July 1843. Her early works, Olivier, first published anonymously (1802), Idylle (1803) and Ruth (1805), though displaying considerable talent, were immatures. She made her mark in historical romance, and the first of her novels of this class, Aurora (1806), was chosen by Madame du Barry's attack on her hero in the Decline and Fall of the Roman Empire added great popularity. Among her other novels may be mentioned Die Belagerung Wiens (1824); Die Schweden in Prag (1827); Die Wiedererobung Offens (1899) and Henriette von England (1832). Her last work was Zeitbilder (1846).

The edition of Caroline Pichler's Sämtliche Werke (1820-1845) comprises no less than 60 volumes. Her Denkwürdigkeiten aus meinem Leben (4 vols.) was published posthumously in 1844. A selection of her narratives, Ausgewählte Erzählungen, appeared in 4 vols. in 1894.

**PICKENS, ANDREW** (1739-1817). American soldier in the War of Independence, was born in Paxton, Bucks county, Pennsylvania, on the 19th of September 1739. His family settled at the Waxhaws (in what is now Lancaster county), South Carolina, in 1752. He fought against the Cherokees in 1761 as a lieutenant. In the War of Independence he rose to brigadier-general (after Cowpens) in the South Carolina militia. He was a captain among the American troops which surrendered at Ninety Six in November 1775. On the 14th of February 1779, with 300-400 men, he surprised and defeated about 700 Loyalists under Colonel Boyd on Kettle Creek, Wilkes county, Georgia; on the 20th of June he fought at Stono Ferry; and later in the same year at Tomasse defeated the Cherokees, who were allied with the British. Upon the surrender of Charleston (May 1780) he became a prisoner on parole, which he observed readily, in contrast to the promises made to him, Major James Dunlap plundered his plantation; he then returned to active service. His command (about 150 men) joined General Daniel Morgan immediately before the battle of Cowpens, in which Pickens commanded an advance guard (270-350 men from Georgia and North Carolina) and twice rallied the broken American militia; for his services Congress gave him a sword. With Colonel Henry Lee he harassed Lieut.-Colonel Banastre Tarleton, who was attempting to gather a Loyalist force just before the battle of Guilford Court House; and with Lee and others, he captured Augusta (June 5, 1781) after a siege. At Eutaw Springs (Sept. 8, 1781) he commanded the left wing and was wounded. In 1782 he defeated the Cherokees again and forced them to surrender all lands south of the Savannah and east of the Chattoohoochee. After the war he was a member of the South Carolina House of Representatives for a number of years, of the state Constitutional Convention in 1779, and of the National House of Representatives in 1793-1797. He died in Pendleton district, South Carolina, on the 17th of August 1817. He had married in 1765 Rebecca Calhoun, an aunt of John C. Calhoun. Their son, Andrew Pickens (1779-1838), served as a lieutenant-colonel in the War of 1812, and was governor of South Carolina in 1816-1818.

**PICKENS, FRANCIS WILKINSON** (1805-1869), American politician, was born in Togadoo, St Paul's parish, South Carolina, on the 7th of April 1805, son of Andrew Pickens (1779-1838) and grandson of General Andrew Pickens (1759-1817). He was educated at Franklin College, Athens, Georgia, and at South Carolina College, Columbia, and was admitted to the bar in 1829. In 1832 he was elected to the state House of Representatives, where, as chairman of a sub-committee, he submitted a report denying the right of Congress to exercise any control over the states. He was a Democratic member of the National House of Representatives in 1834-1843, served in the South Carolina Senate in 1844-1845, was a delegate to the Nashville Southern Convention (see NASHVILLE, TENNESSEE) in 1850, was United States minister to Russia in 1858-1860, and in 1866-1862 was governor of South Carolina. He strongly advocated the secession of the Southern states; signed the South Carolina ordinance of secession; protested against Major Robert Anderson's removal from Fort Moultrie to Fort Sumter; sanctioned the firing upon the "Star of the West" (Jan. 9, 1861), which was bringing supplies to Anderson, and the bombardment of Fort Sumter; and was a zealous supporter of the Confederate cause. At the close of his term he retired to his home at Edgefield, South Carolina, where he died on the 25th of January 1877.

**PICKERING, EDWARD CHARLES** (1845- ). American physiologist and astronomer, was born in Boston on the 10th of July 1846. He graduated in 1865 at the Lawrence Scientific School of Harvard, where for the next two years he was a teacher of mathematics. Subsequently he became professor of physics at the Massachusetts Institute of Technology, and in 1876 he was appointed professor of astronomy and director of the Harvard College observatory. In 1877 he decided to
devote one of the telescopes of the observatory to stellar photometry, and after an exhaustive trial of various forms of photometers, he devised the meridian photometer (see Photometry, Stellar), which seemed to be free from most of the sources of error. With the first instrument of this kind, having objectives of 1.5 inch aperture, he measured the brightness of 4260 stars, including all stars down to the 6th magnitude between the North Pole and -30° declination. With the object of reaching fainter stars, Professor Pickering constructed another instrument of larger dimensions, and with this more than a million observations have been made. The first important work undertaken with it was a revision of the magnitudes given in the Bonn Durchmusterung. On the completion of this, Professor Pickering decided to undertake the survey of the southern hemisphere. An expedition, under the direction of Prof. S. I. Bailey, was accordingly despatched (1880), and the meridian photometer erected successively in three different positions on the slopes of the Andes. The third of these was Arequipa, at which a permanent branch of the Harvard Observatory is now located. The magnitudes of nearly 8000 southern stars were determined, including 1428 stars of the 6th magnitude and brighter. The instrument was then returned to Cambridge (U.S.A.), where the survey extended so as to include all stars of magnitude 7.5 down to 40° declination after the 25th of March. The total number of stars measured was 12,000, of which 6000 were considered definite. He in 1886 the widow of Henry Draper, one of the pioneers of stellar spectroscopy, made a liberal provision for carrying on spectroscopic investigations at Harvard College in memory of her husband. With Professor Pickering's usual comprehensiveness, the inquiry was so arranged as to cover the whole sky; and with four telescopes—two at Cambridge for the northern hemisphere, and two at Arequipa in Peru for the southern—towards which a fine 24-inch photographic telescope was afterwards added, no fewer than 75,000 photographs had been obtained up to the beginning of 1901. These investigations have yielded many important discoveries, not only of new stars, and of large numbers of variable stars, but also of a wholly new class of double stars whose binary character is only revealed by peculiarities in their spectra. The important conclusion has been already derived that the majority of the stars in the Milky Way belong to one special type.

PICKERING, TIMOTHY (1745-1829), American politician, was born at Salem, Massachusetts, on the 17th of July 1745. He graduated from Harvard College in 1763 and was admitted to the bar in 1773. In 1776 he became a member of the Massachusetts Provincial Congress, where he identified himself with the American Whigs; in 1773 he prepared for Salem a paper entitled State of the Rights of the Colonists; in 1775 he drafted a memorial protesting against the Boston Port Bill; and in 1776 he was a representative from Salem in the General Court of Massachusetts. In 1769 he had been commissioned lieutenant and in 1790 captain in the Essex county militia; early in 1775 he published An Easy Plan of Discipline for a Militia, adopted in May 1776 by the General Court for use by the militia of Massachusetts, and he was elected colonel of his regiment. In the same year he became judge of the court of common pleas for Essex county, and sole judge of the maritime court for the counties of Suffolk, Essex and Middlesex. In the winter of 1776-1777 he led an Essex regiment of volunteers to New York, and he subsequently served as adjutant-general (June 1777-Jan. 1778) and later as quartermaster-general (1780-1783); he was also a member of the board of war from the 7th of November 1777 until its abolition. With the aid of some officers he drew up, in April 1783, a plan for the settlement of the North-West territory, which provided for the exclusion of slavery. In 1785 he became a commissioner at Philadelphia: but in October 1786, soon after the legislature of Pennsylvania had passed a bill for erecting Wyoming district into the county of Luzerne, he was appointed prothonotary and a judge of the court of common pleas and clerk of the court of sessions and orphans' court for the new county, and was commissioned to organize the county. He offered to purchase for himself the Connecticut title to a farm, and in the following year he was appointed a member of a commission to settle claims according to the terms of an act, of which he was the author, confirming the Connecticut titles (see Wyoming Valley and Wilkes-Barre). Pickering was a member of the Pennsylvania convention of 1777 which ratified the Federal constitution, and of the Pennsylvania constitutional convention of 1786-1790. In November 1790 he negotiated a peace with the Seneca Indians, and he concluded treaties with the Six Nations in July 1791, in March 1792 and in November 1794. Under Washington he was postmaster-general (1791-1795), secretary of war (1795), and after December 1795 secretary of state, to which position he was reappointed (1797) by Adams. In 1783, while he was quartermaster-general, he had presented a plan for a military academy at West Point, and now, as secretary of war, he supervised the West Point military post with a view to its conversion into a military academy. As head of the state department he soon came into conflict with Adams. His hatred of France made it impossible for him to sympathize with the president's efforts to settle the differences with that country on a peaceable basis. He used all his influence to harass the president and to advance the political interests of Alexander Hamilton, until he was dismissed, after refusing to resign, in May 1800. Returning to Massachusetts, he served as chief justice of the court of common pleas of Essex county in 1802-1803. He was a member of the United States Senate from Massachusetts, and was a member of the Federal House of Representatives in 1813-1817. As an ultra Federalist—he was a prominent member of the group known as the Essex Junto—he strongly opposed the purchase of Louisiana and the War of 1812. He died at Salem, Massachusetts, on the 29th of January 1829.

The standard biography is that by his son, Octavius Pickering (1791-1868), and C. W. Upham, The Life of Timothy Pickering (Boston, 1867-1875). In the library of the Massachusetts Historical Society at Boston, there are sixty-two manuscript volumes of the Pickering papers, an index to which is published in the Collections of the society, 6th series, vol. viii. (Boston, 1896).

His son, JOHN PICKERING (1777-1846), graduated at Harvard in 1796, studied law and was private secretary to William Smith, United States minister to Portugal, in 1797-1799, and to Rufus King, minister to Great Britain, in 1799-1801. He practised law in Salem and (after 1827) in Boston, where he was city solicitor in 1827-1846, and wrote much on law and especially on the languages of the North-American Indians. He was a founder of the American Oriental Society and published an excellent Comprehensive Dictionary of the Greek Language (1819).

See Mary O. Pickering (his daughter), Life of John Pickering (Boston, 1887).

Timothy Pickering's grandson, CHARLES PICKERING (1805-1878), graduated at Harvard College in 1823 and at the Harvard Medical School in 1826, practised medicine in Philadelphia, was naturalist to the Wilkes exploring expedition of 1838-1842, and in 1843-1845 travelled in East Africa and India. He wrote The Races of Man and their Geographical Distribution (1848), Geographical Distribution of Animals and Man (1854), Geographical Distribution of Plants (1861) and Chronological History of Plants (1879).

PICKERING, a market town in the Whitby parliamentary division of the North Riding of Yorkshire, England, 32 m. N.E. by N. from York by the North Eastern railway, the junction of several branch lines. Pop. of urban district (1901), 3491. The church of St Peter is Norman and transitional Norman, with later additions including a Decorated spire. It contains a remarkable series of mural paintings of the 15th century. The castle, on a hill to the north, is a picturesque ruin, Date of construction 1183-1237 towers remaining. The church contains stained glass from 1300. The work is in part Norman, but the principal portions are of the 14th century. One of the towers is connected in name and story with Fair Rosamond. The castle was held by Earl Morcar shortly before the Conquest; it then came into the hands of the Crown, and subsequently passed to the duchy of Lancaster. It was the prison of Richard II. before his confinement at Pontefract. During the civil wars of the 17th century the castle was held by the Royalists, and suffered greatly in siege. The district
surrounding Pickering is agricultural, and the town is a centre of the trade. Agricultural implements are manufactured, and lime and stone and freestone are quarried in the vicinity.

**PICKET, PIQUE or PIQUET (Fr. *pique*, a pointed stake or peg, from *piquer*, to point or pierce), a military term, signifying an outpost or guard, supposed to have originated in the French army about 1600, from the circumstance that an infantry company on outpost duty dispersed its musketeers to watch, the small group of pikemen called *pique* remaining in reserve. Thus at the present day the word "picket" is, in Great Britain at any rate, restricted to an infantry post on the outpost line, from which the sentries or "groups" of watchers are sent out. In the United States a "picket" is synonymous with a sentry, and the "picket-line" is the extreme advanced line of observation of an army. In the French army piqûres are called "grand' gardes," and the phrase "grand guard" is often met with in English military works of the 17th and 18th centuries. A body of soldiers held in readiness for military or police duties within the limits of a camp or barracks is also called a piqûre or "inlying piqûre." These special uses of the word in English are apparently obsolete modern (after about 1750). "Picket" in its ordinary meaning of a peg or stake, has always been in common military use, being applied variously to the picketing pegs in horse-lines, to long pointed stakes employed in palingades or stockades, to straight thin rods used for marking out the line of fire for guns, &c. Of the various spellings "pîque" is officially adopted in Great Britain and "picket" in the United States, but the latter is now invariably used when a peg or stake is meant.

Two obsolete meanings of the word should also be mentioned. The "picket" was a form of military punishment in vogue in the 16th and 17th centuries, which consisted in the offender being forced to stand on the narrow flat top of a peg for a period of time. The punishment died out in the 18th century and was so far unfamiliar to 1880 that Sir Thomas Picton, who ordered a mulatto woman to be so punished, was accused by public opinion in England of inflicting a torture akin to imprisonment. It was thought, in fact, that the woman was forced to stand on the head of a pointed stake, and this error is repeated in the *New English Dictionary*. In the middle of the 19th century, when elongated rifle bullets were a novelty, they were often, and especially in America, called pickets. The ordinary military use of the word gives rise to compound forms such as "picket boat" or "picket launch," large steam launch or pinnaece fitted with guns and torpedoes, and employed for watching the waters of harbours, &c. For picketing in strikes, &c., see below.

**PICKETING, a term used to describe a practice resorted to by workmen engaged in trade disputes, of placing one or more men near the works of the employer with whom the dispute is pending, with the object of drawing off his hands or acquiring information useful for the purposes of the dispute. In England, under the Conspiracy and Protection of Property Act 1875, it is an offence wrongfully and without legal authority to watch or beset the house or place where the works or factories are carried on, or the person engaged in them happens to be, or the approach to such house or place, if the object of the watching, &c., is to compel the person watched, &c., to abstain from doing or to do an act which he is legally entitled to do or to abstain from doing (§ 7). The definition of the offence was qualified by a proviso excluding from punishment those who attend at or near a house or place merely to obtain or communicate information, in other words what is termed peaceful picketing, without intimidation, molestation or direct efforts to influence the course of a trade dispute. This enactment led to a great deal of litigation between trade unions and employers; and trade unions were in some instances restrained by injunction from picketing the works of employers. The decisions of the courts upon this subject met with severe criticism from the leaders of trade unions, and by the Trades Disputes Act 1906 the proviso above quoted was repealed, and it was declared lawful for one or more persons acting for themselves or for a trade union or for an individual employer to attend at or near a house. &c., "if the attendance is merely for the purpose of peacefully obtaining or communicating information or of peacefully persuading any person to work or abstain from working." The exact effect of this change in the law has not yet been determined by the courts, but during the Belfast carriers' strike of 1907 serious riots ensued upon the efforts of the authorities to counteract the interference with lawful business caused by free use of picketing. The change in the law is supplemented by provisions forbidding actions against trade unions in respect of any tortious acts alleged to have been committed by or on behalf of the union.

**PICKLE.** In the wider sense the term "pickle" is applied to any saline or acid preservative solution; in the narrower to vegetables preserved in vinegar. The word appears to be an adaptation of Dutch *pekel*, brine, pickle; cf. Ger. *Pökél*. The ultimate origin is unknown; connexions with a supposed inventor's name, such as *Beukeler* or *Böckel*, are mere inventions. A solution of copper or zinc sulphate is used as a "pickle" for railway-sleepers or other wood, a brine containing salt and saltpetre as a preservative for meat, lime-water as "pickle" for eggs. Domestic pickles are made from small cucumbers, onions, cauliflower, cabbage, mangolds, and unripe melons, by either steeping or boiling them in salt-brine and vinegar. On account of the large proportion of water natural to these vegetables, only the strongest vinegar, containing from 5 to 6% of acetic acid, can be used. For the better kinds vinegar made from malted or unmalted barley is as a rule employed, for cheaper varieties simply dilute acetic acid obtained from acetate of lime. Sauces such as Worcestershire sauce, or Yorkshire relish, consist of fluid pickles, that is of salted and variously spiced vinegar solutions or emulsions containing tissue of vegetables (tomatoes, mushrooms, &c.), or of fish (sardines and anchovies).

**Picknell, William Lamb** (1854–1897), American landscape-painter, was born at Hinesburg, Vermont, on the 23rd of October 1854. He was a pupil of George Inness in Rome for two years, and of J. L. Gérôme in the Ecole des Beaux Arts, Paris. With Robert Wylie he worked for several years in Brittany at Pont Aven and Concarneau, where he painted his "Route de Concarneau" (Corcoran Art Gallery, Washington, D.C.). His "Morning on the Loing" received a gold medal at the Paris Salon of 1895. In 1880 he became a member of the Society of American Artists, and in 1891 an associate of the National Academy of Design. He died at Marblehead, Massachusetts, on the 8th of August 1897.

**Picnic,** a form of entertainment in which the guests are invited to join an excursion to some place where a meal can be taken in the open air. During the first half of the 19th century the essential of a picnic was that the guests should each bring with them a contribution of provisions. At the beginning of the 19th century a society was formed in London called the "Picnic Society," the members of which supped at the Pantheon in Oxford Street, and drew lots as to what part of the meal each should supply (see L. Melville, *The Beaux of the Regency*, 1908, p. 222). The French term *pique-nique* is said to be of recent origin, perhaps from *pique* (cf. *pique*), and *nique* (cf. *nique*), a small coin.

**Pico,** an island in the Atlantic Ocean, belonging to Portugal, and forming part of the Azores archipelago. Pop. (1900), 24,028; area 175 sq. m. Pico is a conical mountain, rising to the height of 7012 ft. The soil consists entirely of pulverized lava. The so-called Fayal wine, though named after an adjacent island, was formerly produced here, and largely exported to Europe. But in 1832 the vines were attacked by the *Oidium* fungus and completely destroyed, while the orange-trees suffered almost as much from the *Coccus hesperidum*. The people were consequently forced to emigrate in great numbers, till the planting of fig-trees and apricots alleviated the evil. Pico also produces a species of wood resembling mahogany, and equal in quality to it. Its chief town is Lagoa do Pico. Pop. (1917), 9,500.

**Pico della Mirandola,** Giovanni, Count (1443–1494), Italian philosopher and writer, the youngest son of Giovanni
Francesco Pico, prince of Mirandola, a small territory about 30 Italian miles west of Ferrara, afterwards absorbed in the duchy of Modena, was born on the 24th of February 1463. The family was illustrious and wealthy, and claimed descent from Constantine. In his fourteenth year Pico went to Bologna, where he studied for two years, and was much occupied with the Decretals. The traditional studies of the place, however, disgusted him; and he spent seven years wandering through all the schools of Italy and France and collecting a precious library. Besides Greek and Latin he knew Hebrew, Chaldee and Arabic; and his Hebrew teachers (Eliaah del Medigo, Leo Abarbanel and Jochnanan Aleman)—see L. Geiger Johann Reuchlin (1871), p. 167—introduced him to the Kabbalah, which had great fascinations for one who loved all mystic and theosophic speculation. His learned wanderings ended (1486) at Rome, where he set forth for public disputation a list of nine hundred questions and conclusions in all branches of philosophy and theology. He remained a year in Rome, but the disputation he possessed was never held. The pope prohibited the little book in which they were contained, and Pico had to defend the impugned theses (De omnibus re scibili) in an elaborate Apologia. His personal orthodoxy was, however, subsequently vindicated by a brief of Alexander VI., dated 18th June 1493. The suspected theses included such points as the following: that Christ descended ad inferos not in His real presence but quoad effectum; that no image or cross should receive latreia even in the sense allowed by Thomas; that it is more reasonable to regard Origen as saved than as damned; that it is not in a man's free will to believe or disbelieve an article of faith as he pleases. But perhaps the most startling thesis was that no science gives surer conviction of the divinity of Christ than "magia" (i.e., the knowledge of the secrets of the heavenly bodies) and Kabbalah. Pico was the first to seek in the Kabbalah a proof of the Christian mysteries and it was by him that Reuchlin was led into the same delusive path.

Pico had been up to this time a gay Italian nobleman; he was tall, handsome, fair-complexioned, with keen grey eyes and yellow hair, and a great favourite with women. But his troubles led him to more serious thoughts; and he published, in his 28th year, the Heptaplius, a mystical exposition of the creation. Next he planned a great seven-fold work against the enemies of the Church, of which only the section directed against astrology was completed. After leaving Rome he again lived a wandering life, often visiting Florence, to which he was drawn by his friends Politian and Marsiliius Ficinus, and where also he came under the influence of Savonarola. It was at Florence that he died on the 17th of November 1494. Three years before his death he parted with his share of the ancestral principality, and designed when certain literary plans were completed, to give away all he had and wander barefoot through the world preaching Christ. But these plans were cut short by a fever which carried him off just at the time when Charles VIII. was at Florence.

Pico's works cannot now be read with much interest, but the man himself is still interesting, partly from his influence on Reuchlin and partly from the spectacle of a truly devout mind in the brilliant circle of half-pagan scholars of the Florentine renaissance.

His works were published at Bologna in 1496 by his nephew, Giov. Frao. Pico, with a biography, which was translated by Sir Thomas More as Life of John Picas, Earl of Mirandola, in 1510. See the essay in Walter Pater's Renaissance (1878); and the study by J. Rigg, prefixed to the reprint of More's Life in the "T. C. L. Library" (London, 1890).

PICRIC ACID, or Trinitrophenol, C₆H₂·OH·(NO₂)₃ [\(2\times 2\cdot 4\cdot 6\)], an explosive and dye-stuff formed by the action of concentrated nitric acid on indigine (a base which forms bitter salts), leather, &c. It is the final product of the direct nitration of phenol, and is usually prepared by the nitration of the mixture of phenol sulphonic acids obtained by heating phenol with concentrated sulphuric acid (E. Eisenmann and A. Arche, Engl. pat., 4530 (1889)). It may also be obtained by oxidizing the symmetrical trinitrobenzene with potassium ferricyanide in alkaline solution (F. Hepp, Ann. 1882, 215, p. 352). It crystallizes from water in yellow plates melting at 128° C., which sublime on careful heating, but explode when rapidly heated. It is poisonous and possesses a bitter taste, hence its name from the Greek πικρός, bitter. It has a strongly acid reaction, being almost comparable with the carbonylic acids. By the action of bleaching powder it is converted into chlorpicric, CCl₂·NO₂. Phosphorus pentachloride converts it into picryl chloride, C₆H₅·Cl(NO₂)₂, which is a true acid chloride, being decomposed by water with the regeneration of picric acid and the formation of hydrochloric acid; with ammonia it yields picramide, C₆H₅·NH₂(NO₂)₃. Silver picrate and methyl iodide yield the methyl ester, which gives with ammonia picramide. Picric acid forms many well-defined salts, of a yellow or red-brown colour. It also yields crystalline compounds with many aromatic hydrocarbons and bases. It imparts a yellow colour to wool and silk. The chief application of picric acid is in the manufacture of explosives. When ignited, picric acid burns quietly with a smoky flame, and it is very difficult to detonate by percussion; its salts, however, are more readily detonated. The more important picric powders are melinite, believed to be a mixture of fused picric acid and gun-cotton; lydite, the British service explosive, and shimeose, the Japanese powder, both supposed to be identical with the original melinite; Brugère's powder, a mixture of 54 parts of ammonium picrate and 45 parts of saltpetre; Desingelle's powder, composed of potassium picrate, saltpetre and charcoal; and emmensite, invented by Stephen Emmens, of the United States.

It may be detected by the addition of an aqueous solution of potassium cyanide, with which it gives a violet-red coloration, due to the formation of isopurpuric acid. R. Anschutz (Ber., 1884, 17, p. 439) estimates picric acid by precipitation with acridine.

PICRITE (from Gr. πικρός, bitter, because these rocks are rich in melinite, a base which forms bitter salts), a rock belonging to the ultrabasic group, and consisting mainly of olivine and augite often with hornblende and biotite and a greater or less amount of plagioclase felspar. The picrites are of "hypabyssal" origin and in their natural occurrence are connected with dolerites (diabases and tesanites). The distinction between them and the peridotites, which have an essentially similar composition, is not easy to define, but the peridotites accompany the truly plagioclase rocks, such as gabbro, norite and pyroxenite, are often very coarsely crystalline, and form large bosses and laccolites, while the picrites usually are found in sills or intrusive sheets.

In hand specimens the picrites are dark green to black; the absence or scarcity of lath-shaped plagioclase felspars distinguishes them from diabases and they rarely have the lustre-mottling which is a characteristic of the peridotites. Since they contain much olivine they readily decompose, passing into deep green and brown incoherent masses in which are embedded rounded lumps of harder consistency. They have a high specific gravity (about 3.0) and may be distinctly magnetic, because they are rich in iron ores. Porphyritic structure is rare though occurring sometimes in the rocks known as picrite-porphyriths; the phenocrysts are olivine and augite. There is seldom any fine-grained or glassy groundmass, and the typical microstructure is holocrystalline, moderately fine grained and somewhat poikilitic. Olivine is abundant in rounded pale green crystals. It may form one half of the rock but rarely more than this. The augite is generally brown or reddish-brown, sometimes violet, and tends to enclose the olivine, yielding poecilitic aggregates. Brown hornblende often occurs as marginal growths around the pyroxene, and may be so abundant as to replace augite to a large extent; rocks of this class are known as hornblende-peridotites. Light green or pale grey hornblende are frequently present, and in many cases are really of secondary origin. Deep brown biotite is a frequent accessory mineral and both biotite and hornblende sometimes enclose olivine. A small amount of basic plagioclase occurs in many picrites; apatite, iron oxides, chromite and spinels are minor ingredients seldom altogether absent.
PICROTOXIN—

The minerals of picrites are very frequently decomposed. Serpentine partly or wholly replaces olivine, forming radiate fibrous masses; the birefringence of yellow or red in microscopic sections. Sometimes hornblende (pilite), talc, chlorite and mica appear as secondary products after olivine. The augite passes into chlorite or into green fibrous or platy amphibole. Hornblende and biotite are often fresh when the other components are much altered. The felspar is rarely in good preservation but yields epidote, prehnite, sericite, kaolin; calcite and analcite are abundant in some weathered picrites.

Rocks of this type are well represented in Great Britain. In the central valley of Scotland several masses of picrite have been discovered (Piccon, Ithaca, etc.), associated with olivine or tachschistone. One of these forms the island of Inchcolm in the Firth of Forth, another lies near Bathgate (in Linlithgowshire), and there are others at Aberdour (Fife), Arredrossen and Barnton (Midlothian). These rocks belong to the great series of Carboniferous eruptive rocks of the Scottish midland valley. These picrites are not known to be represented in England, but, on the other hand, there are Devonian picrites in Devon and Cornwall as basic members of the diabase and peridotite series of these counties. None of them contains much augite like the picrite (often called palaeopicrite as being of palaeozoic age) at Menheniot Station in Cornwall and the picrite of Highweek near Newton Abbot in Devonshire. Others are hornblende-picroites like that of Cartburgh near St Germans, Cornwall. Hornblende picrites are also known in the Southern Alps of New Zealand. Some beautiful examples have been described from Anglesey and from Penafynddydd in North Wales and from Wicklow in Ireland. Picrites occur in several parts of Germany, notably in the Devonian rocks of the Harz Mountains. In France, picrites and mafic basic lavas are found in the Massif Central and in the South of France. Picrites are known in the United States from the eastern seaboard as well as from Alabama and Montana.

PICROTOXIN, a neutral principle obtained from the Cocculus indicus, which is the fruit of the Anamirta paniculata. It is used in medicine externally as an antiparasitic. Internally it has been successfully used to check the night-sweats of phthisis. In large doses it is a powerful poison, causing unconsciousness, delirium, convulsions, gastro-enteritis and stimulation of the respiratory centre followed by paralysis, from which death sometimes results. Formerly low class publicans sometimes added Cocculus indicus berries to beer to increase the intoxicating effects. Its chemical formula is C19H30O7H2O.

PICKET DE LA RIVE, FRANÇOIS JULES (1809-1872), Swiss zoologist and palaeontologist, was born in Geneva on the 27th of September 1809. He graduated B. és Sc. at Geneva in 1829, and pursued his studies for a short time at Paris, where under the influence of Cuvier, de Blainville and others, he worked at natural history and comparative anatomy. On his return to Geneva in 1830 he assisted A. P. de Candolle by giving demonstrations in comparative anatomy. Five years later, when de Candolle retired, Picket was appointed professor of zoology and comparative anatomy. In 1846 his duties were restricted to certain branches of zoology, including geology and palaeontology, and these he continued to teach until 1859, when he retired to devote his energies to the museum of natural history and to special palaeontological work. He was rector of the academy from 1847 to 1859, and again from 1866 to 1868. He was for many years a member of the Representative Council of Geneva, and from 1862 to 1864 President of the Constituent Assembly of Switzerland. His published work related chiefly to entomology, and included Recherches pour servir à l'histoire et à l'anatomie des Phrygainides (1834) and two parts of Histoire naturelle, générale et particulière des insectes Neuroptères (1842-1845). Feeling the want of a hand-book, he prepared his Traité élémentaire de paléontologie (4 vols. 1844-1846). In the first edition Pictet, while adopting the hypothesis of successive creations of species, admitted that some may have originated through the modification of pre-existing forms. In his second edition (1853-1857) he enters further into the probable transformation of some species, and discusses the independence of certain faunas, which did not appear to have originated from the types which locally preceded them. He now directed his attention to the fossils of his native country, more especially to those of the Cretaceous and Jurassic
swing partly to his naturally stern and now embittered temper, and partly to the difficult position in which he was placed, was unfortunate. On the Con in July 1810 Craufurd's division became involved in an action, and Picton, his nearest neighbour, refused to support him, as Wellington's direct orders were to avoid an engagement. Details of the incident will be found in Oman, Peninsular War, vol. iii. Shortly after this, however, at Busaco, Picton found and used his first great opportunity for distinction. Here he had a plain duty, that of repulsing the French attack, and he performed that duty with a skill and resolution which indicated his great powers as a troop-leader. After the winter in the lines of Torres Vedras, he added to his reputation and to that of his division, the 3rd, at Fuentes d'Onor.

In September he was given the local rank of lieutenant-general, and in the same month the division won great glory by its rapid and orderly retreat under severe pressure from the French cavalry at El Bodon. In October Picton was appointed to the colonelcy of the 77th regiment. In the first operations of 1812 Picton and Craufurd, side by side for the last time, stormed the two breaches of Ciudad Rodrigo, Craufurd and Picton's second in command, Major-General Loring, lost his commission.

At Badajoz, a month later, the successful storming of the fortress was due to his daring self-reliance and penetration in converting the secondary attack on the castle, delivered by the 3rd division, into a real one. He was himself wounded in this terrible engagement, but would not leave the ramparts, and the day after, having recently inherited a fortune, he gave every survivor of his command a guinea. His wound, and an attack of fever, compelled him to return to England to recruit his health, but he reappeared at the front in April 1813. While in England he was invested with the collar and badge of a K.B. by the prince regent. and in June he was made a lieutenant-general in the army. The conduct of the 3rd division under his leadership at the battle of Vittoria and in the engagements in the Pyrenees raised his reputation as a resolute and skilful fighting general to a still higher point. Early in 1814 he was offered, but after consulting Wellington declined, the command of the British forces operating on the side of Catalonia. He thus bore his share in the Orbizhe campaign and in the final victory before Toulouse.

On the break-up of the division the officers presented Picton with a valuable service of plate, and on the 24th of June 1814 he received for the seventh time the thanks of the House of Commons for his great services. Somewhat to his disappointment he was not included amongst the generals who were raised to the peerage, but early in 1815 he was made a G.C.B. When Napoleon returned from Elba, Picton, at Wellington's request, accepted a high command in the Anglo-Dutch army. He was severely wounded at Quatre Bras on the 16th of June, but concealed his wound and retained command of his troops, and at Waterloo on the 18th, while repulsing with impetuous valour "one of the most serious attacks made by the enemy on our position," he was shot through the head by a musket ball. His body was brought home to London, and buried in the family vault at St.owe. In 1829 a public monument was erected to his memory in St Paul's Cathedral, by order of parliament, and in 1823 another was erected at Carmarthen by subscription, the king contributing a hundred guineas thereto.

See Robinson's Life of Sir Thomas Picton (London, 1836), which, however, compare Napier's and Oman's histories of the Peninsular War as to controversial points.

PICTOU, a seaport, port of entry, and capital of Pictou county, Nova Scotia, 90 m. N.E. by N. of Halifax, on a branch of the Intercolonial railway. Pop. (1901), 3235. It has several valuable industries, and is the shipping port for the adjacent coal-mines. The Academy, founded in 1818, played an important part in the early educational history of the province, and still enjoys a high reputation.

PICUS, in Roman mythology, originally the woodpecker, the favourite bird and symbol of Mars as the god of both nature and war. He appears later as a spirit of the forests, endowed with the gift of prophecy, haunting springs and streams, with a special sanctuary in a grove on the Aventine. As a god of agriculture, especially connected with manuring the soil, he is called the son of Stercucus (from stericus, dung, a name of Saturn). Again, Picus is the first king of Latium, son of Saturn and father of Fannus. Virgil (Aen. vii. 170) describes the reception of the ambassadors of Aeneas by Latins in an ancient temple or palace, containing figures of his divine ancestors, amongst them Picus, famous as an augur and soothsayer. According to Ovid (Metam. xiv. 320), Circe, while gathering herbs in the forest, saw the youthful hero out hunting, and immediately fell in love with him. Picus rejected her advances, and the goddess in her anger changed him into a woodpecker, which pecks impotently at the branches of trees, but still retains prophetic powers. The purple cloak which Picus were fastened by a golden clasp is preserved in the plumage of the bird. In the simplest form of art, he was represented by a wooden pillar surmounted by a woodpecker; later, as a young man with the bird upon his head.

PICNUMUS is merely another form of Picus, and with him is associated his brother and double PICTUMUS. Picumnus, a rustic deity (like Picus) and husband of Pomona, is specially concerned with the manuring of the soil and hence called Sterculinus, while Plumnus is the inventor of the pounding of grain, so named from the pestle (pilum) used by bakers. Under a different aspect, the two were regarded as the guardians of women in childbirth and of new-born children. Before the child was taken up and formally recognized by the father, a couch was set out for them in the atrium, where their presence guarded it from all evil. Augustine (De civ. deum, vi. 25) makes a mortal woman in childbirth from possible violence on the part of Silvanus, the assistance of three deities was invoked—Intercedidona (the healer), Plumnus (the pounder) and Deverra (the sweeper). These deities were symbolically represented by three men who went round the house by night. One smote the threshold with an axe, another with a pestle, the third swept it with a broom—three symbols of culture (for trees were hewn down with the axe, grain pounded with the pestle, and the fruits of the field swept up with the broom) which Silvanus could not fail to recognize.

PIDGIN [or PICGEN] ENGLISH, the lingua franca of the sea ports of China, the Straits Settlements in the Far East, consisting in a jargon of corrupted English words with some intermixture of Portuguese and Malay, following Chinese idiomatic usage. It is employed as a means of communication between foreigners and the native Chinese. The word "pidgin" is the Chinese corruption of "business."

PIE. (1) The name of the bird more generally known as the magpie (q.v.). The word comes through the French from Lat. pica (q.v.). It is probably from the black and white or spotted appearance of the bird that the name "pie" or "pye" (Lat. pica) was given to the ordinal, a table or calendar which supplemented that which gave the services for the fixed festivals, &c., and pointed out the effect on them of the festivals rendered movable by the changing date of Easter. An English act of 1549 (3 & 4 Edw. VI. c. 10) abolished "pies" with manuals, legends, primers and other service books. The parti-coloured appearance of the magpie also gives rise to the term "piebald," applied to an animal, more particularly a horse, which is marked with white and black patches of irregular form, while the colour is white and some colours other than black, the more irregular the appropriate word is "skew-bald," i.e. marked with "skew" or irregular patches. (2) A dish made of meat, fish or other ingredients, also of vegetables or fruit, baked in a covering of pastry; in English usage, where "fruit" is the ingredient, the dish is generally called a "tart," except in the case of "apple-pie."

The word appears early in the 14th century of meat or fish pies.

The expression "to eat humble-pie," i.e. to make an apology, to retract or recant, is a facetious adaptation of "umbles" (O. Fr. nombles, connected with Lat. lumbus, loin or umbilicus, navel), the inner parts of a deer, to "humble" (Lat. humilis, lowly). An "umble-pie," made of the inner parts of a deer or other animal, was once a favourite dish. "Printers' pie," i.e. a mass of confused type, is a transferred sense of "pie," the dish, or of "pie," the ordinal, from the difficulty of decipherment.

PIEDMONT (Ital. Piemonte; Low Lat. Pedomens and Pede- montium), a territorial division (compartimento) of northern
PIENZA—PIER

Italy, bounded N. by Switzerland, W. by France, S. by Liguria and E. by Lombardy. Physically it may be briefly described as the upper gathering-ground and valley of the river Po, enclosed on all sides except towards the Lombard plain by the vast semicircle of the Pennine, Graian, Cottian, Maritime and Ligurian Alps. In 1859 it was divided into the four provinces of Alessandria, Cuneo, Novara and Torino (Turin). It has an area of 11,340 sq. m. The people are chiefly engaged in agriculture—growing wheat, maize and rice, chestnuts, wine and hemp; in the reeling and throwing of silk and in the manufacture of cotton, woollens and clothing; there are also considerable manufactures at Turin, Savigliano, &c. The Piedmontese dialect has been rather strongly influenced by French. The chief towns in the several provinces are as follows, with their communal populations in 1901: Alessandria (72,105), Asti (93,375), Casale Monferrato (31,570), Novi Ligure (17,868), Tortona (17,419), Acqui (13,940), Valenza (10,936), Ovada (10,843); total of province 825,745; number of communes 343; Cuneo (26,870), Mondovì (18,982), Fossano (18,175), Savigliano (17,340), Saluzzo (16,028), Brà (15,821), Alba (13,657), Boves (10,187); total of province 670,504, number of communes 263; Novara (44,249), Ivrea (17,703), Trino (13,883), Bondoni (10,131); total of province 763,830; number of communes, 437; Turin (329,691), Fierole (18,939), Carmagnola (11,721), Ivrea (11,606), Moncalieri (11,467); total of province 1,147,414; number of communes, 442. The total population of Piedmont was 2,738,814 in 1859, and in 1901 3,407,493. The large number of communes is noticeable, as in Lombardy, and points to a village life which, owing to greater insecurity and the character of the country, is not to be found in central and southern Italy as a whole. There are numerous summer resorts in the Alpine valleys. The chief railway centres are Turin, communicating with the Mont Cenis line, and with the Riviera by the railway over the Col di Tenda in process of construction; Novara, Vercelli, Asti, Alessandria, Novi. The communications with Liguria are difficult owing to the approach of the mountains to the coast, and the existing lines from Genoa to Turin and Milan are hardly sufficient to cope with the traffic. Piedmont in Roman times until 40 B.C. formed a part of Gallia Transpadana, and in Augustus' division of Italy formed with what was later known as Lombardy the 11th region. It formed part of the Lombard kingdom, and it was not till about a.d. 1000 that the house of Savoy (q.e.) arose. The subsequent history of Piedmont is that of its dynasty.

PIENZA, a town of Tuscany, Italy, in the province of Siena, 9 m. west of the town of Montepulciano by road, 1,611 ft. above sea-level. Pop. (1901), 2730 (town); 3836 (commune). The place was originally called Corisignano and owes its present name to Aeneas Silvius Piccolomini, Pope Pius II. (q.e.) who was born here in 1405. The buildings which he caused to be erected by Bernardo Rossellino in 1460-1463 form a noble group of early Renaissance architecture round the Piazza del Duomo. The latter retains Gothic details in the interior, but the façade is simple Renaissance work. The other three sides are occupied by the episcopal and municipal palaces, and the Palazzo Piccolomini; the last, resembling the Palazzo Rucellai at Florence, is the finest, and in front of it is a beautiful fountain. The episcopal palace contains a museum with some fine ecclesiastical vestments, enamels and other works of art.

PIER (older forms per or pere, from Med. Lat. pere; the word is of obscure origin, and the connexion with Fr. pierre, Lat. petra, stone, is doubtful; equivalents are Fr. piedrot, pilier, troncous; Ital. pila; Ger. Pfeller), the term given in architecture to a vertical support in masonry or brickwork, usually rectangular on plan, which carries an arch or superstructure. The term is also sometimes given to the great circular columns which in some English cathedrals and churches carry the nave arches. In early Christian churches, when antique columns, such as abounded in Rome, were not procurable, square piers took the place of columns and sometimes alternated with them. The introduction of vaulting, however, in the 11th century, necessitated a support of much greater dimensions than those which had been deemed sufficient when the roof was of timber only, and led to the development of the compound or clustered pier. To give extra support to the subordinate arches of the nave arcade, semicircular shafts or pilasters were added, carried up to the transverse and diagonal ribs of the main vault. In Romanesque work the pier was generally square on plan with semicircular shafts attached, the angles of the pier being worked with smaller shafts. As the rings or orders of the nave arches increased in number, additional shafts were added to carry them, and the pilaster facing the nave had central and side shafts rising to carry the transverse and diagonal ribs of the vault; this development of the compound pier obtains throughout Europe in all vaulted structures. In the Early English period the piers become loftier and lighter, and in most important buildings a series of clustered columns, frequently of marble, are placed side by side, sometimes set at intervals round a circular centre, and sometimes almost touching each other. These shafts are often wholly detached from the central pier, though grouped round it, in which case they are almost always of Purbeck or Bathersden marbles. In Decorated work the shafts on plan are very often placed round a square set angle-wise, or a lozenge, these piers grouped round the nave and wider shafts often worked into hollows or other mouldings, to show between the shafts, and to form part of the composition. In this and the latter part of the previous style there is generally a fillet on the outer part of the shaft, forming what has been called a "keel moulding" (q.e.). They are also often tied together by bands, formed of rings of stone and sometimes of metal. About this period, too, these intermediate mouldings run up into and form part of the arch moulds, there being no impost. This arrangement became much more frequent in the Perpendicular period; in fact it was almost universal, the commonest section being a lozenge set with the long side from the nave to the aisle, and not towards the other arches, as in the Decorated period, with four shafts at the angles, between which were shallow mouldings, one of which was in general a wide hollow, sometimes with wave moulds. The small columns at the jambds of doors and windows, and in arcades, and also those attached to piers or standing detached, are generally called "shafts" (q.e.).

The term pier is sometimes applied to the solid parts of a wall between the windows or arches, and also to the isolated masses of brickwork or masonry to which gates are hung. (R. P. S.)

Piers of Bridges.—The piers of bridges and viaducts on land are constructed of masonry or brickwork and occasionally, in the case of high piers, of open-braced ironwork, as exemplified by the old Crumlin viaduct in Wales and the Pecos viaduct in Texas. These piers, besides being proportioned in cross-section to the weight they have to support, are widened out at their base, so as to distribute the load over a sufficient area for it to be borne by the stratum on which it rests without risk of settlement. Special provisions have to be made for the foundations of piers where the ground is soft for some depth, or loose water-bearing strata are encountered, and especially where the piers of large bridges crossing rivers have to be constructed under water. In soft ground, bearing piles driven down to a firm stratum, and surmounted by a planked floor or a layer of concrete, provide a convenient foundation for a pier; and in places where timber is abundant, wooden cribs filled with rubble stone or concrete were used in the United States for raising the foundations for piers out of water. For river piers, where a firm watertight stratum is found at a moderate depth below the river-bed, the site is often enclosed within a coffer-dam or a plate iron caisson carried down into the stratum and raised out of water; and then, after the water has been pumped out and the surface layers removed, the pier is readily built within the enclosure in the open air. When, however, a river-bed consists of silt, sand or other soft materials extending down to a considerable depth, brickwork wells are gradually sunk to a firm stratum by removing the material within them with grabs, and on the piers are built out of water; or bottomless caissons are carried down by excavating their interiors under compressed air, and the piers are built on top of them within a plate-iron enclosure, a system
adopted for the piers of the Brooklyn, St Louis, Forth and other large bridges, and essential for forming foundations on sloping rock, such as was encountered in places under the Firth of Forth.

The methods indicated above as employed for the foundations of the piers of bridges under favourable conditions belong equally to the foundations of other structures (see Foundations); but there are some methods which, by combining bridge piers and their foundations in a single structure, appertain entirely to piers. Thus iron screw piles, sunk by turning into the soft bed of a river till they reach a firm stratum or one sufficiently consolidated by the superincumbent layers to enable it to support the wide blades of the screws with the weight imposed on them, were formerly often arranged in converging clusters joined together at the top, so as to serve as the piers of bridges having several comparatively small spans, and intended for carrying lightly constructed railways across rivers in India and elsewhere. Hollow, cast-iron, cylindrical piles also, with a broad circular disk at the bottom to increase their bearing surface, have been used for piers founded in sandy or silty strata of considerable thickness; they are sunk to the requisite depth by lowering a pipe down the inside of the pile to the bottom and emitting a powerful jet of water which, stirring up the soft material and scouring it away from under the disk, causes the pile to descend. This system was first adopted for the piers of a railway viaduct crossing the wide, sandy Kent and Leven estuaries opening into Morecambe Bay (fig. 1). Cast-iron cylinders, consisting of a series of rings formed of segments all bolted together with a specially strong bottom ring, sometimes made of wrought iron and having a cutting edge, have been often employed for the construction of the river piers of bridges, being gradually carried down to a watertight stratum by excavating inside, and subsequently filled up solid with concrete and brickwork; the piers of the Charing Cross and Cannon Street bridges across the Thames are notable instances of the adoption of this method, which is well illustrated by the piers of the bridges across the River Chitravati in India (fig. 2). Sometimes, instead of two or more independent cylinders being sunk, the whole site of a pier is enclosed within a wrought-iron caisson, usually divided into sections by vertical partitions, which is sunk and filled up solid in the same way as cylinders, a system adopted, for instance, for the piers of the bridge across the Hawkesbury River in New South Wales.

Promenade Piers.—The term is often applied to works sheltering harbours, such as the Tynemouth piers, which are strictly breakwaters. Landing stages also, whether solid or open, have for a long time been called piers, as the Admiralty Pier and the Prince of Wales’s Pier at Dover; but the open promenade piers which form a common feature at seaside resorts are the type of pier best known to the general public. These piers are supported upon open pilework of timber or iron, and consequently expose little surface to waves in storms and do not interfere with the drift of shingle or sand along the coast (fig. 3). Timber piles are best suited for withstanding the shocks of vessels at landing stages, at which places they are generally used; but since they are subject to the attacks of the teredo, and expose a considerable surface to the waves, iron piles are generally adopted for the main portion of these piers.

The pioneer of these piers was the old chain pier at Brighton, which was erected in 1822-1825. It was founded upon oak piles, was 1136 ft. long, and had a timber landing-stage at the end. It consisted of four spans suspended from chains on the model of the Menai Suspension Bridge, then in course of construction, and was destroyed by a gale in December 1896. A wider and more modern type of pier was erected at the west end of Brighton in 1865-1866, and subsequently extended; whilst a new pier was completed in 1900 near the site of the old chain pier. 1700 ft. long. The Southport pier, erected in 1859-1860 and afterwards prolonged, furnishes an example of an iron pier supported on disk piles sunk in sand as described above (fig. 1); whilst the much more commonly used iron screw piles, adopted as early as 1847 for an open landing-pier on the Irish coast at Courtown, which was exposed to a great littoral drift of sand, are shown as the mode of support for the pier.
at St. Leonards (fig. 3). The length given to these promenade
piers depends mainly on the slope of the foreshore, which
determines the distance from the shore at which a sufficient depth
is reached for steamers of moderate draught to come alongside
the end of the pier. Thus, whereas a length of 900 ft. has sufficed
for the St. Leonards pier on a somewhat steep, shingly beach, the
pier at Ryde, constituting the principal landing-place for the Isle of
Wight passengers, has had to be carried out about half a mile across
a flat alluvial foreshore to reach water deep enough for the access
of the steamboats crossing the Solent. The vast sands, moreover,
at the outlet of the Ribble estuary, stretching two or three miles
in front of Southport at low water of spring tides, have necessitated
the construction of a pier 4395 ft. long merely to get out to an
old sand-bank, which is otherwise covered by the sands at low water from all connexion with the river.

Pierce, Franklin (1804—1869), fourteenth president of
the United States, was born at Hillsborough, New Hampshire,
the 23rd of November 1804. His father, Benjamin Pierce
(1757—1839), served in the American army throughout the War
of Independence, was a Democratic member of the New Hamp-
shire House of Representatives from 1789 to 1803, and was
governor of the state in 1827—1829. The son graduated in 1824
at Bowdoin College, at Brunswick, Maine, where he formed a
friendship with Nathaniel Hawthorne. Pierce then studied law,
and in 1827 was admitted to the bar and began, to practise
at Hillsborough. He at once took a lively interest in politics,
and from 1828 to 1833 served in the New Hampshire House of
Representatives for six of these years as Speaker. In 1833 he
entered the national House of Representatives, and although he
achieved no distinction in debate he was a hard worker, and a loyal sup-
porter of the policies of President Jackson. After four years
in the House he entered the Senate, being its youngest member.
In 1842, before the expiration of his term, he resigned his seat,
and at Concord, New Hampshire, began his career at the bar in
earnest, though still retaining an interest in politics. In 1845
he declined the Democratic nomination for governor, and also
an appointment to the seat in the United States Senate made
vacant by the resignation of Judge Levi Woodbury. He
accepted, however, an appointment as Federal District Attorney
for New Hampshire, as the duties of this office, which he held in
1845—1847, were closely related to those of his profession. In
1846 he again declined public honours, when President Polk
invited him to enter the cabinet as attorney-general. Soon
after the outbreak of the war with Mexico, in 1846, Pierce
enlisted as a private at Concord, but soon (in February 1847)
became colonel of the Ninth Regiment (which joined General
Ward's army) and then colonel (April 1847) and (March, 1847)
became a brigadier-general of volunteers. At the battle of Contreras, on the 10th of August 1847, he was thrown from
his horse and received severe injuries. At the end of the war
he resigned his commission and returned to Concord.
In 1850 Pierce became president of a convention assembled at
Concord to revise the constitution of his state, and used his
influence to secure the removal of those provisions of the con-
sitution of 1792 which declared that only Protestants should be
eligible for higher state offices. This amendment passed the
convention in April 1852, but was rejected by the electorate of
the state; a similar amendment was adopted by popular vote in
1877. In January 1852 the legislature of New Hampshire
proposed him as a candidate for the presidency, and when the
Democratic national convention met at Baltimore in the follow-
ing June the Virginia delegation brought forward his name on
the thirty-fifth ballot. Although both parties had declared
the Compromise of 1850 a failure, the Democrats alone were
thoroughly united in support of this declaration, and therefore
seemed to offer the greater prospect of peace. This fact, com-
bined with the colourless record of their candidate, enabled
them to sweep the country at the November election. Pierce
received 254 electoral votes, and General Winfield Scott, his
Whig opponent, only 42. The Democrats carried every state
except Massachusetts, Vermont, Kentucky and Tennessee. No
president since James Monroe had received such a vote.

Pierce was the youngest man who had as yet been elevated
to the presidency. For his cabinet he chose William L. Marcy
of New York, secretary of state; Jefferson Davis of Mississippi,
secretary of war; James Guthrie (1792—1869) of Kentucky,
treasurer of the Confederate States; James D. Dobbin (1815—1877) of
North Carolina, secretary of the navy; Robert McClelland
(1807—1889) of Michigan, secretary of the interior; James
Campbell (1813—1893) of Pennsylvania, postmaster-general;
and Caleb Cushing of Massachusetts, attorney-general. This
was an able body of men, and is the only cabinet in American
history that has continued unbroken throughout an entire
administration. Although Pierce during his term in the Senate
had severely criticized the Whigs for their removals of Demo-
crats from office, he himself now adopted the policy of replacing
Whigs by Democrats, and the country acquiesced. Pierce had
no scruples against slavery, and opposed anti-slavery agitation
as tending to disrupt the Union. The conduct of foreign
relations was on the whole the most creditable part of his admin-
istration. The Koszta Affair (1853) gave the government an
opportunity vigorously to assert the protection it would afford
those in the process of becoming its naturalized citizens. When
the British government refused to prevent recruiting for the
Crimean War by their representatives in America, their minister,
John F. Crampton, received his passports, and the exequaturs
of the consuls of France, Germany, and others were also re-
volved. A commercial treaty was negotiated with Japan
in 1854 after Perry's expedition in the previous year. As
an avowed expansionist, Pierce sympathized with the filibuster
government set up in Nicaragua by William Walker, and finally
accorded it recognition. It was during this term also that the
Gadsden Purchase was consummated, by which 45,535 sq. m.
of territory were acquired from Mexico, and that three routes
were surveyed for railways from the Mississippi river to the Pacific
coast.

When the Democratic national convention met at Cincin-
ti in June 1856, Pierce was an avowed candidate for renomina-
tion, but as his attitude on the slavery question, and especially his
subserviency to the South in supporting the pro-slavery party
in the Territory of Kansas, had lost him the support of the Northern wing of his party, the nomination went to James
Buchanan. After retiring from the presidency Pierce returned
to Concord, and soon afterwards went abroad for a three years'
tour in Europe. Many Southern leaders desired his renomina-
tion by the Democratic party in 1860, but he received such
suggestions with the greatest reluctance. After his return to America he remained in retirement at Concord until the day of his death,
the 8th of October 1869.

Pierce was not a great statesman, and his fame has been
overshadowed by that of Benton, Calhoun, Clay and Webster.
But he was an able lawyer, an orator of no mean reputation,
and a brave soldier. He was a man of fine appearance and
courtly manners, and he possessed personal magnetism and the
ability to make friends, two qualities that contributed in great
measure to his success.

A portion of Pierce's correspondence has been published in
the American Historical Review, x. 119—127, 350—370. D. W. Barlett's
Pierce (New York, 1893); and Haw-
thorne's Franklin Pierce (Boston, 1852), are two "campaign
biographies," and are very eulogistic. J. R. Irelan's History of the
Life, Administration and Times of Franklin Pierce (Chicago, 1888),
remains the best book on Pierce, as it is a critical work, but inac-
quate as to details. J. E. Cooley's Review of the Administration of
General Pierce (New York, 1854) and Anna E. Carroll's Review
of Pierce's Administration (Boston, 1859) are hostile anti-administra-
tion tracts. The best accounts of Pierce's administration are
found in James Schouler's History of the United States, vol. v. (new
ed., New York, 1894); J. F. Rhodes's History of the United States,
vols. i. and ii. (New York, 1893—1894); and J. W. Burgess's Middle
Pod (New York, 1900).

Piero di Cosimo (1496—1524), the name by which the Flo-
tentine painter Pietro di Lorenzo is generally known. He
was born in Florence about 1496, and worked in the bottega
of Cosimo Rosselli (from whom he derived his popular name).
Other influences that can be traced in his work are those of
Filippino Lippi, Luca Signorelli, and Leonardo da Vinci, and,
as has been recently suggested by Professor R. Muther, that of
Hugo van der Goes, whose Portinar altarpiece (now at the

590
Spedale of S. Maria Novella in Florence) helped to lead the whole of Florentine painting into new channels. From him, most probably, he acquired the love of landscape and the intimate knowledge of the growth of flowers and animal life. The influence of Hugo van der Goes is especially apparent in the "Adoration of the Shepherds," at the Berlin Museum. He had the gift of a fertile imaginative vision, which, as a result of a journey to Rome in 1482 with his master, Roselli, became directed towards the myths of classic antiquity. He proved himself a true child of the Renaissance in such pictures as the "Death of Procris," at the National Gallery, the "Mars and Venus," at the Berlin Gallery, the "Perseus and Andromeda" series, at the Uffizi in Florence, and the "Hylas and the Nymphs" belonging to Mr Benson. If, as we are told by Vasari, he spent the last years of his life in gloomy retirement, the change was probably due to Savonarola, under whose influence he turned his attention once more to religious art. The "Immaculate Conception," at the Uffizi, and the "Holy Family," at Dresden, best illustrate the religious fervor to which he was stimulated by the stern preacher.

With the exception of the landscape background in Roselli's fresco of the "Sermon on the Mount," in the Sistine Chapel, we have no record of any fresco work from his brush. On the other hand, he enjoyed a great reputation as a portrait painter, though the only known examples that can be definitely ascribed to him are the portrait of a warrior, at the National Gallery, (No. 805), the so-called "Bella Simonetta," at Chantilly, the portraits of Giuliano di San Gallo and his father, at the Hague, and a head of a youth at Dulwich. Vasari relates that Piero excelled in designing pageants and triumphal processions for the pleasure-loving youths of Florence, and gives a vivid description of one such procession at the end of the carnival of 1507, which illustrated the triumph of death. Piero di Cosimo exercised considerable influence upon his fellow pupils Albertinelli and Bartolommeo della Porta and was the master of Andrea del Sarto. Examples of his work are also to be found at the Louvre in Paris, the Hærach and Liechtenstein collections in Vienna, the Borghese Gallery in Rome, the Spedale degli Innocenti in Florence, and the collections of Mr John Burke and Colonel Cornwallis West in London. A "Magdalene" from his brush was added to the National Gallery in 1907; see Piero di Cosimo, by F. Knapp (Halle, 1899); Piero di Cosimo, by H. Haberfeld (Breslau, 1905).

PIERRE, the capital of South Dakota, U.S.A., and the county-seat of Hughes county, situated on the east bank of the Missouri river, opposite the mouth of the Bad river, about 183 miles northwest of Sioux City, Iowa; pop. (1900) 2,704; est. 1858. Pierre is served by the Chicago & North-Western railway; the Missouri is navigable here, but river traffic has been practically abandoned. Among the principal buildings are the state capitol (1899) and the post office building. Pierre has a public library, and is the seat of the Pierre Industrial School (co-educational, opened in 1890), a government boarding school (non-reservation) for Indian children. The city has a large trade in livestock, and is a centre for the mining districts of the Black Hills and for a grain-growing country. Natural gas is used for lighting, heating and power. A fur-trading post, Fort La Framboise, was built in 1817 by a French fur-trader (from whom it took its name) at the mouth of the Teton or Little Missouri river (now called the Bad River), on or near the site of the present village of Fort Pierre (pop. in 1910, 702). In 1822 Fort Tecumseh was built about 2 m. up-stream by the Columbia Fur Company, which turned it over in 1827 to the American Fur Company. The washing away of the river bank caused the abandonment of this post and the erection about a mile farther up-stream, and a short distance west of the river, of Fort Pierre Chouteau (later called Fort Pierre), occupied in 1832, and named in honour of Pierre Chouteau, jun. (1758-1865). For twenty years thereafter Fort Pierre was the chief fur-trading depot of the Upper Missouri country. In 1855 the United States government bought the post building and other property for $45,000, and of course abandoned it. Its site is not more than 2 sq. m. The fort was the headquarters of General William S. Harney (1800-1889) in his expedition against the Sioux in 1856, and in March of that year an important council between General Harney and the chiefs of all the Sioux bands, except the Blackfeet, was held here. The fort was abandoned in 1857. Pierre was laid out in 1880, was incorporated as a village in 1883, and was chartered as a city in 1900.

PIERRE DE CASTELNAU (d. 1208), French ecclesiastic, was born in the diocese of Montpellier. In 1190 he was archdeacon of Maguelonne, and was appointed by Pope Innocent III. as legate for the suppression of heresy in Languedoc. In 1202, when a monk in the Cistercian abbey of Fontfroide, Narbonne, he was designated to similar work, first in Toulouse, and afterwards at Viviers and Montpellier. In 1207 he was in the Rhone valley and in Provence, where he became involved in the strife between the count of Baux and Raymond, count of Toulouse, by one of whose agents he was assassinated on the 15th of January 1208. He was beatified in November of his year by the death of Pope Innocent III.

See De la Bouilleure, Le Bienheureux Pierre de Castelnaul et les Abbeges au XIII. siecle (Paris, 1866).

PIERFONDS, a town of northern France, in the department of Oise, 9 m. S.E. of Compiègne by road. Pop. (1906) 1,842. It is celebrated for its feudal stronghold, a masterpiece of modern restoration. The building is rectangular in shape, with a tower at each corner and at the centre of each of the walls, which are strengthened by crenelation and machicolation. A lofty keep defends the principal entrances on the south-west. The interior buildings are chiefly modern, but the exterior reproduces faithfully that of the medieval fortress. Pierfonds has a church dating from various periods from the 11th to the 16th century, and its mineral springs are in some repute. The chateau was begun in the last decade of the 14th century by Louis I. of Bourbon, to whom the domain was given by Charles VI. and finished early in the 15th century. It subsequently held by the Burgundians, the English and the adherents of the League, from whom it passed to Henry IV. It was dismantled in 1622. The ruins, bought by Napoleon I., were restored, by order of Napoleon III., from 1858 to 1865, under the direction, first of Viollet-le-Duc and afterwards of E. Boeswillwald.

PIERREPONT, WILLIAM (c. 1607-1678), English politician, was the second son of Robert Pierrepont, 1st earl of Kingston. Returned to the Long Parliament in 1640 as member for Great Wenlock, he threw his influence on the side of peace and took part for the parliament in the negotiations with Charles I. at Oxford in 1643. Pierrepont was a member of the committee of both kingdoms, and represented the parliamentary party during the deliberations at Uxbridge in 1645; but from that time, according to Clarendon, he forsook his moderate attitude, and "contracted more bitterness and sorrorness than formerly." This statement, however, is perhaps somewhat exaggerated, as Pierrepont favoured the resumption of negotiations with the king in 1647, and in the following year his efforts on behalf of peace at Newport, where again he represented the parliamentarians, brought upon him some slight censure from Cromwell. For his services at Newport, he was thanked by parliament; but he was later suspended from public affairs, as he had disliked the "purging" of the House of Commons by Colonel Pride and the proceedings against the king. In spite of his Company. Chouteau built (in 1830-1831) the "Yellowstone," which went up the river to the present site of Pierre in 1831, and was the first steamboat to navigate the upper waters of the Missouri. Chouteau lived for some years in New York City, and while living in St Louis was a member of the convention (1820) which drafted the first constitution of Missouri.
PIERROT—PIETERSBURG

moderate views Pierrepont enjoyed the personal friendship of Cromwell; but, although elected, he would not sit in the parliament of 1676, nor would he take the place offered him in the Protector’s House of Lords. When Richard Cromwell succeeded his father, Pierrepont was an unobtrusive but powerful influence in directing the policy of the government, and after a short period of retirement on Richard’s fall he was chosen, early in 1660, a member of the council of state. He represented Nottinghamshire in the Convention Parliament of 1660, and probably was instrumental in saving the lives of some of the parliamentary leaders. At the general election of 1661 he was defeated, and, spending the remainder of his life in retirement, he died in 1678. Pierrepont married Elizabeth, daughter of Sir Thomas Harris, Bart., of Tong Castle, Shropshire, by whom he had five sons and five daughters. His eldest son, Robert (d. 1666), was the father of Robert, 3rd earl, William, 4th earl, and Evelyn, 1st duke of Kingston; and his third son, Gervase (1649–1715), was created in 1714 baron Pierrepont of Halslope, a title which became extinct on his death.

PIERROT (Kai Pedrotino), the name given to the leading characters in the French pantomime plays since the 18th century, transferred from the Italian stage, and revived especially in recent times. He is always in white, both face and costume, with a loose and daintily clownish garb, and is represented as of a freakish disposition. Modern pierrot plays have converted the pierrot into a romantic and even pathetic figure.

PIERSON, HENRY HUGO [properly Henry Hugh Pearson], (1815–1873), English composer, was the son of the Rev. Dr. Pearson of St John’s College, Oxford, where he was born in 1815; his father afterwards became dean of Salisbury. Pierson was educated at Harrow and Trinity College, Cambridge, and was at first intended for the career of medicine. His musical powers were too strong to be repressed, and after receiving instruction from Attwood and A. T. Corfe he went in 1839 to Germany to study under C. H. Rink, Tomàsche and Reissiger. He was elected Reid Professor of Music in Edinburgh in 1844, but, owing to a disagreement with the authorities, he resigned the following year, and definitely adopted Germany as his country about the same time, making the change in his names noted above. His two operas, Leila (Hamburg, 1848) and Contarint (Hamburg, 1872), have not retained their hold upon the German public as his music to Faust has done, a work which until quite recently was frequently associated with Goethe’s drama. He was never recognized in England as he was in Germany, for most of his career fell in the period of the Mendelssohn fashion. His most important work was the oratorio Jerusalem, produced at the Norwich Festival of 1852, and subsequently given in London (Sacred Harmonic Society, 1853) and Würzburg (1862). For the Norwich Festival (at one of the meetings a selection from his Faust music was given with success) he began an oratorio, Hezekiah, in 1860; it was not finished, but was given in a fragmentary condition at the festival of that year. These two large works and a number of Pierson’s songs, as well as the three overtures played at the Crystal Palace, reveal undeniable originality and a wealth of melodic fancy. His instrumental skill and his ability at writing in outline and coherence; but in more fortunate conditions his great gifts might have been turned to better account. He died at Leipzig on the 28th of January 1873, and was buried at Sonning, Berks., of which parish his brother, Canon Pearson, was rector.

PIETAS, in Roman mythology, the personification of the sense of duty towards God and man and the fatherland. According to a well-known story, a young woman in humble circumstances, whose father (or mother) was lying in prison under sentence of death, without food, managed to gain admittance, and fed her parent with milk from her breast. To commemorate her filial affection a temple was dedicated (181 B.C.) by Manius Acilius Glabrio to Pietas in the Forum Holitorium at Rome, on the spot where the young woman had formerly lived. The temple was probably originally vowed by the elder Glabrio out of gratitude for the pietas shown during the engagement by his son, who may have saved his life, as the elder Africanus that of his father at the battle of Ticinum (Liv. xv. 46); the legend of the young woman (borrowed from the Greek story of Mycon and Pero, Val. Max. v. 4, ext. 7) was then connected with the temple by the identification of its site with that of the prison. There was another temple of Pietas near the Circus Flaminius, which is connected by Amatucci (Rivista di storia antica, 1903) with the story of the pietas of C. Flaminius (Val. Max. v. 4, 5), and regarded by him as the real seat of the cult of the goddess, the Pietas of the sanctuary dedicated by Glabrio being a Greek goddess. Pietas is represented on coins as a matron throwing incense on an altar, her attribute being a stork. Typical examples of “piety” are Aeneas and Antoninus Pius, who founded games called Eusebia at Puteoli in honour of Hadrian.

See Val. Max. v. 4; 7; Pliny, Nat. hist. vii. 121; Livy xlv. 34; Festus, s.v.; G. Wissowa, Religion und Kultus der Römer (1902); K. Zittel, “The Legemana von der guten Tochter,” in Jahrbiicher für das klassische Altertum (1904), xxiii. 280.

PIETERMARITZBURG, the capital of Natal, situated in 29° 46’ S., 30° 13’ E., 45 m. in a direct line (71 ft) by rail W.N.W. of Durban. It lies, 2,200 ft. above the sea, north of the river Umsunduzi, and is surrounded by wooded hills. Of these the Town Hill, flat-topped, rises 1600 ft. above the town. Pop. (1904), 31,110; of whom 15,087 were whites, 10,752 Kaffirs, and 5280 Indians. The town is laid out on the usual Dutch South African plan—in rectangular blocks with a central market square. The public buildings include the legislative council chambers and the legislative assembly buildings, government house, the government offices, college, post office and market buildings. The town-hall, a fine building in a modified Renaissance style (characteristic of the majority of the other public buildings), has a lofty tower. It was completed in 1901, and replaces a building destroyed by fire in 1898. St Saviour’s is the cathedral church of the Anglican community. The headquarters of the Dutch Reformed Church are also in the town. There are monuments of Queen Victoria and Sir Theophilus Shepstone, and Zoutewaal “The Legemana von der guten Tochter,” one commemorating those who fell in Zululand in 1879, and another those who lost their lives in the Boer War 1899–1902. A large park and botanical gardens add to the attractions of the town. A favourite mode of conveyance is by rickshaw. The climate is healthy and agreeable, the mean annual temperature being 65° F. (35° in June, 76° in February). The rainfall is about 38 in. a year, chiefly in the summer months (Oct.–Mar.), when the heat is tempered by violent thunderstorms.

Pietermaritzburg was founded early in 1839 by the newly-arrived Dutch settlers in Natal, and its name commemorates two of their leaders—Piet Retief and Gerrit Maritz. From the time of its establishment it was the seat of the Volksraad of the Natal Boers, and on the submission of the Boers to the British in 1842 Maritzburg (as it is usually called) became the capital of the country. It was given a municipal board in 1848, and in 1854 was incorporated as a borough. Railway connexion with Durban was made in 1880, and in 1895 the line was extended to Pretoria. The town is now served by nine railways, each covering 44,811 m. and is connected by numerous attractive suburbs. The rateable value is about £4,000,000. Various industries are carried on, including brick-making, tanning, brewing, and cart and wagon building.

See J. F. Ingram, The Story of an African City (Maritzburg, 1898).

PIETERSBURG, a town of the Transvaal, capital of the Zoutpansberg district, and 177 m. N.N.E. of Pretoria by rail. Pop. (1904), 3276, of whom 1620 were whites. The town is pleasantly situated, at an elevation of 4200 ft., on a small tributary of the Zand river affluent of the Limpopo, and is the place of most importance in the province north of Pretoria. From it roads run to Klein Lebala and other gold-mining centres in the neighbourhood, and through it passes the old route to Mashonaland, which crosses the Limpopo at Rhodes Drift. The Zoutpansberg district contains a comparatively dense Kaffir population, and a native newspaper is published at Pietersburg.
PIETISM, a movement in the Lutheran Church, arose towards the end of the 17th and continued during the first half of the following century. The name of Pietists was given to the adherents of the movement by its enemies as a term of ridicule, like that of "Methodists" somewhat later in England. The Lutheran Church had, in continuing Melanchthon's attempt to construct the evangelical faith as a doctrinal system, by the 17th century become a creed-bound theological and sacramentarian institution, which orthodox theologians like Johann Gerhard of Jena (d. 1637) ruled with almost the absolutism of the papacy. Christian faith had been dismissed from its seat in the heart, where Luther had placed it, to the cold regions of the intellect. The dogmatic formulaires of the Lutheran Church had usurped the position which Luther himself had assigned to the Bible alone, and as a consequence only they were studied and preached, while the Bible was neglected in the family, the study, the pulpit and the university. Instead of advocating the priesthood of all believers, the Lutheran pastors had made themselves a despotic hierarchy, while they neglected their practical pastoral work. In the Reformed Church, on the other hand, the influence of Calvin had made less for doctrine than the practical formation of Christian life. The presbyterian constitution established in Scotland enabled the Reformed Church of the United Provinces to make a remarkable advance, which Lutherans lacked, but it involved a dogmatic legalism which imperilled Christian freedom and fostered self-righteousness.

As forerunners of the Pietists in the strict sense, not a few earnest and powerful voices had been heard bewailing the shortcomings of the Church and advocating a revival of practical and devout Christianity. Amongst them were Jakob Boehme (Behmei), the theosophic mystic; Johann Arndt, whose work on True Christianity became widely known and appreciated; Heinrich Müller, who described the font, the pulpit, the confessional and the altar as the four dumb idols of the Lutheran Church; the theologian, Johann Valentin Andrea, the court chaplain of the landgrave of Hesse; Schuppert, who sought to restore to the Bible its place in the pulpit; and Theophilus Grossgebauer (d. 1661) of Rostock, who from his pulpit and by his writings raised "the alarm cry of a watchman in Sion."

The direct originator of the movement was Philip Jacob Spencer, who combined the Lutheran emphasis on Biblical doctrine with the Reformed tendency to vigorous Christian life. Born at Rappoltsweiler, Alsace, and educated at the University of Tübingen, he was trained by a devout godmother, who used books of devotion like Arndt's True Christianity, accustomed to hear the sermons of a pastor who preached the Bible more than the Lutheran creeds, Spencer was early convinced of the necessity of a moral and religious reformation of the German Church. He studied theology, with a view to the Christian ministry, at Strassburg, where the professors at the time (and especially Sebastian Schmidt) were more inclined to practical Christianity than to theological disputations. He afterwards spent a year in Geneva, and was powerfully influenced by the strict moral life and rigid ecclesiastical discipline prevalent there, and also by the preaching and the piety of the Waldensian prophet, Antoine Leger, and the converted Jesuit preacher, Jean de Labadie. During a stay in Tübingen he read Grossgebauer's Alarm Cry, and in 1666 he entered upon his first pastoral charge at Frankfort-on-the-Main, profoundly impressed with a sense of the danger of the Christian life being sacrificed to zeal for rigid orthodoxy. Pietism, as a distinct movement in the German Church, was then originated by Spencer by means of a public lecture in his house (casa borralia), at which he repeated his sermons, expounded passages of the New Testament, and induced those present to join in conversa-

tion on religious questions that arose. They gave rise to the name "Pietists." In 1675 Spener published his Pia Desideria, or Earnest Desires for a Reform of the True Evangelical Church. In this publication he made six proposals as the best means of restoring the life of the Church: (1) the earnest and thorough study of the Bible in private meetings, ecclesiœs in ecclesiœ; (2) the Christian priesthood being universal, the laity should share in the spiritual government of the Church; (3) a knowledge of Christianity must be attended by the practice of it as its indispensable sign and supplement; (4) instead of merely didactic and often bitter, attacks on the heterodox and unbelievers, a sympathetic and kindly treatment of them; (5) a reorganization of the theological training of the universities, giving more prominence to the devotional life; and (6) a different style of preaching, namely, in the place of pleasing rhetoric, the implanting of Christianity in the inner or new man, the soul of which is faith, and its effects the fruits of life. This work produced a great impression throughout Germany, and although large numbers of the orthodox Lutherans and pastors were deeply offended by Spener's book, its complaints and its demands were both too well justified to admit of their being point-blank denied. A large number of pastors at once practically adopted Spener's proposals. In Paul Gerhardt the movement found a singer whose hymns are genuine folk poetry. In 1686 Spener accepted an appointment to the court-chaplaincy at Dresden, which opened to him a wider though more difficult sphere of labour. In Leipzig a society of young theologians was formed under his influence for the learned study and devotion of the Bible. Three of these Spener called his "collegia," one of whom was August Hermann Francke, subsequently the founder of the famous orphanage at Halle (1695), commenced courses of expository lectures on the Scriptures of a practical and devotional character, and in the German language, which were zealously frequented by both students and townsman.

The lectures aroused, however, the ill-will of the other theologians and pastors of Leipzig, and Francke and his friends left the city, and with the aid of Christian Thomasius and Spener founded the new university of Halle. The theological chairs in the new university were filled in complete conformity with Spener's proposals. The main difference between the new Pietistic school and the orthodox Lutherans arose from the conception of Christianity as chiefly consisting in a change of heart and consequent holiness of life, while the orthodox Lutherans of the time made it to consist mainly in correctness of doctrine.

Spener died in 1705; but the movement, guided by Francke, fertilized from Halle the whole of Middle and North Germany. Among its greatest achievements, and from the philanthropic institutions founded at Halle, were the organization of the Moravian Church in 1727 by Count von Zinzendorf, Spener's godson and a pupil in the Halle Orphanage, and the establishment of the great Protestant missions, Ziegenbalg and others being the pioneers of an enterprise which until this time Protestantism had strangely neglected.

Pietism, of course, had its weaknesses. The very earnestness with which Spener had insisted on the necessity of a new birth, and on a separation of Christians from the world, led to exaggeration and fanaticism among followers less distinguished than himself for wisdom and moderation. Many Pietists soon maintained that the new birth must always be preceded by agones of repentance, and that only a regenerated theologian could teach theology, while the whole school shunned all common worldly amusements, such as dancing, the theatre, and public games. There thus arose a new form of justification by works. Its ecclesiœs in ecclesiœ also weakened the power and meaning of church organization. Through these extravagancies a reaction movement arose. At the beginning of the 18th century, one of the most distinguished leaders of which was Loechler, superintendent at Dresden.

As a distinct movement Pietism had run its course before the middle of the 18th century; by its very individualism it had helped to prepare the way for another great movement, the Illumination (Aufklärung), which was now to lead the world into new paths. Yet Pietism could claim to have contributed largely to the revival of Biblical studies in Germany, and to have made religion once more an affair of the heart and the life, and not merely of the intellect. It likewise vindicated afresh the rights of the Christian laity in regard to their own beliefs and
PIETRO DELLA VIGNA—PIG

the work of the Church, against the assumptions and despotism of an arrogant clergy. "It was," says Rudolf Sohn, "the last great surge of the waves of the ecclesiastical movement begun by the Reformation; it was the completion and the final form of the Protestantism created by the Reformation. Then came a time when another intellectual power took possession of the minds of men."

Some writers on the history of Pietism—e.g. Hepp and Ritschl—have included under it nearly all religious tendencies amongst Protestants of the last three centuries in the direction of a more serious cultivation of personal piety than that prevalent in the various established churches. Ritschl, too, treats Pietism as a retrograde movement of Christian life towards Catholicism. Some historians also speak of a later or modern Pietism, characterizing thereby a party in the German Church which was probably at first influenced by some remnants of Spener's Pietism in Westphalia, on the Rhine, in Wurttemberg, and at Halle and Berlin. The party was chiefly distinguished by its opposition to an independent scientific study of theology, its principal theological leader being Hengstenberg, and its chief literary organ the Evangelische Kirchenzeitung. The party originated at the close of the wars with Napoleon I.

PIETRO DELLA VIGNA, or PIER DELLE VIGNE [PETRUS DE VINEAS OR DE VINEIS] (c. 1190-1249), chancellor and secretary to the emperor Frederick II., was born at Capua in humble circumstances. He studied law at Padua, and through his classical education, his ability to speak Latin and his poetic gifts, he gained the favour of Frederick II., who made him his secretary, and afterwards judex magnae curiae, councillor, governor of Apulia, prothonotary and chancellor. The emperor, "of whose heart he held the keys," as Dante says, sent him to Rome in 1232 and 1237 to negotiate with the pope, to Padua in 1239 to induce the citizens to accept imperial protection, to England in 1234-1235 to arrange a marriage between Frederick and Isabella, sister of King Henry III. He proved a skilful and trustworthy diplomat, and he persistently defended the emperor against his traducers and against the pope's menaces. But the Church of Lyons, which had been summoned by Pope Innocent IV., Pietro della Vigna entrusted the defence of his master to the celebrated jurist Taddeo of Sessa, who failed to prevent his condemnation. Frederick, whose suspicions had been awakened by the slanders of the envious, had him imprisoned and blinded without giving him a chance to rebut his accusers. Unable to bear his disgrace, he committed suicide in his prison at Pisa in 1249. The exact date, place and manner of his death are, however, subject to controversy, and Flaminio del Borgo states that it occurred in the church of S. Andrea, at Pisa, in 1256. The tragic fate of this man gave rise to many legends. The Guelph tradition accuses Pietro della Vigna, as well as the emperor and the court, of heresy; it was even stated, probably without any foundation, that they were the authors of the famous work, De tribus impostoribus, wherein Moses, Christ, and Mahomet are blasphemously accused.

Pietro della Vigna was a man of great culture; he encouraged science and the fine arts, and contributed much to the welfare of Italy by wise legislative reforms. He was the author of some delicate verse in the vernacular tongue, of which two canzoni and a sonnet are still extant. His letters, mostly written in the name of the emperor and published by Iselin (Epistolatarum

Hijri vii, 2 vols., Basel, 1740), contain much valuable information on the history and culture of the 13th century. A collection of the laws of Sicily, a Tractatus de pontestate imperiali, and another treatise, "On Consolation," in the style of Boethius, are also attributed to him.

See Hulard-Bréholles, Vie et correspondance de Pierre de la Vigne (Paris, 1864); Presta, Pier delle Vigne (Milan, 1880); Capasso and Ianelli, Pier delle Vigne (Cascia, 1882); also Frederick II.

PIG (a word of obscure origin, connected with the Low Ger. and Dut. word of the same meaning, bigge), a common name given to the domesticated swine of agricultural use. (For the zoology, see SWINE.)

British breeds of pigs are classified as black, white and red. In some places, notably Wales and Gloucester, a remnant of a spotted breed lingers; and a large proportion of common pigs, often parti-coloured, are mongrels. The white breeds are liable to sun-scald, and black pigs (like black men) are much better adapted than white to exposure in strong sunlight, conforming to the rule that animals in the tropics have black skins.

The Large Whites may have in the skin a few blue spots which grow white hair. The head is long, light in the jowl, and wide between the eyes, with long thin ears inclined slightly forward and fringed with long fine hair. The neck is long, but not coarse, the ribs are deep, the loin wide and level, the tail set high, and the legs straight and set well outside the carcass. The whole body, including the back of the neck, is covered with straight silky hair, which denotes quality and lean meat. Pigs of this breed are very prolific, and they may be grown to enormous weights—over 11 cwt. alive.

The Middle Whites are built on a smaller scale than the Large Whites. They are shorter in the heads and legs, and fuller at the jowl, thicker and more compact in the body. The sows are quite as prolific as those of the Large White breed, and, as their produce matures earlier, they are much in demand for breeding porkers.

The Small White pigs are beautifully proportioned. The head and legs are very short, and the body short, thick and wide; the jowl is heavy, the ears pricked, and the thin skin laden with long silky, wavy, but not curly, hair, whilst the tail is very fine. A deficiency of lean meat is a common characteristic of the breed, which is almost extinct.

The above three breeds were designated Yorkshire Whites, and are still so named at times. The Middle White, formed by crossing the large and the small breeds, is not so symmetrical as the parent stocks, and the type is not uniform.

The Lincolnshire Curly Coated or Boston pig is a local breed of great size and capacity for producing pork. It is very hardy and prolific, but somewhat coarse in the bone. It has an abundance of long curly hair, a short face and a straight nose, and the ears, not too long and heavy, fall over the face. It crosses well with the Large White, the Large Black and the Berkshire.

The Large Black breed, which vies with the Large White breed for size, and is probably its superior as a bacon pig, has only since 1900 received national show-yard recognition; but there is ample evidence that, with its characteristic whole black colour with a mealy hue, length, fine hair and top ear, the Large Black existed in the south of England for generations. It has been continuously and carefully bred in Cornwall, Devon, Essex and Suffolk, and from these centres it has rapidly spread all over the country. Large Blacks are exceedingly docile, and the ears, hanging well forward over the eyes, contribute materially to a quietness of habit which renders them peculiarly adapted to field grazing. On account of their hardihood and disposition to early maturity they have proved valuable for crossing purposes.

The Large Black Pig Society was incorporated in 1890.

The Berkshire is a black pig with a pinkish skin, and a little white on the nose, forehead, pasterns, and tip of the tail. It has a moderately short head with heavy jowl, a deep, compact carcase, and wide, low and well-developed hind-quarters, with heavy hams. The skin carries an abundance of fine hair. The Berkshire is an early-maturity breed which has been somewhat
PIG

inbred, and is not so hardy and prolific as most breeds. The boars cross well with common stock. It merits the most credit in raising the quality of Irish pigs. In America it is in the front rank for numbers and quality as a porker. That often grows to be a larger and finer animal than it is in England.

The Small Black or Black Suffolk was produced from the old Essex pig by crossing with the Neapolitan. It resembles the Small White, except that the skin is coal-black in colour, and the coat of hair is not usually profuse. The Small Black, moreover, is rather longer, and stands somewhat higher, whilst it yields more lean meat than the Small White. It matures early and is quick to fatten.

The Tamworth is one of the oldest breeds of pigs. It is hardy, active and prolific, and nearly related to the wild boar. The colour is red or chestnut, with at times darkish spots on the skin. The head, body and legs are long, and the ribs deep and flat. Originally a local breed in the districts around the Staffordshire town from which it takes its name, it is now extensively bred, and highly valued as a bacon pig. (W. F.; R. W.)

In America nearly all the breeds may be classified as lard-hogs. Bacon-pigs fed on Indian corn degenerate into lard-hogs, run down in size and become too small in the bone and less prolific by inbreeding.

The Poland-China, the most popular breed in the United States, is thus degenerating. It is a black pig like the Berkshire, but has shorter legs, a more pointed, straight nose, a more contracted body, and more white markings. It is a breed of mixed blood, and is believed to have originated from the “Big China” pig—a large white hog with sandy spots, taken to Ohio in 1816, and blended with Irish graziers in 1859, and with a breed known as Bayfields, as well as with Berkshires. In Iowa the Berkshire is a combined lard and bacon pig in high favour.

The Duroc Jersey or Duroc, of a red or cherry-red colour—not sandy or dark—is the most popular pig in Nebraska and equal to any other in Iowa. It is a large prolific lard-hog, easily making 300 lb in eight months. It has gained rapidly in popularity since the beginning of this century, and is spreading to other centres.

The Chester White, named from Chester county, Pennsylvania, is one of the four leading breeds of lard-hogs in America. It is of mixed origin and bears a strong family resemblance to the Lincolnshire curly-coated pig. The early English ancestors, the breed of which is not on record in America, were most probably of Lincoln origin. The sow is a prolific breeder and good mother, weighing when mature but not fat, 450 lb—the boar averaging 600 lb, and being raised to eight months of age. At the Young Men’s Institute, in a 120 days’ test, Chester Whites made an average gain of 1.36 lb and dressed 84.5 per cent. carcass, and they can gain fully 1 lb of live weight for 3 lb of grain consumed.

Management—The brood sow should be lengthy and of a prolific strain, known to milk well. She is moderately fed and put to a boar of her own age when large enough, i.e. seven to eight months old. She remains in a state of oestrus for about three days, and if not pregnant comes in heat again in three weeks. She is best in a sheltered spot, but if in the open she should have a sheltering hedge. To induce her to eat, √ has been found to be the most effectual. When not pregnant, the sow should be kept at pasture and allowed to feed on stubble and other material which may be found. When the sow is fed on grass she has a more tender and delicate flesh than when fed on hay. The piglet is weaned at four or five weeks of age, but the sow is allowed to suckle them, and consists of a covered compartment and outer court, each 10 ft. square. When the animals are fed outside the inner court is kept clean and dry, and there the pigs lie. The labouring man’s pig is his best, as the young pigs are fed on greens, scraps, and male flies, and the time of pasture and will be consumed in the autumn. One of the most important features of a good pig of this kind is to have a proper feed and good care from the time the sow is in with her piglet. The sow should be fed on good greens, and the young pigs on scraps, and the sow should be allowed to feed on the grass as much as possible. In conclusion, cheese dairies pigs are largely fed on sour whey thickened with mixed meal produced from any or all of the grains or pulses, the choice depending upon the market price. Fat may with advantage be cooked for very young pigs; but, with the exception of potatoes, which should never be given raw, roots and meals are best given uncooked. Meat mixed with pulped roots for a few hours improves in digestibility, and a sprinkling of salt is an improvement. Meat derived from leguminous seeds makes the flesh firm and improves the quality. Fattening pigs are fed three times a day and supplied with coal-ashes or a few handfuls of earth. Of the fattened weight of a pig 83 per cent. is butter’s carcass, and 91 per cent. of the increase from 100 to 200 lb is carcass. From 3 to 5 lb of meal consumed results in an increase of 1 lb of live weight in a pig, which is the most economical method in producing on farms. Concentrated and digestible foods give best results, a pig has a small stomach. Fjord’s Danish experiments show that fattening pigs 1 lb of rye or barley-meal is equivalent to 6 lb of skim milk or 12 lb of potatoes, and 1 lb of meal equivalent to 8 lb of potatoes or 4 lb of potatoes.

PIGALLE, JEAN BAPTISTE (1714-1785). French sculptor, was born in Paris on the 26th of January 1714. He was the seventh child of a carpenter. Although he failed to obtain the grand prix, after a severe struggle he entered the Academy and became one of the most popular sculptors of his day. His early work, such as “Child with Cage” (model at Sèvres) and “Mercury Fastening his Sandals” (Berlin, and lead cast in Louvre), is less common than that of his mature years, but his nude statue of Voltaire, dated 1776 (Institut), and his tombs of Comte d’Harcourt (c. 1764) (Notre Dame) and of Marshal Saxe, completed in 1777 (Lutheran church, Strassburg), are good specimens of French sculpture in the 18th century. He died on the 28th of August 1785.

See P. Tarbé, Vie et oeuvres de Pigalle (1859); Saund, Éloge de Pigalle; Mélanges de littérature.

PIGALLET-LEBRUN (Pigault de l’Epinoy), CHARLES ANTOINE GUILLAUME (1753-1835). French novelist, was born at Calais (he is said to have traced his pedigree on the mother’s side to Eustache de St Pierre) on the 8th of April 1755. His youth was stormy. He twice carried off young ladies of some position, and was in consequence twice imprisoned by lettre de cachet. The first, a Miss Crawford, the daughter of an English merchant whose office Pigault had entered, died almost immediately after her elopement; the second, Mlle de Salens, he married. He became a soldier in the Queen’s Guards, then a very unsuccessful actor, and a teacher of French. At the breaking out of the great war he re-entitled and fought at Valmy. He wrote more than twenty plays, and a large number of novels, the first of which appeared in 1787. In his old age he took to gravier work, and executed an abridgement of French history in eight volumes, besides some other work. His Œuvres complètes were published in twenty volumes between 1822 and 1824, but much of his work is subsequent to this collection. He died on the 24th of July 1835. The style of Pigault’s novels is insignificant, and their morality very far from severe. As almost the father of a kind of literature which later developed enormously, Pigault-Lebrun deserves a certain place in literary history. Among the most celebrated of his novels may be mentioned L’Entend du Carnaval (1792) and Angélique et Jeanne de la place Mambert (1799). His Citations (2 vols., 1803), a collection of quotations against Christianity, was forbidden and yet several times reprinted.

PIGEON (Fr. pigeon, Ital. piccione and pipione, Lat. pipio, literally a nestling-bird that pipes or cries out, a "piper"—the very name now in use among some pigeon-fanciers, though "squeaker" in the more usual term). The name pigeon, doubtless of Norman introduction as a polite term, seems to bear much the same relation to dove, the word of Anglo-Saxon origin, that mutton has to sheep, beef to ox, veal to calf, and pork to bacon; no sharp zoological distinction can be drawn (see Dove) between dove and pigeon, and the collective members of the group Columbae are by ornithologists ordinarily called pigeons. Perhaps the best-known species to which the latter name is exclusively given in common speech is the wild pigeon.

1 It may be observed that the "rock-pigeons" of Anglo-Indians are Sand-grouse (q.v.), and the "Cape pigeon" of sailors is a petrel (q.v.).
or passenger pigeon of North America, *Ectopistes migratorius*, which is still found in many parts of Canada and the United States, though now almost extinct and never appearing in the countless numbers that it did of old, when a flock seen by A. Wilson was estimated to consist of more than 2230 millions. The often-quoted descriptions given by him and J. J. Audubon of pigeon-haunts in the then “backwoods” of Kentucky, Ohio and Indiana need not here be reproduced. That of the latter was declared by C. Waterton to be a gross exaggeration; but the critic would certainly have changed his tone had he known that, some hundred and fifty years earlier, passenger-pigeons so swarmed and ravaged the colonists’ crops near Montreal that a bishop of his own church was constrained to exorcise them with holy water, as if they had been demons. The passenger-pigeon is about the size of a common turtle-dove, but with a long, wedge-shaped tail. The male is of a dark slate-colour above, and purplish-bay beneath, the sides of the neck being rufous, and the under tail coverts white-gold. The female was once in life colored above and dull white beneath, with only a slight trace of the brilliant neck-markings. (See plate illustration under Dove.)

Among the multitudinous forms of pigeons very few can here be noticed. A species which might possibly repay the trouble of domestication is the wonga-wonga or white-leshed pigeon of Australia, *Leucosarca picta*, a bird larger than the ring-dove, of a slaty-blue colour above and white beneath, streaked on the flanks with black. It is known to breed, though not very freely, in captivity, and is said to be excellent for the table. As regards flavour, the fruit-pigeons of the genus *Treron* (or *Vinoge* of some authors) and its allies surpass all birds. These inhabit tropical Africa, India, and especially the Malay Archipelago; but the probability of domesticating any of them is very remote. Hardly less esteemed are the pigeons of the genus *Ptilinopus* and its kindred forms, which have their headquarters in the Pacific Islands, though some occur far to the westward and also in Australia. There may be mentioned the strange Nicobar pigeon, *Caloenas* (see plate illustration under Dove), an inhabitant of the Indian Archipelago, not less remarkable for the long lustrous hackles with which its neck is clothed than for the structure of its gizzard, which has been described by Sir W. H. Flower (Proc. Zool. Soc., 1860, p. 430), though this peculiarity is matched or even surpassed by that of the same organ in the *Phevorhitha solia* of New Caledonia (Rev. de zoologie, 1862, p. 138) and in the *Carpophaga latrans* of Fiji. In this last the surface of the epithelial lining is beset by horn-like conical processes, adapted, it is believed, for crushing the very hard fruits of *Onocarpus vitis-* on which the bird feeds (Proc. Zool. Soc., 1873, p. 102). The modern giants of the group, consisting of twelve species of the genus *Columba* and known as crowned pigeons (see plate illustration under Dove), belong to New Guinea and the neighbouring islands, and are conspicuous by their large size, beautiful filmy fan-shaped crest, and the reticulated instead of scutellated covering of their “tarsi.”

A very distinct type of pigeon is that represented by *Didunculus strigirostris*, the “Manu-me” of Samoa, still believed by some to be the next of kin to the Dodo (q.v.), but really presenting only a superficial resemblance in the shape of its bill to that extinct form, from which it differs osteologically quite as much as do other pigeons (Phil. Trans., 1860, p. 349). It remains to be seen whether the Papuan genus *Odiphus*, of which several species are now known, may not belong rather to the Didunculidae than to the true Columbidae.

Pigeons are now regarded as belonging to the Charadriiform or plover-like birds (see Birds) and are placed in the sub-order

Columbae, near the sand-grouse (q.v.). They are divided into three families, *Dididae*, which includes the Dodo (q.v.) and *Solitaire*, the Columbidae, which includes the doves and pigeons, and the Didunculidae, of which the curious tooth-billed pigeon, of Samoa is the only example. The body is always compact, and the bill has a soft skin or cere covering the nostrils. The pigeons are chiefly vegetable feeders and have a hard gizzard, and all drink much water; they perch, and have a note of the nature of a “coo.” The nest is a rough platform or is in holes on the ground or in rocks. The eggs are two or three and white, and the young, which are helpless when hatched, are fed by a secretion from the crop of the parents. (A. N.)

**PIGEON-FLYING,** the sport of racing homing-pigeons bred and trained for the purpose. It is of very recent date, although the use of birds as a means of carrying messages (see Pigeon Post) is of great antiquity. Belgium may be considered as par excellence the home of the sport, the first birds flown there probably occurring in 1874. Among fossil pigeons described in 1878, with a match of 100 m., while in 1820 there was a race from Paris to Liége, and three years later the first race from London to Belgium. The sport is now a favourite one in Great Britain, the United States, France, and, to a less degree, in some other countries, although nowhere attaining the general popularity which it enjoys in Belgium, where nearly every village has its Société colomophile, millions of pigeons being sent over the French border to be raced back. The annual Belgian concours national, a race of about 500 m. from Toulouse to Brussels, was inaugurated in 1881, in which year the first regular races in Great Britain, from Exeter, Plymouth and Penzance to London, took place. The velocity attained at that time was about 1250 yds. per minute, but this was soon surpassed in the races of the London Columbian Society, one of the winners in which attained a speed of 1856 yds. per minute.

The sport was introduced into the United States about the year 1875, although regular racing did not begin until 1878. Since then it has gained widespread popularity, the American record for old birds at 300 m. being 1848 yds. per minute and for young birds (yearlings) 1665 yds., while the distance record is 1004 m. The American “blue ribbon” championships are held at 100, 200, 300, 400, 500 and 600 m. The speed of homing-pigeons depends very greatly upon the state of the atmosphere. In the race from Montargis to Brussels in 1876 in bright and clear weather, all the prize-winners made the distance of 270 m. within three and one-quarter hours, while in the same race in 1877, on a thick and stormy day, thirty hours passed before the first bird arrived.

**Training.**—The loft should be on a commanding site. It is best made in the shape of a large room, suitably subdivided, protected from vermin, and provided with drinking troughs, rock salt and crushed mortar for the bird’s use. It should be fitted with a sufficient number of nests about 2 ft. long, 20 in. in breadth and height. Arrangements should be made for allowing the pigeons to fly out daily for exercise; and they should be trained to re-enter the loft through bolting wires, which open inwards only, into a small chamber, to which an electric arrangement may be fitted so as to allow them to fly either from the loft or from this chamber. The food of birds in training consists of vetch, beans, maize, peas, broken rice and millet, in various proportions, according to the country, climate and season of the year, the daily allowance for each bird being calculated according to its age, and given in portions on rice in the husk and bread. They are called “squealers” for a week or two after birth, and then “squeakers” until about three months old. Each brood consists of two eggs, on which both parents sit in turn, the cock only for a few hours in the middle of the day. When the young are being brought up, only one of the parent birds is taken out at a time. One meal per day, given before the birds are let out in the morning, is sufficient. Training should commence in the latter part of the winter, and should extend about three months, and it consists in taking it out in a closed wicker basket and liberating or “tossing” it at gradually increasing distances from its loft, with several days interval of rest between the flights. The usual pre-
train the young homers alone, so that they may become independent of the older birds. When thoroughly trained they may be flown over long distances about once a week. The Belgian fanciers generally divide their birds into two classes, one for breeding and the other for racing, though the latter are allowed to breed within certain limits. Some fanciers always choose birds with chucks in the nest for long journeys, claiming that they return faster with this incentive. A seamless metal ring marked with the owner's name and number is put on each bird when it is young, and during its racing career the longer wing-feathers are stamped with the bird's records. At the start of a race the competing birds are tossed together by a starter who takes the time. Upon being released the homers ascend rapidly, in spirals at first, apparently driven by some familiar landmark on the horizon, it will fly straight and swiftly towards it. As the birds enter their home-lots the time is taken by the owner. A bird is not considered to have got "home" until it has actually passed through the door of its loft.

PIGEON POST. The use of homing pigeons to carry messages is as old as Solomon, and the ancient Greeks, to whom the art of training the birds came probably from the Persians, conveyed the names of Olympic victors to their various cities by this means. Before the electric telegraph this method of communication had a considerable vogue amongst stockbrokers and financiers. The Dutch government established a civil and military pigeon system in Java and Sumatra early in the 19th century, the birds being obtained from Bagdad. Details of the employment of pigeons during the siege of Paris in 1870-71 will be found in the article POST AND POSTAL SERVICE: France. This led to a revival in the training of pigeons for military purposes. Numerous private societies were established for keeping pigeons of this class in all important European countries; and, in time, various governments established systems of communication for military purposes by pigeon post. When the possibility of using the birds between military fortresses had been thoroughly tested attention was turned to their use for naval purposes, to send messages between coast stations and ships at sea. They are also found of great use by news agencies and private individuals. Governments have in several countries established lots of their own. Laws have been passed making the destruction of such pigeons a serious offence; premiums to stimulate efficiency have been offered to private societies, and rewards given for destruction of birds of prey. Pigeons have been used by newspapers to report yacht races, and some yachts have actually been fitted with lofts. It has also been found of great importance to establish registration of all birds. In order to hinder the efficiency of the systems of foreign countries, difficulties have been placed in the way of the importation of their birds for training, and in a few cases falcons have been specially trained to interrupt the service in war-time, the Germans having set the example by employing hawks against the Paris pigeons in 1870-71. No satisfactory method of protecting the weaker birds seems to have been evolved, though the Chinese formerly provided their pigeons with whistles and bells to scare away birds of prey.

In view of the development of wireless telegraphy the modern tendency is to consider fortress warfare as the only sphere in which homing pigeons can be expected to render really valuable services. Consequently, the British Admiralty has discontinued its pigeon service, which had attained a high standard of efficiency, and other powers will no doubt follow the example. Nevertheless, large numbers of birds are, and will presumably continue to be, kept at the great inland fortresses of France, Germany and Russia.

See L. de Puy de Podio, Die Briefe in der Kriegskunst (Leipzig, 1872); Brinckeiner, Anzucht, Pflege, und Dressur der Briefeilen (Limenau, 1891).

PIGEON-SHOOTING, a form of sport consisting of shooting at live pigeons released from traps. The number of traps, which are six-sided boxes, falling flat open at the release of a spring, is usually five; these are arranged 5 yds apart on the arc of a circle of which the shooter forms the centre. The distance (maximum) is 31 yds, handicapting being determined by shortening the distance. The five traps are each connected by wires with a case ("the puller"); a single string pulled by a man stationed at the side of the shooter works an arrangement of springs and cog-wheels in the "puller," and lets fall one of the traps; it is impossible to know beforehand which trap will be released. At a fixed distance from the centre of the traps is a boundary within which the birds hit must fall if they are to count to the shooter. This line varies in distance in the various clubs; the National Gun Club boundary being 65 yds., that of the Monaco Club being only 20 yds. The charge of shot allowed must not exceed 1½ oz. The best type of pigeon is the blue rock. From the start of the Hurstington Club at Fulham in 1867 pigeon-shooting was a favourite sport there; it was, however, stopped in 1906. The principal pigeon-shooting centre in England is now at the National Gun Club grounds at Hendon. The great international competitions and sweepstakes take place at Monaco. An artificial bird of clay, now more usually of a composition of pitch, is often substituted for the live pigeon. These clay birds are also sprung from traps. This sport originated in the United States, where, under the name of "trap-shooting," or inanimate bird shooting, it is extremely popular. At first the traps invented threw the birds with too great regularity of curve; now the traps throw the birds at different and unknown angles, and the skill required is great. In clay-bird shooting the traps usually number fifteen, and are out of sight of the shooter. The Inanimate Bird Shooting Association in England was started in 1893.

PIGMENTS (Lat. pigmentum, from pingere, to paint). It is convenient to distinguish between pigments and paints, the latter being prepared from the former by the addition of a vehicle or medium. Nor are pigments and dyes identical, although there are cases in which the same colouring matter which yields a dye or stain may give rise to a pigment. A pigment is, in fact, a substance which is insoluble in the vehicle with which it is mixed to make a paint, while a dye is soluble. Pigments exhibit various degrees of transparency and opacity, and ought to possess such qualities as these: ease in working, chemical indifference to each other and, generally, to the vehicles employed, also stability under exposure to light and air. As a rule, it is desirable that pigments should not be seriously affected in hue by the vehicle; at all events, whatever change does occur is found to be for the better. In the case of oil colours it should be remembered that a thorough drying of the paint is preferable to the formation of a surface-skin, and that a few pigments, notably white lead, possess properties conducing to this desirable result. It is scarcely necessary to add to these general observations concerning pigments that their artistic value depends primarily upon the nature and amount of the optical sensation which they are competent to produce. Although the number of available pigments is great, the number of chemical elements which enter into their composition is not large. Very many richly-coloured compounds cannot be employed because they lack the properties of insolubility, inertness and stability. Pigments are drawn from various sources. Some are natural, some artificial; some are inorganic, some organic, some are elements, some mixtures, some compounds. It is not unusual to arrange them into two groups, substantive and adjective. Amongst the members of the former group such a pigment as vermilion, where each particle is homogeneous, may be cited as an example. Amongst the adjective pigments rose-madder may be named, for each particle consists of a colourless base on which a colouring matter (alizarin) has been thrown. Most of the inorganic pigments, whether natural or artificial, belong to the substantive group; while there are many organic pigments, notably those of artificial origin, which are of adjective character. The following table presents a summary classification of pigments according to their source or origin:

<table>

A variety of processes are in use in order to fit natural coloured substances for employment as pigments. The first step is,
PIGMENTS

in many cases, to select, or "pick over," the raw material, rejecting whatever impurities may weaken or injure the characteristic hue of the product. It is occasionally necessary to treat the finely-ground substance with water by the method of elutriation or washing-over; the wash-waters will then deposit, on standing, various grades of the coloured body required. With rare exceptions native pigments need careful grinding, either by means of a muller on a slab or by edge rollers, or horizontal mill-stones, or special machines. The substance is usually ground in spirits of turpentine, or alcohol, or water; oil-paints are of course finally ground in a drying-oil, such as linseed oil or poppy oil; water-colours require gum-water, or gum-water and glycerin if they are to be "moist" paints. In the case of all pigments, whether mineral or organic, whether natural or artificial, it is of the highest importance to make sure that they are free from saline matters soluble in water. Such salts are removed by thorough washing with distilled water. A treatment of this kind is essential in the case of a large number of pigments formed by chemical reactions in the "wet way." Characteristic examples are furnished by Prussian blue, viridian and lake. Sometimes it is necessary to remove dangerous impurities by solvents other than water, such as carbon bisulphide, which is used to extract free sulphur from cadmium yellow. Mention may here be made of another kind of preparative treatment which is adopted with some pigments: they are subjected to the action of heat—moderate in some cases, strong in others. Thus, a few substances, such as ivory black and yellow ochre, which in ordinary circumstances contain much non-essential moisture, before they are ground in oil may with advantage be gently dried at a temperature not above that of boiling water. Again, there are pigments, such as Prussian brown, light red and burnt sienna, which owe their hues to a process of actual calcination, the first of these being thus made from Prussian blue, the second from yellow ochre, and the third from raw sienna. The pigments known as burnt canthar and burnt madder are prepared at a much lower temperature, and ought to be described as roasted rather than as burnt.

The substitution of one pigment for another is rarely practised, but it is not so unusual to find that a costly substance has received an admixture of something cheaper, and that an inferior grade of a genuine pigment has had its hue exalted or enhanced by some unlawful or dangerous addition. In fact, these two kinds of sophistication are often associated. Thus vermillion is adulterated with red lead, with red antimony sulphide, or with baryta white and lead sulphate, and then the hue of the mixture is restored to the proper pitch by the introduction of the powerful but fugitive colouring matter essence. Amongst other adulterations which may be named here are the addition of chrome-yellow (lead chromate) to yellow ochre, of green ultramarine to terre verte, and of indigo to ivory black; this last mixture being a substitute for vine-black, the natural blue-black. The detection of the above-named sophistications is by no means difficult even in the hands of persons unacquainted with chemical manipulation, but it needs a trained analyst when quantitative results are required. If we are dealing with an oil-colour, the first step is to remove the oil by means of a solvent, such, for example, as ether. The residue is then allowed to dry, and the dry powder submitted to the appropriate physical and chemical tests. Thus a suspected vermillion, having been freed from oil, is heated in a small hard glass bulb-tube: it should prove practically volatile, leaving a mere trace of residue. In this particular case the presence of a red hue in the ether-extract affords evidence of adulteration with an organic colouring matter, such as eosin. Then, again, we may detect the presence in yellow ochre of lead chromate by pouring a little sulphanuret hydrogen water and dilute hydrochloric acid upon one portion of the dry pigment, and boiling another portion with dilute sulphuric acid and some alcohol: in the former experiment blackening will occur, in the latter the liquid part of the mixture will acquire a greenish tint. So also green ultramarine may be recognized in adulterated terre verte by the addition of dilute hydrochloric acid, which destroys the colour of the adulterant and causes an abundant evolution of the evil-smelling sulpher- etted hydrogen. Moreover, nothing is easier than the recognition of indigo in vine or charcoal-black, for the dry powder, heated in a glass tube, gives off purple vapours of indigo, which condense in the cooler part of the tube into a blackish sublimate.

A word must be said here as to the adulteration of white lead, and the examination of this most important pigment. The best variety of white lead or flake white contains two molecules of lead carbonate to one of lead hydrate, and is wholly soluble in dilute nitric acid, while barium sulphate, its most frequent adulterant, is wholly insoluble. China-clay and lead sulphate will also remain undissolved; but whitening or chalk cannot be detected in this way—indeed, the thorough examination of white lead, not only for sofistications but also for correspondence with the best type in composition, cannot be carried out save by a skilled chemist.

Pigments may be classified on two systems: (1) based on the chemical composition; (2) based on the colour. On the first system pigments fall into nine groups, seven of which are fairly well defined, but the eighth and ninth have a somewhat miscellaneous character. The groups of elements, oxides, sulphides, hydrates, carbonates and silicates present this characteristic, namely, that each member of any one group is without action upon the other members of the group; any two or more may therefore be mixed together without fear of mutual injury. The same statement may be made with reference to the various inorganic salts of Group VIII., and to the organic compounds of Group IX., although in this large final group there are two pigments containing copper (verdigris and emerald green) which must be regarded with suspicion. The inertness of the members of the same group towards each other may be explained in the majority of cases by the oxide base of the pigment not acting upon an oxide, nor does a sulphide affect a sulphide, because all the pigment oxides have taken up their full complement of oxygen, and can neither give nor lose this element to similar oxides; so also with sulphur in the sulphides. A few details regarding the several members of the nine groups are now offered:

**Group I. Elements.**—All the black pigments in ordinary use—ivory black, lamp black, charcoal black, Indian ink, and graphite, less correctly termed black-lead and plumbo—consist of or contain carbon, an element not liable to change. The metallic pigments, gold, silver, aluminium and platinum, belong here; of these, silver is least easily susceptible of change, tarnishing by combination with sulphur.

**Group II. Oxides.**—The oxides have generally been formed at a high temperature and are not easily amenable to physical or chemical change; they are, moreover, not liable to affect other pigments, being practically inert, red lead only being an exception. The oxides include zinc white, green chromium oxide, burnt umber (a mixture of iron and manganese oxide), cobalt green (CoO3NaO), cobalt blue (CoO3Na2O), copper oxide (CoO), copper blue (CuO), copper yellow (CuO), copper green (CuO), vermillion red, light red, Indian red and burnt sienna (all chiefly composed of ferric oxide), and red lead (PbO2).

**Group III. Sulphides.**—Some of the members of this group are liable to contain traces of sulphur, and some may give up this element to the metallic bases of other pigments. Thus cadmium yellow blackens emerald green, producing copper sulphide. Another pigment of this group, vermilion, is prone to a molecular change when heated, and the red fume passes below the black incrustation. This change, frequent in water-colour drawings, is scarcely observable in works painted in oil. The sulphides comprise cadmium yellow (CdS), king's yellow (As2S3), realgar (As2S3), antimony red (Sb2S3) and verdigris (Cu2S). In the last group referred to the various kinds of ultramarine, blue, green, red, violet and native, for in all of them a part of the sulphur present occurs in the form of a sulphide. It may be stated that the sulphides of arsenic and antimony are just as liable to be dangerous and changeable pigments not suited for artistic painting.

**Group IV. Hydrates or Hydroxides.**—Several native earths belong here, notably yellow ochre, raw umber, raw sienna and Cappagh brown. These substances owe their colours mainly to hydrates and oxides of iron and of manganese, but the presence of a colourless body such as white clay or barium sulphate is usual with the paler pigments. A false yellow ochre from Cyprus is really a basic ferric sulphate, and does not properly belong to this
PIGMENTS

599

group. Besides the yellow and brown pigments, there is a magni-
cent deep green pigment in this group, known as emerald oxide of
cadmium or viridian. The blue copper preparation which goes
under the name of bleu janière and mountain blue, a very unstable
pigment, is made by melting the element in a copper cup; it has no
meanings. It should be stated that all the earthy or native hydrates
belonging to this group contain water in two states, namely, hygroscopic
or loosely-held and constitutional. Before grinding them in oil,
the reduction of the hygroscopic moisture by means of a
current of dry air or a gentle warmth often improves the hue
and working quality of these pigments.

Group V. Carbonates.—There is but one really important
membrane, that of bauxite, a typical vaterite and the old and typical
lead (2 PbCO₃, PbH₂O). Like green verditer (2 Cu₂O, CuH₂O),
and blue verditer (Cu₂O, CuH₂O), it is a basic carbonate. Purified
chalk or whitening (CaCO₃) belongs here also.

Group VI. Terre Verte.—There is a natural green
ochre containing a silicate of iron, potassium and magnesium,
and one silicate, smalt, an artificial glass containing a silicate of
coaltar and potassium, constitute this small group. However,
some of the ochreous earths contain silicates of iron, manganese
and aluminium, as well as hydrates of the two former metals, and
so have some claim to be ranked with the silicates.

Group VII. Chromates.—These salts are rich in oxygen.
When in contact with some of the more alterable organic pigments
belonging to Group IX, the chromates may lose oxygen, acquiring
a somewhat greenish or greyish hue, owing to the formation of
the lower or green oxide of chromium. The chromates cannot be
trusted. The yellow, chrome oxide, the red, chromic oxide, and
the violet, cobaltinitrite, are represented by the general formula
M₂CrO₄; chrome red is basic, and is Pb₂CrO₄.

Group VIII. Various Inorganic Salts.—This group is intended
to contain all the inorganic pigments, these being solitary,
examples of various classes of salts. There is one cobalt-
nitrite, aureolin (K₂Co(NO₃)₂, associated with one or more
molecules of water), called sometimes cobalt yellow; one antimonite,
that of lead, produces the yellow, lead antimonite, or bismuth yellow,
known as tungsten green; a metaphosphate of manganese, which
goes under the name of Nürnberg or manganese violet; and several
mixed cobalt compounds containing arsenates and phosphates of
that metal, as well as lead, and cobalt arsenate, known as verdigris.
Two sulphates also belong here, namely, baryta white (BaSO₄)
and lead sulphate (PbSO₄); also Schweinfurt green, a basic copper
arsenite. It is obvious that the members of so miscellaneous a
group, among so changing pigments, are liable to the greatest
fluctuation. But it may be stated that the two sulphates, the tansstate
and the cobalt compounds are practically inert and unalterable, while
the copper arsenite and the lead antimonite are sensitive to the action
of sulphur and of sulphides. The cobaltinitrite, aureolin, cannot
be safely mixed with some of the organic pigments belonging
to the next and last group.

Group IX. Organic Compounds.—Most of the members of this
large and important group of pigments owe their characteristic
properties to the presence of the element carbon, by means of
which is (x) common, proneness to oxidation and consequent deterioration
in the presence of light, moisture and air. Such oxidation is accelerated
by the action of highly oxidized pigments belonging to other
groups. The most familiar example of this action is that of Groups
of VIII., this action being particularly marked in the case
of the yellow lakes, the cochineal lakes and indigo. There are two
pigments consisting of copper salts in this group. They are verdigris
—or the blue, and the green, and the green varieties betag basic copper
acetates—and the pigment known in England as emerald-green,
which is a basic cupric acetate-arsenite. These copper pigments
present the usual sensitiveness to the attack of sulphur which dis-
istinguishes compounds of this metal, and cannot therefore be
mixed with the members of Group III., and more particularly with
the cadmium colours. About nine members of Group IX. may be
regarded as substantive pigments. These include Indian yellow
(土耳其黄 or Indian yellow, (H₂COSi(OH)₃, Si₂(OH)₃)),
bark red (木乃亚 or meng, (H₂COSi(OH)₃),
indigo. Prussian blue, bitumen or asphalt, biste, sepia, and the
bituminous variety of Vandyck brown. The adjective
includes a great variety of lakes where different kinds of colouring
matter, whether metallic halides or the base—generally of colourless
aluminium hydrate, aluminium phosphate, stannic hydrate, stannic oxide, bismuth or lime—
and the small quantities. The colouring
matters used are both natural and artificial. Amongst
the former may be named Indian lake, from the resinous exudation
produced in certain trees by the attacks of Coccus lacca; carmine,
cribri, also from this source, and various lake, from the
coaltar insect, Coccus cacti; rose-madder and the madder
lakes, from the alizarin and allied bodies derived from the root
of the ordinary madder plant Rubia tinctorum; and yellow lakes, from
quebracho or the bark of Lapacho (Lapacho tinctorum), and Prunus
berries (species of Rhamns or Buckthorn). The lakes derived
from bakaln root, archil, Brazil wood, and red sanders wood are
of very small interest and value. The same judgment may be
pronounced upon the larger number of artificial lakes, which owes
their colours to coaltar derivatives, with the singular exception
of the important class of pigments obtained from artificial alizarin,
and from its congeners and derivatives. Of these, alizarin (紫)
its, in its purest state and associated with alumina and a little
lime, yields those pigments which possess a pink or rosy hue. When
mixed with its isomeric anthrapurpurin and flavopurpurin, and
present, the red hue is more pronounced, and may even tend
towards a golden colour, or, when some copper or iron or manganese
is introduced, may become decidedly brown. Many of the alizarin
compounds yield most of the following species of alizarin from
these associations of the sulphonic acids of alizarin. These lakes present a wide range
of hues. Another derivative of alizarin, known as B-tro-nitro-alizarin,
yields a rich orange lake, to which such names as pure orange,
orange madder and marigold have been applied.

Stability.—Some notion of the relative stability of pigments
will have been derived from the remarks already made under
Classification.” But as permanence of of no less importance
than chromatic quality in the case of pigments used in the fine
art of painting, to which the present article is mainly devoted,
and further particulars concerning certain selected [,] Venetian red,
Indian red, red ochre, and the red lakes derived from madder
or alizarin. Vermilion is stable in oils, but as water-colour
paint is prone to change, under exposure to strong light, into
the black modification of mercuric sulphide. The iron-reds
named above, whether natural or artificial, are quite permanent,
but so much cannot be said of the various madder-paints. They
are of far greater stability under exposure to light than any other
red organic pigments, and are absolutely necessary to the artist.
It must be noted that those madder and alizarin lakes which
contain an element of yellow and brown are less stable than
those of a crimson hue. Five green pigments may be recom-
ended, namely, viridian, or the emerald oxide of chromium,
the ordinary green oxide, cobalt green, green ultramarine, and
terre verte. Except for minor decorative work, where permanence
is of secondary moment, one is obliged to exclude from the
palette emerald green, green verditer, verdigris, sap-green,
and the numerous preparations which owe their colour to mixtures
of Prussian blue and chrome yellow, and are sold under the
name of green vermilion, chrome green, Brunswick green, and so on.
All these pigments usually contain much barium sulphate.
Similarly, amongst blue pigments, ultramarine, cobalt blue
and coeruleum may be retained, while small, indigo and all
copper blues should be rejected. Prussian blue, or the mixture of this pigment with a white base which is usually called Antwerp blue, is scarcely be spared, but care should be taken to avoid a sample containing no potassium compounds. Coeruleum, which may be described as cobalt stannate presents the peculiarity of appearing a greenish blue in artificial light, not a purplish blue like that of ordinary cobalt blue. Cobalt violet is a sound pigment, while manganese metaphosphate or Nürnberg violet is said not to be safe in oil. Mars violet, an artificially prepared ferric oxide, is dull in hue but permanent. Passing on to brown pigments, it is matter for regret that there are no permanent colours possessing the artistic capacities of asphalt, madder brown, and the old bituminous Vandyke brown. Cappagh brown, burnt sienna, and raw and burnt umber may be employed safely. Little need be said as to the selection of black pigments, for all are permanent. The soot from burning acetylene, which has recently been introduced, forms a black pigment of remarkable intensity.

Uses.—Hitherto pigments have been considered chiefly in relation to the requirements of the painter of pictures. In many merely decorative arts, such as the manufacture of wall-papers and the painting of woodwork and of iron, the pigments available are in one direction, that of cost, more restricted, but, on the other hand, the artist has access to many alterable and commonly employed. In paints intended for the protection of iron-work, the nature of the pigment introduced is a matter of great moment, for red lead, zinc white and white lead are found to exert a strong protective influence, which is not observed in the case of the vast majority of pigments. There are a number of other uses besides those just named for which special pigments, or, more precisely, special paints, are employed. Amongst such preparations may be named luminous paints, anti-fouling paints, metallic paints, damp-proof paints, and asphalt and other fire-proof paints.

Church, Chemistry of Paints and Painting (London, 1901); G. H. Hurst, Painters’ Colours, Oils and Varnishes (London, 1901); S. Mierinski, Handburch der Pfarben-Fabrikation (Vienna, 1868); Riffault (and others), Fabricants de couleurs (Paris, 1884).

PIGOT, GEORGE, BARON (1719-1777), English governor of Madras, was born on the 4th of March 1719 and entered the service of the East India Company in 1736; after nineteen years, he became governor and commander-in-chief in 1755, and occupied Pondicherry on behalf of the company, he resigned his office in November 1763 and returned to England, being made a baronet in 1764. In the following year he obtained a seat in parliament, and this he retained until his death; in 1766 he was created an Irish peer as Baron Pigot. Returning to India in 1773 to occupy his former position at Madras, Pigot was at once involved in a fierce quarrel with the majority of his council, which arose out of the proposed restoration of the rajah of Tanjore. The governor was arrested by order of his opponents, and was still a prisoner when he died on the 11th of May 1777. Meanwhile the conduct of Pigot was censured by the court of directors in England and the order for his restoration was followed immediately by another for his recall. This happened about a month after his death, but before the news had reached England. In 1779 the matter was discussed in parliament, and four of those who were responsible for his arrest were tried and fined £1000 each. Pigot, who left several illegitimate children, was never married, and his barony became extinct.

Two of the governor’s brothers were men of reputation. SIR ROBERT PIGOT (1720-1796), who succeeded to the baronetcy, commanded his regiment (the 38th) at the battles of Lexington and Bunker Hill during the War of American Independence. He became a lieutenant-general in 1782. The other brother, HUGH PIGOT (c. 1721-1792), was a sailor. After some years of service he became an admiral and commander-in-chief in the West Indies in 1782. One of his sons was General Sir Henry Pigot (1758-1840), and another was Hugh Pigot (1769-1797), a captain in the navy, who was murdered during a mutiny in September 1797 while in command of the “Hermione.”

PIG-STICKING, or Hog-Hunting, the chase of the wild boar, as a sport, on horseback with the spear. The chase on foot was common among ancient peoples, and in central Europe has lasted to the present day, although, on account of the introduction of fire-arms, the spear has gradually become an auxiliary weapon, used to give the coup de grâce to a wounded animal. The modern sport is the direct descendant of bear-spearimg which was popular in Bengal until the beginning of the 19th century, when the bears had become so scarce that wild pigs were substituted as the quarry. The weapon used by the Bengalese was a short, heavy, broad-bladed javelin. British officers introduced the spear or lance and this has become the method by which pigs are killed. The season for hunting in northern India, the present headquarters of the sport, is from February to July. The best horses should be quick and not too big. Two kinds of weapon are used. The long, or underhand, spear, weighing from two to three pounds, has a light, tough bamboo shaft, from seven to eight feet long, armed with a small steel head of varying shape. This spear is held in the hand about two-thirds the distance from the point, with the knuckles turned down and the thumb along the shaft. The short, or jobbing, spear is from six to seven and a half feet long, and somewhat heavier than the longer weapon. It is grasped near the butt, with the thumb up. Although easier to handle in the jungle, it permits the nearer approach of the boar, and is therefore more dangerous to man and mount.

Having arrived at the bush-grown or marshland haunt of the pigs, the quarry is “reared,” i.e. chased out of its cover, by a long line of beaters, usually under the command of a mounted shikari. Sometimes dogs and guns loaded with small shot are used to induce an animal to break cover. The mounted sportmen, placed on the edge of the cover, attack the pig as soon as it appears; the majority of them carry a spear of “first spears,” or “spear of honour,” i.e. the thrust that first draws blood, being much coveted. As a startled or angry wild boar is a fast runner and a desperate fighter the pig-sticker must possess a good eye, a steady hand, a firm seat, a cool head and a courageous heart. For these reasons the military authorities encourage the sport, which is for the most part carried on by the tent clubs of the larger Indian stations.

PIKE ZEBULON MONTGOMERY (1779-1813), American explorer and soldier, was born in Lambert (now a part of Trenton), New Jersey, on the 5th of January 1779, son of Zebulon Pike (1731-1834), an officer in the American army. He entered his father’s company as a cadet about 1794, and became an ensign (or second lieutenant) in 1799 and first lieutenant in the same year. On the 9th of August 1805 he started with twenty men from St Louis to explore the head-waters of the Mississippi. At Prairie du Chien he met some Chippewa chiefs and induced them to expel the whisky-traders among them and to make peace with the Sioux; at the Falls of St Anthony (Sept. 23) he bought a tract 9 m. square at the mouth of the St Croix for a fort; and at Little Falls (in the middle of October) he built a stockade, where he left seven men. He reached Leech Lake (“Lake La Sang Sue”), which he called “the main source of the Mississippi,” on the 1st of February 1806; went 30 m. farther to Cass Lake (“Red Cedar”); and, after working against British influences among the Indians, turned back, and went down the Mississippi from Dean Creek to St Louis, arriving on the 30th of April. In 1806 he was
ordered to restore to their homes 50 Osages, redeemed by the
United States government from Potawatami, and to explore
the country. He started on the 15th of July; and went north
along the Missouri and the Osage into the present state of
Kansas and probably to the Republican river in the south of
the present Nebraska, where on the 29th of September he held a
grand council of the Pawnees. Then (early in October), turning
nearly south, he marched to the Arkansas river, which he reached
on the 14th of October, and up which (after the 28th with only
16 men) he went to the Royal Gorge (Dec. 7), having first
seen the mountain called in his honour Pike's Peak on the
23rd of November; and then went north-west, probably up Oil
Creek from Canon City. In searching for the Red river he came
to the South Platte, marched through South Park, left it by Trout
Creek pass, struck over to the Arkansas, which he thought was
the Red River for which he was searching; and, going south and
south-west, came to the Rio Grande del Norte (about where
Aimosa, Conejos county, Colorado, is now) on the 30th of
January 1807. There on the 26th of February he and a small
number of his men were taken prisoners by Spanish authorities,
who sent him first to Santa Fé, then to Chihuahua to General
Salcedo, and by a roundabout way to the American frontier,
where he was released on the 1st of July 1807. He was promoted
captain (August 1806), major (May 1808), lieutenant-colonel
(Dec. 1809) and colonel (July 1812). In 1808 he tried in vain to
get an appropriation from Congress for himself and his men. He
was military agent in New Orleans in 1809-1810, was deputy
quartermaster-general in April-July 1812, and was in active
service in the War of 1812 as adjutant and inspectorgeneral in
the campaign against York (now Toronto), Canada, and in the
attack on York on the 27th of April 1813 was in immediate
command of the troops in action and was killed by a piece of
rock which fell on him when the British garrison in its retreat
set fire to the magazine.

His Account of an Expedition to the Sources of the Mississippi and
through the Western Ports of Louisiana ... and a Tour through
the Interior Ports of New Spain was published at Philadelphia
in 1810; was reprinted and rearranged in London in 1811; and
was published in a French version in Paris in 1812, and a Dutch
version at Amsterdam in 1812-1813. The standard edition with memoir
and notes by Elliot Coues was published in three volumes in
New York in 1895. Some of Pike's papers taken from him in Mexico
are now in the Mexican archives (Seccion de Asuntos Inter-
nacionales raza 1817-1821), and the more important were pub-
lished by H. E. Bolton in the American Historical Review,
(1907-1908), xili. 798-827. See the sketch by Henry Whiting in

PIKE, fresh-water fishes generally distributed over the rivers
and lakes of Europe, northern Asia, and North America, and
forming a small family (Esocidae) of soft-rayed fishes. They
are readily recognized by their elongate compressed body covered
by a single stroke of the tail, they dash upon their prey or dart
out of reach of danger. In the Old World one species only is
known (Esox lucius), which prefers lakes and sluggish reaches of
rivers to strong currents or agitated waters. Its eastward
range in northern Asia is not known; it extends into Lapland
in the north and into central Italy and the vicinity of Constanti-
nople in the south, but is absent in the Iberian Peninsula. The
European species occurs also in North America, and is common
in the eastern United States southwards to northern Ohio. But
North America is tenanted by other species of pike besides, of
which the largest is the muskelunge or maskinonge of the Great
Lakes (Esox nubilus); it commonly attains to the large size which
is exceptionally recorded of Esox lucius. The other American
pike are of smaller size, and generally named "pickerel"; but
opinions as to the distinction of the species differ widely among
American ichthyologists. The European pike, like its brethren,
is the most voracious of fresh-water fishes; it probably exceeds
the shark, to which it has been compared by many writers, in
the relative quantity of food it consumes. Large specimens
will seize rats or water-voles, and are said to attack even foxes
and small dogs. Individuals of from 40 lb. to 50 lb. are not scarce,
but captures of much larger ones are on record. Pike are wholesome food, and much esteemed in inland coun-
tries—the smaller (of 20 to 24 in. in length) being preferred to
the larger individuals. They are prolific, and not easily exter-
minated in a water in which they have been once allowed to
spawn. According to season and climate they spawn in April
or May, and sometimes as early as February.

PIKE, a word which, with its collateral forms "pick" and
"peak," has as its basic meaning that of anything pointed or
tapering to a point. The ultimate etymology is much disputed,
and the interrelation of the Collins is very confused. In
Old English there are two forms (pic, one with a long and the
other with a short vowel, which give "pike" and "pick"
the latter is the original) and the variant "peak," first with reference to the peaked rocks in
the English Channel. In Romanic languages we find Fr. pic, Span. pico, Ital. picco, to pierce, &c. There are also
similar words in Welsh, Cornish and Breton. The Scandinavian
forms, e.g. Swed. and Nor. pikk, are probably taken from English.
While some authorities take the Celtic as the original, others
look to Latin for the source. Here the woodpecker, picus, is
referred to, or more probably the root seen in spica, ear of corn,
and spina, prick (English spike, spine). The current differen-
tiation in meanings attached to pike, pick and peak are more or
less clearly marked, though in dialects they may vary. (1) Pike:
Apart from the use as the name of the fish (see above),
probably a shortened form of pike-fish, from its sharp, pointed
beak, the common uses of the word are for a long hafted weapon
with sharply pointed head of iron or steel, the common weapon
of the foot-soldier till the introduction of the bayonet (see SPEAR
and BATON), and for a hill with a mounted battery, a term
appearing chiefly in the names of such hills in Cumberland, Westmorland
and North West Lancashire. It may be noticed that the
proverbial expression "plain as a pike-staff" appears originally
as "plain as a pack-staff," the flat plain sided staff on which a
pedlar carried and rested his pack. The use of "pike" for a
highway, a toll-gate, &c., is merely short for "turnpike." (2)
Pick: As a substantive this form is chiefly used of the common
tool of the navvy and the miner, consisting of a curved double-
ended head set at right angles to the handle, one end being
covered with a chisel edge, the other pointed, and used for
loosening and breaking hard masses of earth, coal, &c. (see
TOOLS). The other name for this tool, "pickaxe," is a corruption
of the earlier pikbas, Fr. picais, M. Lat. picium, formed
from Fr. pic, the termination being adapted to the familiar
English "axe." The sense-development of the verb to 'pick'
is not very clear; but the following meanings give the probable
line: to dig into anything like a bird with its beak, in order to
eXtract or remove something, to gather, pluck, hence to select,
choose. (3) Peak: The chief uses are for the front of a cap
or hat projecting sharply over the eyes, for the part of a ship's

European Pike (Esox lucius).
PIKE-PERCH—Pilate

hold where it narrows towards the bows, the fore-peak, or towards the stern, the after-peak, for the top corner of a sail extended by a gaff, or for the projecting end of the gaff itself, and for a pointed or conical top of a hill or mountain. The name of the high table-land district in Derbyshire is not to be connected with this word, but probably retains the name of an old English demon, *Pec* (see Peak, The).

**PIKE-PERCH** (*Lucioperca*), fresh-water fishes closely allied to the perch, but with strong canine teeth standing between the smaller teeth of the jaws and palate. They resemble the pike in their elongate body and head, and they are also most dangerous enemies to other fresh-water fishes, though they compensate for their destructiveness by the excellent flavour of their flesh. In Europe two species occur, the more celebrated being the "Zander" of North Germany or "Schiel" of the Danube (*Lucioperca sandra*); strange to say, it is absent in the system of the Rhine. It prefers the quiet waters of large rivers and clear deep lakes, in which it reaches a weight of 25 lb or 30 lb. The second (*Lucioperca wolgensis*) is limited to rivers in southern Russia and Hungary. In North America several pike-perches have been described, but in the most recent works only two are distinguished, viz. *Lucioperca americana*, which grows to a weight of 20 lb, and the much smaller *Lucioperca canadenesis*; both are abundant in the Canadian lakes and upper Mississippi, and the latter also in the Ohio.

**PIKE’S PEAK**, a famous peak of the Rampart range of the Rocky Mountains in El Paso county, Colorado, U.S.A., about 6 m. W. of Colorado Springs. Though surpassed in altitude (14,708 ft.) by many summits in the state, no other is so well known. The commanding appearance of the peak is very fine. To the south are Cameron Cone (10,685 ft.), Mt. Sachett, Mt Bald (15,974), Mt Rosa (11,427), and Mt Cheyenne (9497). From the summit the magnificent Sangre de Cristo range is in the foreground, while on a clear day not only its southermost summit, Blanca Peak (14,390 ft.) is visible, but also the Spanish Peaks (15,708 and 13,623 ft.) 100 m. to the south, and Long’s Peak 100 m. to the north, and between them Mt Lincoln, Gray’s Peak and other giants. At the base of the mountain are Manitou and Colorado Springs, whence tourists can make the ascent of the peak (in summer and relatively simple) on horseback or by cog-railway, 8 75 m. long (opened in 1891), which makes a total ascent of 8100 ft. (maximum gradient 1 in 4) to the summit. In 1905 a powerful searchlight was erected on the summit.

Pike’s Peak was discovered in November 1866 by Lieut. Zebulon M. Pike. He attempted to scale it, but took the wrong path and found himself at the summit of Cheyenne Mountain. He pronounced the mountain unclimbable. In 1819 it was successfully climbed by the exploring party of Major S. H. Long.

**PILASTER** (Fr. *pilastre*, med. Lat. *pilastrum*, from *pila*, a pillar), in architecture, an engaged pier projecting slightly from the wall, and employed to divide up and decorate a wall surface or to serve as a support to a column. One of the earliest examples of pilasters occurs in the propylaeum at Poseidonium in Asia Minor, where it tapers towards the top. Pilasters have bases and capitals and are frequently fluted like columns. The Romans seem to have preferred semi-detached columns, but for their amphitheatres sometimes pilasters are employed, as in the upper story of the Colosseum. In the revival of Classic architecture, and especially in Italy, architects seem to have considered that no building was complete without a network of pilasters on every storey, and France and England followed their example; and not only externally but inside the great cathedrals and churches the pilaster is adopted as the simplest and best way of dividing the bays.

**PILATE, PONTIUS**, the Roman governor of Judea under whom Jesus Christ suffered crucifixion. Of equestrian rank, his name Pontius suggests a Samnite origin, and his cognomen in the gospels, *Pilatus* (if derived from the *pilus* or cap of liberty), descent from a freedman. In any case he came in A.D. 26 from the household of Tiberius, through the influence of Sejanus, to be procurator over part of the imperial province of Syria, viz. Judaea, Samaria and Idumea. He ruled ten years, quarrelled almost continuously with the Jews—whom Sejanus, diverging from the Caesar tradition, is said to have disliked—and in A.D. 36 was recalled. Before he arrived Tiberius died, and Pilate disappears from history. Eusebius relates (*Hist. eccl.* ii. 7)—but three centuries later and on the authority of earlier writers unnamed—that he was exiled to Gaul and committed suicide at Vienne.

Pilate kept the Roman peace in Palestine but with little understanding of the people. Sometimes he had to yield; as when he had sent the standards, by night, into the Holy City, and was besieged for five days by suppliants who had rushed to Caesarea (*Jos. Ant.* 31; B. J. ii. x. 2, 3); and again when he hung up inscribed shields in Jerusalem, and was ordered by Tiberius to remove them to the other city (*Phil. ad Gaum.* 38). Sometimes he struck much more promptly; as when the mob protested against his using the temple treasure to build an aqueduct for Jerusalem, and he disguised his soldiers to disperse them with clubs (*Jos. Ant.* xvii. 3, 2); or when he "mingled the blood" of some unknown Galileans "with their sacrifices" (*Luke* xiii. 1); or slew the Samaritans who came to Mt Gerizim to dig up sacred vessels hidden by Moses there (*Jos. Ant.* xviii. 4, 1)—an incident which led to his recall. Philo, who tells how any suggestion of appeal by the Jews to Tiberius enraged him, sums up their view of Pilate in Agrippa’s words, as a man "inflexible, merciless, obstinate."

A more discriminating light is thrown upon him by the New Testament narratives of the trial of Jesus. They illustrate the right of review or *reconsciito* which the Romans retained, at least in capital causes; the charge brought in this case of acting *adversus majestatem populi romani*; the claim made by Jesus to be a king; and the result that his judge became convinced that the claimant was opposed neither to the public peace nor to the civil supremacy of Rome. The result is explained only by the dialogue, recorded exclusively in John, which shows the accused and the Roman meeting on the highest levels of the thought and conscience of the time. "I am come to bear witness unto the truth . . . Pilate answered, What is truth?" Estimates of Pilate’s attitude at this point have varied infinitely, from Tertullian’s, that he was "already in conviction a Christian"—*jam pro sua conscientia Christianus*—to Bacon’s "jesting Pilate," who would not stay for a reply. We know only that to his persistent attempts thereafter to get his proposed verdict accepted by the people, came their fatal answer, "Thou art not Caesar’s friend," and that at last he unwillingly ascended the *bema* (in this case a portable judgment-seat, brought for the day outside the Praetorium), and in such words as *Ibid. ad crucem* "delivered Him to be crucified."

Pilate’s place in the Christian tragedy, and perhaps also in the Creed, stimulated legend about him in two directions, equally unhistorical. The *Gospel of Nicodemus*, written by a Christian (possibly as early as Tischendorf thought, as the middle of the 2nd century), repeats the trial in a dull and diluted way; but it not only alleged evidence of the Resurrection, but the splendid vision of the *descensus ad inferos*—the whole professing to be recorded in the *Acta Pilati* or official records of the governor. The Epistola *Pilati* gives Pilate’s supposed account to Tiberius of the Resurrection; and the *Paradosis Pilati* relates how Tiberius condemned him and his wife Procla or Prucola, both Christian converts. All this culminates in Pilate being canonized in the Abyssinian Church (June 25), and his wife in the Greek (Oct. 27). On the other hand the *Mors Pilati* tells how when condemned by the emperor he committed suicide; and his body, thrown first into the Tiber and then the Rhine, disturbed both waters, and was driven north into "Losania," where it was plunged in the gulf near Lucerne and below Mt Pilatus (originally no doubt *Pilatus* or cloud-capped), from whence it is raised every Good Friday to sit and wash unavailing hands.

**Bibliography.**—For legends see Tischendorf’s *Evangelia apocrypha* (1865) and *Apocryphal Gospels*, Ante-Nicene Lib. (1886).
The earlier Pilate literature, to the extent of 110 treatises, chiefly of the 17th and 18th centuries, is enumerated in G. A. Müller's Pontius Pilatus der fünfte Prokuror von Judäa (Stuttgart, 1888). See in loco in the following English or translated histories of the life or time of Jesus, Theodor Keim, E. Sähli, and others, J. P. Lange, Bernhard Weiss and F. W. Farrar: Expositor (1884) p. 107 and (1900) p. 59; also H. Peter, "Pontius Pilatus, der römische Landpfleger in Judäa," in Neue Jahrb. f. d. kl. Altertum (1907). Sir John Frederick Scott is also well attested (1873), p. 87, starts the question, "Was Pilate right in crucifying Christ?" his somewhat paradoxical answer is criticised in The Trial of Jesus Christ, a legal monograph, by A. Taylor Innes (1899).

(1. T. L.)

PILATUS—PILGRIM

603

PILATUS, LEO, or LEONTUS [LEONZIO PIALTO] (d. 1366), one of the earliest promoters of Greek studies in western Europe, was a native of Thessalonica. According to Petrarch, he was an Italian, and as a Calabrian, who posed as a Greek in Italy and as an Italian abroad. In 1360 he went to Florence at the invitation of Boccaccio, by whose influence he was appointed to a lectureship in Greek at the Studio, the first appointment of the kind in the west. After three years he accompanied Boccaccio to Venice on a visit to Petrarch, whom he had already met at Padua. Petrarch, disgusted with his manners and habits, despached him to Constantinople to purchase MSS. of classical authors. Pilatus soon tired of his mission and, although Petrarch refused to receive him again, set sail for Venice. Just outside the Adriatic Gulf he was struck dead by lightning. His chief importance lies in his connexion with Petrarch and Boccaccio. He made a bald and almost word for word translation of Homer into Latin prose for Boccaccio, subsequently sent to Petrarch, who owed his introduction to the poet to Pilatus and was anxious to obtain a complete translation. Pilatus also furnished Boccaccio with the material for his genealogy of the gods, in which he made an ostentatious display of Greek learning.

See Gibbon, Decline and Fall, ch. 66; G. Voigt, Die Wiederbelebung des classischen Alterthums (1893); H. Hody, De Graecis illustribus (1742); G. Taraboschi, Storia della letteratura italiana, v. 691.

PILAU, a favourite Eastern dish, consisting essentially of rice, boiled with mutton or other meat, fowl or fish, and flavoured with spices, raisins, &c. The word appears in Persian, Turkish, and Urdu, and has been adopted in European languages. The form pilaji, showing the Turkish pronunciation, is also common.

PILCHARD (in earlier 16th century forms psylcker, pilchár; of unknown origin; the Fr. pilseir is derived from Eng.), Clupea pilchardus, a fish of the herring family (Clupeidae), abundant in the Mediterranean and on the Atlantic coast of Europe, north to the English Channel. Sardine is another name for the same fish, which, on the coast of Brittany and Normandy is also called pil, pilseir, or pilis. It is applied also to certain other European species of Clupea. The operculum is sculptured with ridges radiating and descending towards the suboperculum; the scales are large, about thirty along the lateral line, deciduous; the ventral fins are inserted below, or nearly below, the middle of the base of the dorsal fin; the dorsal fin has seventeen or eighteen, the anal from nineteen to twenty-one rays. A small blackish spot in the scapular region is very constant, and sometimes succeeded by other similar marks. There are no teeth on the palate; pyloric appendages exist in great numbers; the vertebrae number fifty-three. The pilchard is one of the most important fishes of the English Channel. It spawns at a distance from the shore, and its eggs are buoyant, like those of many other marine fishes and unlike those of the herring, which are adhesive and demersal, i.e. develop under water. The egg of the pilchard is very easily distinguishable from other pelagic eggs by the unusually large space separating the vitalline membrane from the contained ovum. Spawning takes place in summer, the season extending from June to October. When commencing their migrations towards the land the shoals consist of countless numbers, but they break up into smaller companies near the shore. Pilchards feed on minute crustaceans and other pelagic animals and require two or three years before they attain their full size, which is about 10 in. in length. The sardines of the west coast of France, which are tinned in oil for export, are immature fish of the same stock as those taken

on the coasts of Cornwall; they are 5 to 7½ in. in length, and though such fish occur also on the Cornish coast it is only in small numbers and for brief periods. In the Mediterranean the sardine does not exceed 7½ in. in length when mature. On the Pacific coast of America, in New Zealand and in Japan a pilchard occurs (Clupea sagonos) which in its characters and habits is so similar to the European pilchard that its general utilization is deserving of attention. Immense shoals are reported to visit the east coast of Otago every year in February and March. Clupea scombrina is the "oil sardine" of the east coast of India.

(J. T. C.)

PILE, an homonymous word, of which the main branches are (1) a heap, through Fr. from pila, pillar; (2) a heavy beam used in making foundations, literally a pointed stake, an adaptation of Lat. pilum, javelin; (3) the nap on cloth, Lat. pilus, hair. In the first branch the Lat. pila (for pilsa, from root of pansere, to fasten) meant also a pier or mole of stone, hence any mass of masonry, as in Fr. pêle. In English usage the word chiefly means a "heap" or "mass" of objects laid one on the top of the other, such as the heap of faggots or other combustible material on which a dead body is cremated, "funeral pile," or on which a living person is burnt as a punishment. It also is applied to a large and lofty building, and specifically, to a stand of arms, "piled" in military fashion, and to the series of plates, "galvanic" or "voltaic piles," in an electric battery. The modern "head and tail" of a coin was formerly "cross and pile," Fr. crois et pile, in modern Fr. face et pile. In the older apparatus for minting the die for the reverse was placed on a small upright pillar, pile, the other on a puncheon known as a "trussel" (Fr. trousseau). The common name of the disease of haemorrhoids (q.v.) or "piles" is probably an extension of this word, in the sense of mass, swelling, but may be referred to the Lat. pila, ball. The name of the pilum, or heavy javelin (lit. pounder, pesle, from pinsere, pisere, to beat), the chief weapon of the ancient Roman infantry, was adopted into many Teutonic languages in the sense of dart or arrow, e.g. Germ. Pfeil; in English it was chiefly used of a heavy stake with one end sharpened, and driven into swampy ground or in the bed of a river to form the first foundations for a building; the primitive lake-dwellings built on "piles" are also known as "pile-dwellings." For the use of piles in building see FOUNDATIONS and BRIDGES. In heraldry a charge represented by two lines meeting in the form of an arrow head is known as a "pile," a direct adaptation probably of the Lat. pilum. The division of this intrusive word, followed here, is that adopted by the New English Dictionary; other etymologists (e.g. Skel, Etym. Dict., 1859) arrange the words and their Latin originals somewhat differently.

PILGRAM, a wanderer, traveller, particularly to a holy place (see PILGRIMAGE). The earliest English forms are plegim- or plegeim, through Fr. pelgrin (the original O. Fr. pelegrin is not found), from Lat. peregrinus, a stranger, foreigner, particularly a resident alien in Rome (see PRAETOR, and ROMAN LAW). The Lat. pereger, from which peregrinus is formed, meant "from abroad," "travelled through many lands" (per, through, and ager, country).

It was customary for pilgrims to bring back as proof of their pilgrimage to a particular shrine or holy place a badge, usually made of lead or pewter, bearing some figure or device identifying it with the name or place. These "pilgrim signs" are frequently alluded to in literature—notably in the Canterbury Tales and in Piers Plowman. The British Museum and the Museum Cluny in Paris have fine collections of them, mainly obtained from the Thames and the Seine. The badges were generally worn fastened to the pilgrim’s hat or cape. Among the best known are those of the cockle or scallop shell of St. James of Compostella in Spain; the "vermice," a representation of the miraculous head of Christ; the vera icon, true image, on St. Veronica’s handkerchief, at Rome, or of the Abgar portrait at Genoa, of "a vermice hadde he sowe on his cappe" (Cant. Tales, "Pro.") 683); the Amiens badge of the head of John the Baptist on the charger, the cathedral claiming the custody of the relic from 1206 (fig. 1); and the palm branches or cross of palm leaf, the
PILGRIMAGE

badge of the "Palmers" pilgrimage to the Holy Land. The most common of the English pilgrims' signs are those of the shrine of Thomas Becket at Canterbury, the greatest centre of pilgrimage in England. These take a variety of forms, sometimes a simple T, sometimes a bell marked *campana Thome*, the Canterbury bell, most often a figure of the saint, sometimes seated, sometimes riding on a horse, and carrying his episcopal cross, and with hand uplifted in benediction (fig. 2). Sometimes the badges took the shape of small *amplulae* or vases, as in the case of the badges of the shrine of Our Lady of Walsingham, which were marked with a W and crown.

The English "Pilgrims' Way."—From Winchester, in Hampshire, to Canterbury, in Kent, runs a road or way which can still be traced, now on the present made roads, now as a lane, bridle path, or cart track, now only by a line of ancient yews, hollies or oaks which once bordered it. To this old track the name of "pilgrims' way" has been given, for along it passed the stream of pilgrims coming through Winchester from the south and west of England and from the continent of Europe by way of Southamptom to Canterbury Cathedral to view the place of the martyrdom of Thomas Becket, in the north transept, to the relics in the crypt where he was first buried after his murder, in 1170, and the shrine in the Trinity Chapel which rose above his tomb after the translation of the body in 1220. There were two festivals for the pilgrimage, on the 29th of December, the day of the martyrdom, and on the 15th of July, the day of the translation. The summer pilgrimage naturally became the most popular. In 1538 the shrine was destroyed and the relics of the saint scattered, but the great days of the pilgrimage had then passed. Erasmus gives a vivid picture of the glories of the shrine and of all that was shown to the pilgrims on his visit with Colet to Canterbury in 1514.

The principal villages, towns and places near or through which the way passed are as follow: Winchester, Alresford, Ropley, Alton, Farnham (here the way follows the present main road), Seale, Puttenham, by the ruined chapel of St. Catherine, outside Guildford, near where the road crosses the Wey above Shalford, and by the chapel of St. Martha, properly of the "martry," now restored and used as a church. Albury, Sere, Gomshall, Dorking (near here the Mole is crossed), and the southern slope of Boxhill southwards to Reigate, then through Gatton Park, Merstham, Otford, Wrotham, after which the Medway was crossed, Burham, past the megalithic monument *Kit's Coty House*, and the site of Boxley Abbey, the oldest after Waverley Abbey of Cistercian houses in England, and famous for its miraculous image of the infant saint Rumbold, and the still more famous winking rood or crucifix. The road passes next by Hollingbourne, Lenham and Charing. At Otford, Wrotham and Charing were manor-houses or rather palaces of the archbishops of Canterbury; at Hollingbourne was a manor of the priors of Christchurch.

1 Shalford Fair, the chapels on the two hills and the Surrey hills are probably the scene of Bunyan's Pilgrim's Progress, see E. Rénéoud James, *Notes on the Pilgrim's Way in West Surrey* (1871).

Hollingbourne come Westwell, Eastwell, Boughton Aluph, Godmersham, Chilham Castle, and then at Harbledown, where are the remains of the Hospice of St Nicholas, the road joins Watling Street, by which came the main stream of pilgrims from London, the North and the Midlands.

This road, although its name of the Pilgrims' Way has for long confined it to the road by which the pilgrims came to Canterbury from Winchester, follows a far older track. Right back into British and even older times the main direction which commerce and travellers followed across southern and western England to the Straits of Dover and the Continent lay from Canterbury along the southern chalk slope of the North Downs to near Guildford, then by the Hog's Back to Farnham. At this point the oldest track went across Salisbury Plain towards Stonehenge and so on to Cornwall. From Farnham westward the only portion of this that can now be traced is a small portion that still bears the name of the Harrow (i.e. hoary, old) road. It was in early times abandoned for the road from Winchester to which the stream of travel and commerce from the Continent and the south and south-west of England was diverted.

The "pilgrims' way" has been traced fully in Mrs Ady's book *The Pilgrims' Way* (1893), and the older track in the fullest detail in Hilaire Belloc's *The Old Road* (1904).

The American "Pilgrim Fathers."—In American history the name "Pilgrims" is applied to the earliest settlers of the colony of Plymouth, Massachusetts, and more specifically to the first company of emigrants, who sailed in the "Mayflower" in 1620. They were from the beginning Separatists from the Church of England; they had established Independent (Congregational) churches at Scrooby and Gainsborough early in the 17th century, and some of them had fled to Amsterdam in 1608 to avoid persecution, and had removed to Leiden in the following year. They sailed from Delfshaven late in July 1620, from Southampton on the 5th of August, from Plymouth on the 6th of September, and late in December 1620 founded the colony of Plymouth, Massachusetts. See MASSACHUSETTS; PLYMOUTH, and MAYFLOWER.

PILGRIMAGE (Fr. *pèlerinage*, Lat. *peregrinatio*), a journey undertaken, from religious motives, to some place reputed as sacred. These journeys play an important role in most pre-Christian and extra-Christian religions: in the Catholic Church their acceptance dates from the 3rd and 4th centuries.

1. Pilgrimage in pre-Christian and non-Christian Religions.—To the Germanic religions the pilgrimage is unknown. On the other hand, it is an indigenous element, not only in the creeds of Asia, but in those of the ancient seats of civilization on the Mediterranean. The fundamental conception is always that the Deity resides—or exercises a peculiarly powerful influence—in some definite locality; and to this locality the devout repair, either in reverence of their god, or in quest of his assistance and bounty. Thus, as the cult of a particular divinity spreads farther and farther, so the circle expands from which are drawn those who visit his sanctuary.

One of the oldest homes of the pilgrimage is India. There the clergy of devout persons tend more especially to the Ganges—the hallowed river of Hindu cult. From the Ganges lies Benares, the holy city of Brahminism: and to look on Benares, to visit its temples, and to be washed clean in the purifying river, is the yearning of every pious Indian. Even Buddhism—originally destitute of ceremonial—has adopted the pilgrimage; and the secondary tradition makes Buddha himself determine its goals: the place where he was born, where he first preached, where the highest insight dawned on him, and where he sank into Nirvana. The four ancient sacred resorts are Kapilavastu, Gaya, Benares and Kusinagara.

In Syria, the temple of Artagatis in Hierapolis was an immortal resort of pilgrims. In Phoenicia, a similar significance was enjoyed by the shrine of Astarte, on the richly-watered source of the river Adonis, till, as late as the 4th century after Christ, it was destroyed by Constantine the Great. In Egypt, the great annual and monthly festivals of the indigenous gods.
gave rise to all manner of religious expeditions. Even among the Israelites, the visitation of certain cult-centres prevailed from remote antiquity; but, when the restriction of Yahweh-worship to Jerusalem had doomed the old shrines, the Jewish pilgrimages were directed solely to the sanctuary on Mt Moriah.

Among the Greeks the habit was no less deeply rooted. Just as the inhabitants of each town honoured their tutelary deity by solemn processions to his temple, so, at the period of the Olympic games, the temple of Zeus at Olympia formed the goal of multitudes from every Hellenic city. No less powerful was the attraction exercised by the shrines of the oracular divinities, though the influx of pilgrims was not limited to certain days, but, year in and year out, a stream of private persons, or embassies from the city-states, came flowing to the temple of Apollo at Delphi, or the shrine of the hero Argus. The unification of the peoples of antiquity in the Roman Empire, and the resultant amalgam of religions, gave a powerful impetus to the custom. For, as East and West still met at the old sanctuaries of Greece, so—and yet more—Greece and Rome repaired to the temples of the southern and eastern deities. In the shrine of Isis at Philae, Europeans set up votive inscriptions on behalf of their kindred far away at home, and it may be surmised that even among the festival crowds at Jerusalem a few Greeks found place (John xii. 20).

The pilgrimage, however, attained its zenith under Islam. For Mahomet proclaimed it the duty of every Mussulman, once at least in his life, to visit Mecca; the result being that the birthplace of the Prophet is now the religious centre of the whole Mahomedan world (see Mahomedan Religion; Caravan; Mecca).

II. The Pilgrimage under Christianity.—The pilgrimages of Christianity presuppose the existence of those of paganism; but it would be an error to maintain that the former were a direct development of the latter. For primitive Christianity was devoid of any point by which these journeys of devotion might naturally have been suggested. It was a religion without temples, without sanctuaries, and without ceremonial. The saying of the Johannine Gospel—that God is to be adored neither in Jerusalem nor on Gerizim, but that His true worshipper must worship Him in spirit and in truth—is in complete harmony with the old Christian piety. And, accordingly, in the ancient Christian literature, we find no trace of a conception that the believer in Christ should visit a definite place in order to pay homage to his Master. The evolution of the Christian pilgrimage moved on other lines.

Cicero finely observes that, in Athens, the glorious architecture caused him less pleasure than did the thought of the great men whose work was done in its midst—"how here one had lived, and there fallen asleep; how here another had disputed, and there lay buried" (De Legg. ii. 2). This feeling was not weakened by the advent of Christianity, in fact, we may say that it was appreciably strengthened. Cicero had already compared the sites consecrated by the memory of some illustrious name with those hallowed by recollections of a loved one. But with the Christian, when his Redeemer was in question, both motives coincided: for there the greatest was also the dearest. In this divine mansion, Jesus, we find the key to the origin of the Christian pilgrimage: the faithful repaired to those places which were invested with memories of their Lord's earthly life. And these journeys must certainly date from the 2nd century. For Origen (d. 254) mentions that in Bethlehem the cave was shown where Christ was born, and in it the manger in which Mary made the bed of her child. The site must have been much visited long before this, since Origen remarks that it was common knowledge, even among the infidels, that there was the birthplace of that Jesus whom the Christians worshipped (Contr. Cels. i. 51). But those who visited Bethlehem must certainly have visited Jerusalem and the places there, so rich in memorials of their Master. And the sympathy of Christendom soon led them beyond this immediate circle. The anonymous author of the Cohortatio ad Graecos, a work of the 3rd century, visited the remnants of those cells, in which—so legend related—the seventy interpreters laboured on their version of the Old Testament: nor, when he came to Cumae in Campania, did he fail to have shown him the old shrine of the Sibyl (Coh. ad Gr. 13 and 37). Soon we begin to hear the names of the pilgrims. In the course of the 3rd century, as Jerome relates, Firmilian, bishop of Caesarea in Cappadocia, travelled to Palestine to view the sacred places (De Vir. ill. 54); while, according to Eusebius, a second bishop from Cappadocia, Alexander by name, visited Jerusalem in order to pray and acquaint himself with the holy sites, and was there invited by the community to remain with them and assume the episcopate of the aged Narcissus (Hist. ecc. vi. 11). With regard to his own times—the early years of the 4th century—the same authority recounts that believers kept streaming to Palestine from all regions, there to witness the shrine of the three Kings, and the Church of the Holy Sepulchre. (Demonstr. eun. vi. 18).

This statement, that the Christians of the 3rd and 4th centuries were in the habit of visiting Jerusalem for prayer, proves that the non-Christian conception of the religious pilgrimage had already entered the sphere of Christian thought. That men travelled for purposes of prayer implies acceptance of the heathen theory of sanctuaries which it is an act of piety to visit. We may regret the fact, for it sullied the purity of primitive Christian thought. Nevertheless, it is clear that the development was inevitable. As soon as the non-Christian ideas of priests, sacrifices, houses of the god, and so forth, were naturalized in the Christianity of the 3rd century, it was but a short step to the belief in holy places

III. The Pilgrimage at the Ancient Church.—In the passages cited above, Bethlehem and the Mount of Olives figure as the main goal of the pilgrim: and on the Mount of Olives the mind must naturally turn to the Garden of Gethsemane and the scene of the Ascension. It may seem surprising that there is no mention of Golgotha and the Sepulchre. But the visitation of these sites was rendered impossible to the Christians by the destruction of Jerusalem and the erection of the town of Aelia Capitolina. They had not forgotten them; but the grave was concealed under a mound of earth and stones—a profanation probably dating from the siege of the city and Titus's attack on the second wall. On the summit of this mound there stood, in the days of Eusebius, a sanctuary of Venus (Eus. Vit. Const. iii. 26, 30). The Sepulchre and the Hill of Olives were declared a sepulchral reserve (ib. 20); and, consequently, before the era of Constantine, the one holy site in the town of Jerusalem was the so-called Coenaculum, which received its name in later years. It lay south of the city, near the outer wall, and, if Epiphanius is to be believed, was already in existence when Hadrian (119-138) visited Jerusalem (De mens. 14). It was regarded as the house, in which—according to the Acts of the Apostles (xii. 12 sqq.)—Mary, the mother of John Mark, lived; and the belief was that there the Lord held the Last Supper, and that there the eleven assembled after the Ascension. It was there, also, that the scene of the Pentecostal effusion of the Spirit was laid (cf. Cyrill. Hier. Cat. xvi. 4).

The pilgrimage to Palestine received a powerful impetus from the erection of the memorial churches in Jerusalem, under Constantine, and, later, by Eusebius in his biography of the emperor (iii. 25 sqq.). At the order of Constantine, the shrine of Venus above mentioned was destroyed, and the accumulated rubbish removed, till the ancient rock-foundation was reached. There the cave was discovered in which Joseph of Arimathea had laid the body of Jesus; and above this cave and the Hill of the Crucifixion the imposing church of the Holy Sepulchre was built (A.D. 326-336). The churches in Bethlehem and on the Mount of Olives were erected by Helena, the mother of Constantine, who herself undertook the pilgrimage to the Holy Land. These churches were then endowed with new sanctuaries of miraculous powers; and relics of Christ were found in the shape of the Cross and the nails. Eusebius, the contemporary of Constantine, is silent on this point. To his continuators, on the other hand, it is an established fact that Helena brought all three crosses to light, and ascertainment
PILGRIMAGE

the genuine Cross by the instrumentality of a miracle, in addition to discovering the nails of the Crucifixion (Rufin. i. 7; Socr. i. 17; Sozomen. ii. 1; Theod. i. 27). It is impossible to fix the date at which the supposititious relics were introduced into the church of the Sepulchre: it is certain, however, that in the 5th century the Cross was there preserved with scrupulous reverence, and accounted the highest treasure of the sanctuary.

After the 4th century, monks and nuns begin to form no inconsiderable part of the pilgrimages—a fact which is especially manifest from the numerous notices to be found in Jerome, and the narratives of Theodoret in the Historia religiosa. In fact, many were inclined to regard a journey to Jerusalem as the bounden duty of every monk—an exaggerated view which led to energetic protests, especially from Gregory of Nyssa, who composed a monograph on the pilgrimages (De iis qui adoeunt Hierosol.). Jerome, like Gregory, insists on the point that residence in Jerusalem has in itself no religious value: it is not locality, but character, that avails, and the gates of Heaven are as open in Britain as in Jerusalem (Ep. 58, 3). These utterances, however, must not be misinterpreted. They are not directed against the pilgrimage in itself, nor even against the belief that prayer possesses special efficacy on sacred ground, but solely against the exaggerated developments of the system.

The theologies of the 4th and 5th centuries were at one with the masses in recognizing the religious uses of the pilgrimages. Jerome in particular considered it an act of faith for a man to offer his prayers where the feet of the Lord had stood, and the traces of the Birth, of the Cross, and of the Passion were still to be seen (Ep. 47, 2).

We may gain some impression of the mood in which the pilgrims completed their journey, when we read how Paula, the friend of Jerome, expresses herself on her visit to the church of the Sepulchre: “As oft as we enter its precincts we see the Savour of God in the shroud, and the angel seated at the feet of the dead!” (Hieron. Ep. 46, 2). She assured Jerome that, in the church of the Nativity at Bethlehem, she beheld, with the eye of faith, the Christ-child wrapped in swaddling clothes (Ep. 108, 10). But with these thoughts, others of an entirely different stamp were frequently blended. Pilgrimages were conceived as means to ensure an answer to particular prayers. So, for example, Eudocia, the wife of Theodosius II., vowed to undertake a pilgrimage to Jerusalem, if she should see her daughter married. (Socr. Hist. eccl. vii. 47). And, closely as this approaches to pagan ideas, the distinction between paganism and Christianity is completely obliterated when we find the hermit Julian and his companions travelling to Sinai in order to worship the Deity there resident (Theod. Hist. Rel. 2).

With the number of the pilgrims the number of pilgrimage-resorts also increased. Of Jerusalem alone Jerome relates that the places of prayer were so numerous that it was impossible to visit them all in one day (Ep. 46, 6). In the Holy Land the list was still longer: the natives were ready to show everything for which the foreigners inquired, and the pilgrim was eager to credit everything. In her expedition to the East, the Paula mentioned above visited, among other places, Sarepta and Caesarea. In the first-named place she was the tower of Elijah; in the second, the house of Cornelius, that of Philip, and finally the grave of the four virgins. At Bethlehem she saw, in addition to the church of the Nativity, the grave of Rachel; at Hebron the hut of Sarah, in which the swaddling clothes of Isaac and the remains of Abraham’s oak were on view (Hieron. Ep. 108). A similar picture is given in the Tractat of the so-called Silvia Aquitana, who, seems, in reality, to have been a Spanish nun, named Etheria or Eucheria. She went as a pilgrim to Jerusalem (c. 380), and from there traversed the whole of Palestine, in order to visit every site which was consecrated by memories of the Lord’s earthly life. Nor did she neglect the scenes of patriarchal history. Of greater antiquity is the concise account of his travels by an anonymous pilgrim, who, in A.D. 333, undertook the journey from Bordeaux to Palestine. The Itinerary of the African Theodosius who visited the East between A.D. 520 and A.D. 530 is of later date (P. Geyer, Itin. hierosol. sacc. iv.-viii.).

While pilgrimage-resorts were thus filling the East, their counterparts began to emerge in the West. And here the starting-point is to be found in the veneration of martyrs. In the West Care for the tombs of martyrs was sanctioned by immemorial custom of the Church; but, in this case also, a later age failed to preserve the primitive conception in its purity; and Augustine himself was obliged to defend the usage of the Church from the imputation that it implied a transference of heathen ceremonial to the sphere of Christianity (Contr. Faust. xx. 21). The martyrs were the local heroes of particular communities; but there were men whose life and death were of significance for the whole of Christendom—the apostles. Of these Peter and Paul had suffered martyrdom in Rome, and it was inevitable, from the nature of the case, that their graves should soon become a resort, not only of Romans born, but of strangers also. True, the presbyter Caecilius (c. 200) who first mentions the situation of the apostolic tombs on the Vatican and the road to Ostia, and refers to the memorials there erected, has nothing to say of foreign Christians journeying to Rome in order to visit them. And though Origen travelled to Rome, it was not to view the graves of dead men, but to establish relations with the living flock (Euseb. Hist. eccl. ii. 25; vii. 14; 10); still, it is certain that the Roman cemeteries were visited by numerous pilgrims even in the 3rd century: for the earliest graffiti in the papal crypt of the Coeneterium Callisti must date from this period (De Rossi, Roma sotterr. i. 253 sqq.; Kraus, Rom. Sotl. 148 sqq.). And if the tombs of the popes were thus visited, so much more must this hold of the tombs of the apostles. After these, the most frequented resort at Rome in the 4th century was the grave of Hippolytus. The pope Prudentius describes, on the day of the martyr’s death, an immeasurable multitude of pilgrims locked round the site. Even on ordinary days arrivals and departures were almost incessant—foreigners being everywhere seen mingled with the native Latins. They poured balsam on the sepulchre of the saint, washed it with their tears, and covered it with their kisses, in the belief that they were thus assuring themselves of his intercession or testifying their gratitude for his assistance. Prudentius says of himself, that whenever he was sick in soul or body, and prayed there, he found help and returned in cheerfulness: for God had vouchsafed his saint the power to answer all entreaties (Perist. xi. 175 sqq.). Paulinus of Nola (d. 431) concurs—his custom being to visit Ostia each year, and Rome on the apostolic anniversaries (Ep. 20, 2; 45, 1). Next to Rome the most popular religious resort was the tomb of Felix of Nola (August. Ep. 78, 3); while in Gaul the grave of St Martin at Tours drew pilgrims from all quarters (Paul. Nys. Ep. 17, 4). Africa possessed no sanctuary to compete with these; we learn from Paulinus of Nola (c. 400) that the tomb of Cyprian seems to have been visited even by a Gaul (Dial. i. 3).

The motive that drew the pilgrims to the graves of the saints is to be found in the conviction, expressed by Prudentius, that there divine succour was certain; and hence came the belief in a never-ending series of miracles there performed (cf., e.g. Ennod. Ticin. Lib. pro syn. p. 315). Doubt was unknown. St Augustine observes that, though Africa was full of martyrs’ tombs, no miracle had been wrought at them so far as his knowledge extended. This, however, did not lead him to doubt the truth of those reported by others—a fact that is somewhat surprising when we reflect that the phenomenon caused him much diseased and perplexity. Who, he asks, can fathom the design of God in ordaining that this should happen at one place and not at another? And even yet he acquiesces in the conclusion that God, who gives every man his individual gift at pleasure, has not willed that the same powers should have efficacy at every sepulchre of the saints (Ep. 78, 3).

IV. The Pilgrimage in the Middle Ages.—The medieval Church
adopted the custom of the pilgrimage from the ancient Church. The young Germanic and Romanic nations did precisely as the Greeks and Romans had done before them, and the motives of these devotional journeys—now much more difficult of execution in the general decay of the great world-system of commerce—remained much the same. They were undertaken to the honour of God (Pipp. Cap. 754-755, c. 4), for purposes of prayer (Ann. Hild. 992), or in quest of assistance, especially health (Vita Galli, ii. 37; Vita Liudg. iii. 10). But the old causes were reinforced by others of at least equal potency. The medieval Church was even more profoundly convinced than its predecessor that the miraculous power of Deity attached to the bodies of saints and their relics. But the younger nations—French, English and German—were scantily endowed with saints; while, on the other hand, the belief obtained that the home-counties of Christianity, especially Rome and Jerusalem, possessed an inexhaustible supply of these sanctified bodies. Pilgrimages were consequently undertaken with the intention of securing relics. At first it was enough to acquire some object which had enjoyed at least a mediate connexion with the hallowed corpse. Gregory of Tours (d. 594) mentions one of his deacons who made a pilgrimage into the East, in order to collect relics of the Oriental saints; and, on his return, visited the grave of the bishop Nicetius (St Nizier, d. 573) in Lyons, where he still further increased his store. His testimony showed how relics came to be distributed among the populace: one enthusiast took a little wax dropped from the taper; another, a portion of the dust which lay on the grave; a third, a thread from the cloth covering the sarcophagus; and he himself plucked the flowers which visitors had planted above the tomb. Such were the memorials with which he returned; but the universal belief was that something of the miraculous virtue of the saint had passed into these objects (Vit. patr. 8, 6). Before long, however, these humble trophies failed to content the pilgrims, and they began to devote their efforts to acquiring the actual bodies, or portions of them—frequently by honest means, still often by trickery. One of the most attractive works of early medievalism—Einhard’s little book, _Translatio Martellini et Petri_—gives a vivid description of the methods by which the bodies of the two saints were acquired and transported from Rome to Seligenstadt on the Main.

Far more important consequences, however, resulted from the fact that the medieval mind associated the pilgrimage with the forgiveness of sins. This conception of the pilgrimage, as a means of expiation or a source of pardon for wrong, was foreign to the ancient Church. It is quite in accordance with the keener consciousness of sin, which prevailed in the middle ages, that the expiatory pilgrimage took its place side by side with the pilgrimage to the glory of God. The pilgrimage became an act of obedience; and, in the books of penance (Poenitentialia) which date from the early middle ages, it is enjoined—whether for a definite period (e.g. _Poen. Vallicc. i._ c. 157; _Poen. Cont._ i. 246) or for life (_Poen. Cummanni_, vol. 12, Casin. 24)—as an expiation for many of the more serious sins, especially murder or the less venial forms of unchastity. The place to be visited was not specified; but the pilgrim, who was bound by an open letter of his bishop to disclose himself as a penitent, lay under the obligation, wherever he went, to repair to the churches and—more especially—the tombs of the saints, and there offer his prayers. On occasion, a chain or ring was fastened about his body, that his condition might be obvious to all; and soon all manner of fables gained currency: how, here or there, the iron had sprung apart by a miracle, in token that the sinner was thereby absolved by God. For instance, the _Vita Liudgerii_ recounts the history of a fratricide who was condemned to this form of pilgrimage by Jonas, bishop of Orleans (d. 843): he wore three iron rings round his body and arms, and travelled bare-footed, fasting, and devoid of linen, from church to church till he found pardon, the first ring breaking by the tomb of St Gertrude at Nivelles, the second in the crypt of St Peter, and the third by the grave of Liudger. The pilgrim-

age with a predetermined goal was not recognized by the books of penance; but, in 1059, Peter Damiani imposed a pilgrimage to Rome or Tours on the clergy of Milan, whom he had absolved (_Ada mediat. patrol. lat. 145, p. 98_).

As the system of indulgences developed, a new motive came to the fore which rapidly overshadowed all others: pilgrimages were now undertaken to some sacred spot, simply in order to obtain the indulgence which was vested in the respective church or chapel. In the 11th century the indulgence consisted in a remission of part of the penance imposed in the confessional, in return for the discharge of some obligation voluntarily assumed by the penitent. Among these obligations, a visit to a particular church, and the bestowal of plous gifts upon it, held a prominent place. The earliest instance of the indulgential privilege conferred on a church is that granted in 1016 by Pontius, archbishop of Arles, to the Benedictine abbey of Montmajour (Mons Major) in Provence (d’Achery, _Spicil. iii._ 383 seq.). But these dispensations, which at first lay chiefly in the gift of the bishops, then almost exclusively in that of the popes, soon increased in an incessant stream, till at the close of the middle ages there were thousands of churches in every western country, by visiting which it was possible to obtain an almost indefinite number of indulgences. But, at the same time, the character of the indulgence was modified. From a remission of penance it was extended, in the 13th century, to a release from the temporal punishment exacted by God, whether in this life or in purgatory, from the repentant sinner. And, from an absolusion from the consequences of guilt, it became, in the 14th and 15th centuries, a negation or the guilt itself; while simultaneously the opportunity was offered of acquiring an indulgence for the souls of those already in purgatory. Consequently, during the whole period of medievalism, the number of pilgrims was perpetually on the increase.

So long as the number of pilgrims remained comparatively small, and the difficulties in their path proportionately great, they obtained open letters of recommendation from their bishops to the clergy and laity, whose presence at them lodging in convents and charitable foundations, in addition to the protection of public officials. An instance is preserved in Markulf’s _formulary_ (ii. 40). To receive the pilgrim and supply him with alms was always considered the duty of every Christian: Charlemagne, indeed, made it a legal obligation to withhold neither roof, hearth, nor fire from them (_Admon. gent._ 780, c. 75; _Cap. Miss. 802_, c. 27).

The most important places of resort both for voluntary and involuntary pilgrimages, were still Palestine and Rome. On the analogy of the old _Itineraria_, the abbot Adamann of Iona (d. 704) now composed his monograph _De locis sanctis_, which served as the basis of a similar book by the Venerable Bede (d. 735)—both works being edited in the _Ihln. hiersol._

His authority was a Frankish bishop named Arculf, who resided for nine months as a pilgrim in Jerusalem, and visited the remaining holy sites of Palestine and Syria in addition to Alexandria and Constantinople. Of the later itineraries the _Descrip. terrae sancte_, by the Dominican Burchardus de Monte Sion, enjoyed the widest vogue. This was written between the years 1285 and 1295; but books of travel in the modern tongues had already begun to make their appearance. The initiative was taken by the French in the 12th and 15th centuries, and the Germans followed in the 14th and 15th; while the _Book of Wayes to Jerusalem of John de Maundeville_ (c. 1338) attained extreme popularity, and was translated into almost all the vernacular languages. Most pilgrims, probably, contented themselves with the brief guide-books which seem to have originated in the catalogue of indulgences. In later periods, that of Rombber a Kyrse, printed at Venice (1510), stood high in favour.

A long list might be compiled of men of distinction who performed the pilgrimage to Palestine. In the 8th century one of the most famous is the Anglo-Saxon Willibald, who died in 751 as bishop of the Frankish diocese of Eichstätt. He left his home in the spring of 729, accompanied by his father and brother. The pilgrims traversed France and Italy, visiting

**PILGRIMAGE**

**New Motives.**
every religious resort; in Lucca the father died, and the brother remained behind in Rome. Early in 722 Willibald began his expedition to the Holy Land alone, except for the presence of two companions. He traveled past Naples to Syracuse, then on shipboard by Cos and Samos to Ephesus, and thence through Asia Minor to Damascus and Jerusalem. On St Martin’s day, in 724, he arrived in the Holy City. After a prolonged stay in the town and its environs, Willibald proceeded (727) to Constantinople, and in 729 returned to Italy. Such is the account given by the nun of Heidenheim in her biography of Willibald; and her version is probably based on notes by the pilgrim himself (Mon. Germ. hist. scr. xv. 86 sqq.). In the 9th century the French monk Bernard visited Palestine with two companions, and afterwards wrote a simple and trustworthy account of his journey (Patrol. lat. 121, 556 sqq.). In the 10th century Conrad, bishop of Constance (934-979), performed the pilgrimage to Jerusalem three times (Vita Chunoir. 7); and to the same period belong the first written pilgrimages to Jerusalem of whom we have any cognisance—Hilida, mother of Gero, archbishop of Cologne (Thietm. Chron. ii. 16), and the countess Hademod of Ebersberg (Chron. eberzb.). The leaders, moreover, of the monkish reform movement in the 10th and 11th centuries, Richard of St Vanne in Verdon and Poppo, abbot of Stavelot (978-1048), had seen the Holy Land with their own eyes (Vita Rich. 17; Vita Popp. 3). In the year 1028 Archbishop Poppo of Trier (d. 1047) undertook a pilgrimage which led him past Jerusalem to the banks of the Euphrates, his return taking place in 1030 (Gesta Trevir. Cont. i. 4 sqq.). But the most celebrated devotional expedition before the Crusades was that of the four bishops—Sigrild of Mainz, Gunther of Bamberg, William of Utrecht, and Otto of Regensburg. They set out in 1064, with a company whose numbers exceeded seven thousand. The major portion, however, fell in battle against the Mahommedans, or succumbed to the plagues of travel. Three thousand and two thousand died on the way again (Annal. Allah., Lambh., Disth., Marion. Scot. &c.). Among the followers of the bishops were two clerics of Bamberg, Ezzo and Wille, who composed on the way the beautiful song on the miracles of Christ—one of the oldest hymns in the German language. The text was due to Ezzo, the tune to Wille (Müllenhoff and Scherer, Denkmüller, i. p. 78, No. 31). A few years later Count Dietrich of Trier began a pilgrimage to Jerusalem with 113 companions, in atonement for the murder of Archbishop Kuno. The ship, however, which conveyed them went down with all hands in a storm (Berth. Ann. 1073).

As a result of this steady increase in the number of pilgrims, the old arrangements for their accommodation were found deficient. Consequently hospices arose which were designed exclusively for the pilgrim. Those on the Alpine passes are common knowledge. The oldest, that on the Septimer pass, dates from the Carolingian period, though it was restored in 1120 by the bishop Wido of Chur; that on the Great St Bernard was founded in the 10th century, and reorganized in the 13th. To this century may also be assigned the hospice on the Simplon; to the 14th those on the St Gotthard and the Lukmanier. Similarly, the Mediterranean towns, and Jerusalem in particular, had their pilgrim-refuges. Service in the hospices was regularly performed by the hospital-fraternities—that is to say, by lay associations working under the authorization of the Church. The most important of these was the fraternity of the Hospitale hierosolymitanum, founded between 1065 and 1075; for hence arose the order of St John, the earliest of the orders of knighthood. In addition to the hospital of Jerusalem, numerous others were under its charge in Acre, Cyprus, Rhodes, Malta, &c. Associations were formed to assist pilgrims bound for the East; one being the Confrérie des péliers de Terre-Sainte in Paris, founded in 1255 by Louis de Bourbon, count of Clermont (afterwards first duke of Bourbon). Its church was in the rue des Cordeliers. Similar institutions existed also in Amsterdam, Utrecht, Antwerp and elsewhere in the Netherlands.

But since, in the middle ages, the Holy Land was no longer held by a Christian Power, the protection of the pilgrims was no less necessary than their sustenance. This fact, after the close of the 12th century, led to the Crusades (q.v.), which in many respects are to be regarded as armed pilgrimages. For the old dream of the pilgrim, to view the country where God had walked as man, lived on in the Crusades—a fact which is demonstrated by the letters of Bernard of Clairvaux, with the songs of Walther von der Vogelweide and other Crusaders. And, since the strongest motive in the pilgrimage was the acquisition of indulgences, unnumbered thousands were moved to assume the Cross, when, in 1005, Urban II. promised them plenary indulgence (Conc. Claram. c. 2). The conquest of Jerusalem, and the erection of a Christian empire in Palestine, naturally welled the influx of pilgrims. And though in 1187 the Holy City again fell into the hands of the infidel, while in 1291 the loss of Acre eliminated the last Christian possession in Palestine, the pilgrimages still proceeded. True, after the fall of the city and the loss of Acre, they were forbidden by the Church; but the veto was impracticable. In the 12th century these religious expeditions were still so common that, every Sunday, prayers were offered in church for the pilgrims (Honor. Aug. Spec. eccles. p. 838). In the 13th century the annual number of those who visited Palestine amounted to many thousands: in the 14th and 15th it had hardly shrunk. In fact, between the years 1300 and 1600, no fewer than 1400 men of distinction can be enumerated from Germany alone who travelled to the Holy Land (Röhrich and Meissner, Deutsche Pilgerreisen, pp. 465-456). It was not till the Reformation, the wars of the 16th century, and the loss of Rhodes, Candia and Cyprus to the Turks, that any appreciable alteration was effected. When Ignatius de Loyola (q.v.) set sail in 1523 from Venice to Palestine, only some thirteen soules could be mustered on the pilgrim-ship, while eight or nine others sailed with the Venetian state- vessel as far as Cyprus. A considerable number had abandoned their pilgrimage and returned home on the news of the fall of Rhodes (Dec. 25, 1522). In the 16th century Ignatius de Loyola calculated the cost of the voyage from Venice to Jaffa at some 6 or 7 gold florins (£s). The expenses of the princes and lords were, of course, much heavier. Duke William of Saxony, who was in Jerusalem in 1461, spent no less than £10,000 on his journey (see Prutz,
Great was as the number of pilgrims overseas, it was yet far exceeded by that of the visitants to the “threshold of the apostles,” i.e. Rome. As was the case with Jerusalem, guide-books to the city of the apostles were now composed. The oldest is the Notitia ecclesiast urbs Romae, which was probably compiled under Honorius I. (625–638). The monument De locis s. martyrum is of somewhat later date. Both are to be found in De Rossi, Roma sotserone, i. 138 sqq. The Itinerarium einsidlense (ed. G. Hänel, Archiv. f. Philologie, v. 119) belongs to the second half of the 8th century. Its composer would seem to have been a disciple of Walafrid; for his interests are not confined to the churches, their reliquaries, and the ecclesiastical ceremonial of saints-days, but he takes a particular interest in transcribing ancient inscriptions. William of Malmsbury, again, when relating the crusade of Count Robert of Normandy (1066), transfers into his Gesta regum anglorum (iv. § 351) an old description of Rome, originally intended for the use of pilgrims. This may have dated from the 7th century.

The pilgrimages to Rome received their greatest impetus through the inauguration of the so-called Year of Jubilee (q.v.). On the 22nd of February 1300 the bull of Boniface VIII, Antiquorum habit fidem, promised plenary indulgence to every Roman who should visit the churches of the apostles Peter and Paul on thirty days during the year, and to every foreigner who should perform the same act on fifteen days. At the close of the Jubilee this dispensation was extended to all who had expired on the way to Rome. This placed the pilgrimage to Rome on a level with the crusades—the only mode of obtaining a plenary indulgence. The success of the papal bull was indescribable. It is computed that, in the Year of Jubilee, on an average, 200,000 strangers were present in the city during the day. The greatest number of the pilgrims came from southern France, England sending comparatively few on that occasion (see Gregorovius, Gesch. d. Stadt Rom. v. 546 sqq.). The Jubilee dispensation according to the edict of Boniface VIII. was to be repeated every century; but this period was greatly abridged by succeeding popes (see JUBILEE, YEAR 09), so that in the years 1310, 1350, 1423, 1450, 1475, 1500, the troops of pilgrims again came streaming into Rome to obtain the cherished dispensation.

Of the other pilgrim-resorts, we shall only emphasize the most important. Priority of mention is due to St James of Compostella (Santiago, in the Spanish province of Galicia). Here the attraction for the pilgrim was the supposed possession of the body of James the son of Zebedee. The apostle was executed (A.D. 44) by command of Herod Agrippa (Acts xii. 1); and at the beginning of the medieval period it was believed that his corpse was laid in Palestine (Venant. Fortun. Cantor. v. 144, viii. 3). The first connexion of the apostle with Spain is to be traced in the Poesia de aris b. Mar. et xii. apost. dedici, which is ascribed to Aldhelm (d. 700) and contains a story of his preaching in that country. The earliest account of the transference of his relics to the Peninsula is found in Notker Balbulus (d. 912, Martyr. in Jul. xxc.). But in Spain belief in this cherished possession was universal; and, step by step, the theory won credence throughout the West. In 1090, Archbishop Wido of Milan journeyed to St James (Damiani, Acta med. p. 68); and a little later we hear of bands of pilgrims from Germany and France. In England, indeed, the shrine of St James of Compostella became practically the most favoured devotional resort; and in the 12th century its visitation had attained such popularity that a pilgrimage thither was ranked on a level with one to Rome or Jerusalem (Honor. August. Spec. eccl. p. 828). In Paris, after 1149, there existed a special hospice for the “fraternity of St James,” in which from 60 to 80 pilgrims were received each day, fed, and presented with a quarter of a denarius (Dulaure, Hist. de Paris (1842), i. 531). Even in the period of the Reformations the “Song of St James” was sung in Germany (Wackernagel, Kirchenlied, ii. No. 1246); and in 1478 pilgrimages to that shrine were placed by Sixtus IV. on official equality with those to Rome and Jerusalem (Extrav. comm. c. 5; De poenit. v. 9).

In France St Martin remained the chief goal of the pilgrimage; while Notre Dame de Sous-Terre in Chartres (with a portrait of the “black Virgin”), Le Puy-en-Velay (dep. Haute Loire), and others, also enjoyed considerable celebrity. In England pilgrimages were made to the tomb of the murdered archbishop, Thomas Becket, in Canterbury Cathedral. The setting of Chaucer’s Canterbury Tales gives a vivid idea of the motley company of pilgrims; but it seems probable that Germany also sent a contingent (Gervas. Cantu. cl. ann. 1184; Ralph de Ricci, F. mag. hist. ann. 1184). In addition, Walsingham, Peterborough, St Davids, Holywell, and St Andrews in Scotland were much frequented. In lower Germany, Cologne and Aix-la-Chapelle, in Switzerland Einsiedeln, were the principal resorts.

In Italy the church of the Archangel on Mt Gargano was one of the most ancient centres of the pilgrimage, being visited even by the monk Bernard (vide supra). Later the Portinuncula church at Assisi displaced all other religious resorts, with the exception of Rome; but in the 15th century it was overshadowed in turn by the “Holy House” at Loreto on the Adriatic. According to an extraneous report, the house of Joseph and Mary in Nazareth was transported by angels, on the night of the 9th–10th of May 1291 to Dalmatia, then brought to the Italian coast opposite (Dec. 10, 1294), till, on the 7th of September 1295 it found rest on its present site. The pilgrimage thither must have attained great importance as early as the 15th century; for the popes of the Renaissance found themselves constrained to erect an imposing pilgrim church above the “Holy House.”

The significance of the pilgrimage for the religious life of later medievalism cannot be adequately estimated. The possession of an extraordinary relic, a bloody Host, or the like, was everywhere considered a sufficient claim for the privileges of indulgences; and wherever this privilege existed, there the pilgrims were gathered together. All these pilgrimages, great and small, were approved and encouraged by the Church. And yet during the whole of the middle ages, the voice of suspicion in their regard was never entirely stilled. Earnest men could not disguise from themselves the moral dangers almost inevitably consequent upon them; they recognized, moreover, that many pilgrims were actuated by extremely dubious motives; and they distrusted the exaggerated value set on outward works. The Roman papacy had no more zealous adherent than Boniface; yet he absolutely rejected the idea that Englishwomen should make the journey to Rome, and would willingly have seen the princes and bishops veto these pilgrimages altogether (Ep. 78). The theologians who surrounded Charlemagne held similar views. When the abbess Ethelburga of Flambury (Worcester) found her people engaged in the pilgrimage impracticable, Alcuin wrote to her, saying that it was a great loss, and that he and better judges for her: “Expend the sum thou hast gathered for the journey on the support of the poor; and if thou givest as thou canst, thou shalt reap as thou wilt” (Ep. 300). Bishop Theodulf of Orleans (d. 821) made an energetic protest against the delusion that to go to Rome availed more than to live an upright life (Carm. 67). To the same effect, the synod of Chalon-sur-Saône (813) reproved the superstition which was wedded to the pilgrimage (c. 13); and it would be easy to collect similar judgments, delivered in every centre of medievalism. But, fundamentally, pilgrimages in themselves were rejected by a mere handful: the protest was not against the thing, but against its excrescences. Thus Fridank, for instance, in spite of his emphatic declaration that most pilgrims returned worse than they went, himself participated in the crusade of Frederick II.

V. The Modern Pilgrim.

The Holy House has perpetuated the belief in the religious value of visits to a particular locality. It is only pious memory that draws the Protestant to the sites consecrated by ecclesiastical history. On the other hand, while in the Eastern Church things have undergone little change,—the pilgrims, in addition to the Holy Land, visiting Mt Athos and Kiev—the developments in the Roman Church show important divergences. The Year of Jubilee, in 1525, was unprecedented in its scant attendance, but the jubilees of 1575 and 1600 again saw great armies of pilgrims marching to Rome.
PILIBHIT—PILLORY

Fresh pilgrim resorts now began to spring up, and medieval shrines, which had fallen on evil days, to emerge from their obscurity. In the 16th century we must mention the pilgrimage to the "Holy Mount" at Góra on the Austrian coast, and to Montserrat in the Spanish province of Barcelona; in the 17th century, those to Luxemburg, Kevelaer (Gelderland), Notre Dame de Fourvière in Lyons, Héligében in Bohemia, Roermond in the Netherlands, &c. The 18th century, which witnessed the religious Aufklärung, was not favourable to the pilgrimage. Enlightened bishops and princes prohibited it altogether: so, for instance, Joseph II. of Austria. Archbishop Clement Wenceslaus of Trier forbade, in 1777, the much-frequented, medieval "leaping-procession" of Echternach (duchy of Luxemburg). The progressive theologians and clergy, moreover, assumed a hostile attitude, and, in 1800, even the Curia omitted the Year of Jubilee. The 19th century, on the other hand, led to an extraordinary revival of the pilgrimage. Not only did new resorts spring into existence—e.g. La Salette in Dauphiné (1846)—and more particularly Lourdes (1868) in the department of Hautes Pyrénées—but the numbers once more attained a height which enables them to compete with the medieval figures. It is computed that 60,000 pilgrims were present in La Salette on the 29th of September 1847, the first anniversary of the appearance of Mary which gave rise to the shrine. The dedication of the church of Lourdes, in 1876, took place in the presence of 30 bishops, 3000 priests and 100,000 pilgrims. In 1877 the number rose to 250,000; and similar statistics are given of the German and Austrian devotional resorts. The sanctuaries of Aix-la-Chapelle are said to have been visited by 65,000 pilgrims on the 15th of July 1860; and on the following Sunday by 52,000. From 25,000 to 30,000 persons take part each year in the resuscitated "leaping-procession" at Echternach; and the annual visitants to the "Holy Mount" at Góra are estimated at 30,000. No new motives for the pilgrimage emerged in the 19th century, unless the ever-increasing cultus of the Virgin Mary may be classed as such. Besides, the new devotional sites being dedicated to the Virgin. For the rest, the desire of acquiring indulgences maintains its influence: but doubtless voices are no more heard within the pale of the Roman Catholic Church.

(A. H.*

PILIBHIT, a town and district of British India, in the Bareilly division of the United Provinces. The town—pop. (1901), 33,492—contains the nucleus of Haib-Khan, the Rohillah chieftain, built in the second half of the 18th century. Trade is mainly in agricultural produce, and in the products of the neighbouring Himalayan territory and Nepal.

The District of Pilibhit has an area of 1330 sq. m.; pop. (1901), 470,339, showing a decrease of 3% in the decade. Though so near the Himalayas it is entirely a plain. In its midst is the Mala swamp. The east is forest-clad, poor and unhealthy; on the other side of the Mala the land becomes more fertile. The chief river is the Sarda, and the Gumti rises in the east. The principal crops are rice, pulses, wheat and sugar-cane. Sugar-refining is carried on, and sugar, wheat, rice and hemp are exported. The Lucknow-Bareilly section of the Oudh & Rohilkhand railway runs through the district, a portion of which is worked by the Rohilkhand canals.

PILLAR (O. Fr. piler, Mod. pilier, Late Lat. pilare, from pila, column), an isolated upright structure, of narrow width in relation to its height, which is either employed as a support for a superincumbent load of some sort or is set up for commemorative or ornamental purposes. In the first sense the word has many common applications, as to columns supporting the girders of a warehouse floor or the deckbeams of a ship, to the single central support or pedestal of a table, machine-1001, &c., and to the masses of metal which the shipwright may arrive at certain methods of working as supports to the roof (see Coal); it is also used figuratively of persons in such phrases as a "pillar of the state." In architecture it has strictly the second sense. The column erected in honour of Diocletian at Alexandria is known as Pompey's pillar, and the so-called columns of Trajan and Antoninus are in reality pillars, performing no structural function beyond that of carrying a statue. In India the only example is the iron pillar at Delhi, which is an extraordinary specimen of the iron-worker's art considering the remote date at which it was made. Up to the middle of the 10th century the term "pillar" was employed to designate the masses of masonry in a church, which carry the arcades, but now the term "pier" is invariably adopted in preference.

PILLAU, a seaport and watering-place of Germany, in the Prussian province of East Prussia, on the spit of sand (Nehrung) which separates the Frische Haff from the Baltic, on the north of the entrance channel, and 20 m. by rail from Königsberg. Pop. (1903), 7374. It is fortified and has a harbour, which serves as the outer port of Königsberg, and to some extent also of Elbing and Braunsberg. A new navigable channel was in 1900—1901 constructed across the Frische Haff from Pillau to Königsberg. Pillau has a school of navigation, and is a well-known pilot station. Ship-building, sail-making, fishing and the working of amber are carried on.

Pillau is memorable as the place where Gustavus Adolphus of Sweden landed in 1626. It did not obtain civic privileges until 1725, but was fortified shortly after that date. In 1807 it offered a stout resistance to the French. By a treaty of the 24th of February 1812 it was ceded to Napoleon, but on the 6th of February in the following year it was restored to Prussia.

PILLION, a light saddle without pommel or bow, especially a pad fastened to the back of an ordinary saddle, as a seat for another person, generally a woman. Pillows were also used to support baggage. They were in common use from the 16th to the 18th centuries. The word appears to have been adapted into English from the Irish pillín, cushion, formed from Lat. piléus, skin. In the sense of a hat worn by a priest or doctor of divinity, "piller" or "pyllon" occurs in the 15th and 16th centuries. This is probably from Lat. piléus, a conical felt hat or cap, Gr. πιλέος.

PILLNITZ, a village in the kingdom of Saxony, situated on the right bank of the Elbe, 5 m. above Dresden. Pop. (1903), 770. The new palace of the king of Saxony was built in 1818 on the site of a building which was destroyed by fire. The place became a residence of the electors of Saxony about 1300, and the different parts of the palace were erected at various times during the 18th century. By the convention of Pillnitz in August 1791 the emperor Leopold II. and Frederick William II., king of Prussia, agreed to take common action against any attack on the part of Napoleon, and may be regarded as the basis of the first coalition against that country. See A. von Minchitz, Geschichte von Pillnitz (Dresden, 1893).

PILLORY (O. Fr. pilori, Prov. espilori, from Lat. spectulorum, a place of observation or "peep-hole"), an instrument of punishment which consisted of a wooden post and frame fixed on a platform raised several feet from the ground, behind which the culprit stood, his head and his hands being thrust through holes in the frame (as are the feet in the stocks) so as to be held fast, exposed in front of it. This frame in the more complicated forms of the instrument consisted of a perforated iron circle, which secured the heads and hands of several persons at the same time, but it was commonly capable of holding only one. In the statutes of Edward I. it is enacted that every pillory or "stretch-neck" should be made of convenient strength so that execution might be done on offenders without peril of their bodies. It was customary to shave the heads wholly or partially, and the beards of men, and to cut off the hair and even in extreme cases to shave the heads of female culprits. Some of the offences punished in England by the pillory will be found enumerated in
a statute of Henry III. (1266). By this “Statute of the Pillory” it was ordered as the penalty for “forestallers and regrators, users of deceitful ways, perjurers and forgers,” Stow, describing Cornhill pillory, says: “On the top of the cage (a strong prison of timber) was placed a pillory for the punishment of bakers offending in the assize of bread, for millers stealing corn at the mill, for bawds, scolds and other offenders.” Until 1637 the pillory was reserved for such offenders. In that year an attack was made on the Press, and the pillory became the recognized punishment of those who published books without a licence or libelled the government. Alexander Leighton, John Lilburn, Prynne and Daniel Defoe were among those who suffered. These were popular favourites, and their exposures in the pillory were converted into public triumphs. Titus Oates, however, was put in the pillory in 1685 and nearly killed. In 1816 the pillory was abolished except for perjury and subornation, and the perjurer Peter James Boscy was the last to stand in the pillory at the Old Bailey for one hour on the 22nd of June 1839. It was finally abolished in 1837 at the behest of William IV’s reign. In France the pillory, called carcan, was employed till 1820. In Germany it was known as pranger. The pillory was used in the American colonies, and provisions as to its infliction existed in the United States statute books until 1839; it survived in the state of Delaware until 1905.

Finger-pillories were at one time in common use as instruments of domestic punishment. Two stout pieces of oak, the top being hinged to the bottom or fixed piece, formed when closed a number of holes sufficiently deep to admit the finger to the second joint, holding the hand imprisoned. A finger-pillory is preserved in the parish church of Ashby-de-la-Zouch, Leicestershire, and there is one, still in its original situation against the wall, at Littlecote Hall, Wilts.

**Pillow**—**Pillow**

**Pillow** (O. Eng. *pylus*; Lat. *pulvinus*, a cushion), a support for the head during sleep or rest. The pillow of Western nations is a cushion of linen or other material, stuffed with feathers, down, hair or wool. In the East it is a framework made of bamboo or rattan with a depression in the top to receive the neck; similarly blocks of wood with a concave-shaped top are used by the natives of other countries. The word is found in various technical uses for a block or support, as for a brass bearing for the journal of a shaft, and the like. In architecture the term “pillowed,” or “pulvinated,” is given to the frieze of an order which bulges out in the centre and is convex in section. It is found in friezes of some of the later works of the Roman school and is common in Italian practice.

**Pilocarpine**, CH$_3$H$_8$N$_2$O$_4$, an alkaloid found, together with isopilocarpine and other related compounds, in the leaves of *jaborandi* (*Pilocarpus jaborandi*). It was first isolated by E. Hardy in 1873 (Ber. 8, p. 1594), and is a crystalline, very hygroscopic solid. It is a strong poison. It has the properties of a monacid base and contains the methylamino group, -NCH$_3$.

When heated with hydrochloric acid it gives isopilocarpine. Isopilocarpine was isolated by I. J. S. Jowett (Journ. of Chem. Soc. 72, p. 174), and is a colourless oil which boils at 26$^\circ$ C. (10 mm.). It is a monacid base which is readily soluble in solutions of the caustic alkalis. Jowett is of the opinion that pilocarpine and isopilocarpine are stereo-isomers of the structure:

$$\text{CH}_3\text{N}^-\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}^- \quad \text{CH}_2\text{CH}^-\text{CH}_2\text{CH}_2$$

**Pilona**, a town of northern Spain, in the province of Oviedo; between the right bank of the river Pilona, a left-hand tributary of the Sella, and the Sierra de Abes (3268 ft.). Pop. (1900), 18,228. Though officially classed as a town, Pilona is rather a densely populated mining and agricultural district. It is served by the railway from Infiesto, on the river Pilona, to Oviedo and Gijon.

**Pilot**, the name applied either to a particular officer serving on board a ship during the course of a voyage and having the charge of the helm and the ship’s route, or to a person taken on board at a particular place for the purpose of conducting a ship through a river, road or channel, or from or into a port. The latter kind is the only one to which the term is now applied either in British or foreign countries. The word “pilot” is not the early name for the man who guides or steers a ship. In Old English the name is *lādman*, i.e., the man who leads the way. “Pilot” does not appear in English till the 16th century. The origin of the word has been much debated. Many etymologists find it in the Dutch *piloot* (Hexham’s Dictionary, 1638). This has been identified with *peillood*, *peil-loth*, sounding lead, cf. German *peilen*, to sound; the last part of these words is the same as English “lead,” the metal; the first part, *peilen*, is for *pelegen*, to mark with pegs or points for measuring, cf. *pegel*, gauge. The *New English Dictionary*, on the other hand, finds that the Dutch *piloot*, the earlier form, is taken from the French. The source is, therefore, to be looked for in Romance languages. Du Cange (Gloss. Med. et Inf. Lat.) gives Pedotae, defined as *quorum est scire intrane in extere portus*; a gloss on *pedote et timonieri* in F. Ubaldini’s edition, 1640, of *I documenti d’amore* by Francesco da Barberino (1264-1348). It is therefore conjectured that the Italian *pilota* is a popular conception of *pedota*, and a possible source may be found in the Greek *pílhos*, ear.

In England, formerly, pilots were subject to the jurisdiction of the lord high admiral; and in the 16th century there are many instances of the admiralty court dealing with pilots disciplinarily as well as civilly, holding them liable in damages to owners of ships lost or damaged by their negligence. For some considerable time throughout the United Kingdom the appointment and control of pilots have been in the hands of numerous societies or corporations established at the various ports by charter or act of Parliament, such as the Trinity Houses of Deptford Strond (London), Kingston-upon-Hull, Newcastle-on-Tyne, and Leith, and the Society of Cinque Ports Pilots and Court of Lodemange (now extinct). These societies had jurisdiction over the pilots exercising their employment within the limits of such ports, and in many cases made it compulsory for ships resorting thither to employ them. By degrees the London Trinity House acquired a leading position, which was confirmed and extended by the general Pilotage Acts passed in the 18th and 19th centuries, with the object of introducing a uniform system throughout the realm. At the present day the United Kingdom is divided into districts for the purpose of pilotage jurisdiction. The (London) Trinity House has jurisdiction over the London district, which extends from Orfordness to Dungeness, and comprises the Thames and Medway up to London and Rochester bridges; the English Channel district, comprising the sea between Dungeness and the Isle of Wight, and the Trinity port district, which includes any other pilotage districts for the appointment of pilots within which no particular provision is made by act of Parliament or charter, and the number of which is 40, all English and Welsh. There are 66 other districts, within which other pilotage authorities have jurisdiction.

The present general pilotage law is contained in the Merchant Shipping Acts 1894 to 1906. Pilotage authorities are defined as bodies or persons authorized to appoint or license pilots, or to fix and alter rates of pilotage or to exercise any jurisdiction in respect of pilotage. They are subject to the control of the Board of Trade as the supreme mercantile marine authority. Those bodies, however, which existed at the time of the passing of the act retain their powers and jurisdiction, so far as is consistent with it. The board has power to appoint a new pilotage authority in any area where there is none, and to include a new area where there is none within an already existing one (but in either case pilotage cannot be made compulsory), or to transfer pilotage jurisdiction over a port other than that where the pilotage authority for that port resides, from that pilotage authority to the harbour or other local authority for that port, or to the Trinity House, or to a new authority; and the board has all powers necessary to effectuate such transfer and the new authority. The board may also, by provisional order (which requires parliamentary confirmation), provide for the representation of pilots or shipowners on the pilotage authority
of any district, and the exemption of ships from compulsory pilotage in any district. Where pilotage is not compulsory, the power of obtaining pilotage licences unrestricted, the board can in the same way, give the pilotage authority powers with respect to licences, amount of pilotage rates, and the like. Pilotage authorities may, by by-laws under the act (which require confirmation by order in council), exempt wholly or partly any ships or classes of ships from compulsory pilotage, and regulate the means of obtaining licences, and the amount of pilotage rates, subject to a maximum limit. They must make yearly returns to the Board of Trade of their by-laws, the names, ages and services of their licensed pilots, the rates of pilotage, the amounts received for pilotage and their receipts and expenditure; and if they fail to do so, the board may suspend their authority, which is then exercised by the Trinity House.

The statutes also provide generally for the qualifications of pilots. A “qualified” pilot is one duly licensed by a pilotage authority to conduct ships to which he does not belong.

Qualifications.

On his appointment he receives a licence, which is registered with the chief officer of customs at the nearest place to the pilot’s residence, and must be delivered up by the pilot whenever required by the licensing pilotage authority. On his death this licence must be returned to that authority. By an act of 1906 no pilotage certificate shall be granted to the master or mate of a British ship unless he is a British subject; this does not, however, refer to the renewal of a certificate granted before 1906 to one not a British subject. Pilotage dues are recoverable summarily from the owner, master, or consignee of the ship, after a written demand for them has been made. A pilot may not be taken beyond the limits of his district without his consent, and if so taken he is entitled to a fixed daily sum in addition to the dues; if he cannot board the ship, and leads her from his boat, he is entitled to the same dues as if he were on board; and he must be truly informed of the ship’s draught of water. An unqualified pilot may in any pilotage district take charge of a ship without subjecting himself or his employer to any penalty, where no qualified pilot has offered himself, where a ship is in distress, or in circumstances where the master must take the best assistance he can, or for the purpose of changing the commodore of any ship in port on docking or undocking her; but after a qualified pilot has offered himself any unqualified pilot continuing in charge, or any master continuing him in charge of the ship, is liable to a penalty. A qualified pilot may not be directly or indirectly interested in licensed premises or in the selling of dutiable goods, or in the unnecessary supply of gear or stores to a ship for his personal gain or for the gain of any other person. He can be punished for quitting a ship before the completion of his duty without the consent of the master, refusing or delaying to perform his duty without reasonable cause when required by lawful authority, lending his licence, acting as pilot when suspended or when intoxicated, and any pilot who through wilful breach of or neglect of duty, or by reason of his drunkenness, endangers ship, life or limb, is guilty of a misdemeanour and liable to suspension or dismissal; but the pilot has an appeal in cases of fines over £1, of suspension or dismissal, suspension or revocation of his licence, or the assessment of a pilotage fund to which he has contributed. This appeal lies in England to a county court judge having jurisdiction over the port where he is licensed, or a metropolitan police magistrate or stipendiary magistrate with the like power; in Scotland, to a sheriff; in Ireland, to a county court judge, chairman of quarter sessions, recorder, or magistrate. Pilotage certificates may also be granted by pilotage authorities, available within their districts, to masters and mates of ships; and the holder of such a certificate may pilot any ship in respect of which it is available without incurring any penalty for not employing a qualified pilot.

The statute further makes special regulation for Trinity House pilots. Every such pilot, on his appointment, must execute a bond for £100 conditioned for due observance of the Trinity House regulations and by-laws, and thereupon he is not liable for neglect or want of skill to anybody beyond the penalty of the bond and the amount payable to him for pilotage on the voyage on which he engaged at the time of his so becoming liable. The licence may be revoked or suspended by the Trinity House when it thinks fit; it only continues in force for a year, and the Trinity House has absolute discretion whether it shall be renewed or not.

A pilot boat is approved and licensed by the district pilotage authority who appoints or removes the master thereof. In order to be easily recognized, she has printed on her stern in legible white letters the name of her owner and port, and on her bows the number of her licence; the remainder of the boat is usually black. The pilot flag is a red and white horizontal flag of a comparatively large size, and is flown from a conspicuous position. When the flag is flown from a merchant vessel, it indicates that a licensed pilot is on board or that the master or mate holds a certificate entitling him to pilot the ship. By order in council of 1900, on and after the 1st day of January 1901, the signals for a pilot displayed together or separately are: In daytime, there is (1) hoisted at the fore the pilot jack (Union Jack having round it a white border, one-fifth of the breadth of the flag); (2) the international code pilotage signal indicated by P.T.; (3) the international code flag S. (white with small blue square centre), with or without the code pennant; (4) the distant signal consisting of a cone point upwards, having above it two balls or shapes resembling bulls. By night, (1) the pyrotechnic light commonly known as a blue light, every fifteen seconds; (2) a bright white light, flashed or shown at short or frequent intervals just above the bulwarks, for about a minute at a time.

Pilotage in British waters may be either compulsory or free for all or certain classes of ships. From parliamentary pilotage returns, it appears that it is compulsory in about 64 districts of the United Kingdom (of which two thirds are the Trinity House districts), free in 32, free and compulsory in 8, while in 3 cases (Berwick, Dingwall and Coleraine) no particulars are given. British war-ships in British waters are not compelled to employ a pilot, the navigating officer becoming the pilot under the direction of the captain. If a pilot be employed, the captain and navigating officer are not relieved from responsibility. They supervise the pilot, and should, if necessary, remove him from the ship. In the majority of foreign ports British war-ships are exempted from employing pilots, but the Suez Canal and the ports of France are exceptions. The Merchant Shipping Act 1894 continues the compulsory employment of pilots in all districts where it was already compulsory, and also the already existing exemptions; and there is no power in any pilotage authority or the Board of Trade to increase the area of compulsory pilotage, though there is to diminish it. Compulsion is enforced by a provision in the act, that within a district where compulsory pilotage exists, the master of an unexempted ship who pilots her himself without holding the necessary certificate, after a qualified pilot has offered or signalled to take charge of the ship, shall be liable for each offence to a fine of double the amount of the pilotage dues payable for the conduct of the ship. The exceptions from compulsory pilotage still existing in British territorial waters are as follows: Ships or vessels with British registers trading to Norway or the Cattegat or the Baltic (except vessels on voyages between any port in Sweden or Norway and the port of London), or round the North Cape, or into the White Sea on their inward or outward voyages, whether coming up by North or South Channels; any constant British traders inwards from ports between Boulogne inclusive and the Baltic coming up by North Channel, and any British ships or vessels trading to ports between the same limits on their outward passages and when coming up by the South Channels; Irish traders using the navigation of the Thames and Medway; ships engaged in the regular coasting trade of the kingdom; ships or vessels wholly laden with stone produced in the Channel Islands and Isle of Man and brought thence; ships or vessels not exceeding 60 tons, whether British or belonging to a foreign country specified by order in council; ships within the limits of the port or place to which they belong, if
of a compulsory pilot has been much criticized in recent times, and it would seem that the foreign view is much more satisfactory in regarding the pilot merely as the adviser and not the superior of the master. Moreover, the adoption of the foreign law on this point would restore the old general maritime law. The policy of the law was at one time inclined to extend this principle of compulsory pilotage, on the ground that it was for the benefit of commerce and the safety of seamen’s lives, but it now restricts it within as narrow limits as possible, e.g., the presence of a compulsory pilot on board a tow who is directing the navigation of a tug does not protect the tug-owner from liability for negligent navigation. As already pointed out, pilotage authorities have no power to extend its scope.

A pilot is generally considered in charge of a ship under English law if he has supreme control over her navigation, superseding the master for the time being; and if she is a tow he has also control of the navigation of her tug. The judicial decisions establish that it is within his province to decide whether the ship shall get under way, the proper time and place for her to anchor, the way of carrying her anchor, the proper orders for the helm, her rate of speed, and whether the statutory rules of navigation shall be complied with; and the master and crew must not interfere with his control, and only remain liable for the proper execution of the pilot’s orders and the trim and general efficiency as to look-out, &c., of the ship. The master, however, is bound to supersede the pilot in case of his intoxication or manifest incapacity, and to interfere if there is a clear and plain prospect of danger to the ship in following the pilot’s directions, e.g., getting under way in a thick fog. The pilot is entitled to receive from the master assistance in having his attention called to anything which a competent mariner would see that ought to be known. A pilot taken voluntarily, and not by compulsion of law, is considered as the servant of the shipowner, and as such renders him liable for his acts of negligence towards third parties. He does not, it seems, supersede the master in the control of the ship, but only advises him. The Admiralty and the Board of Trade and the Trinity House all take the view that the captain or master is bound to keep a vigilant eye on the navigation of the vessel by the pilot, and insist on all proper precautions being taken.

For the purposes of a policy of marine insurance a ship is not seaworthy without a pilot in compulsory pilotage waters; and where there is no legal compulsion to have one, but the locality requires navigation by a person having local knowledge, it has been said that a ship must take a pilot, certainly when leaving a port, and probably on entering a port if a pilot is available.

A pilot can sue for his pilotage fee at common law or in Admiralty (q.v.), in the latter case provided that the contract was made and the work done not within the body of a county; but he has a summary remedy by statute which is of easier application. He cannot be sued in Admiralty for damage done by a collision caused by his negligence (e.g., on the Admiralty side of a county court having Admiralty jurisdiction); but he can be made liable at common law or in the Admiralty Division of the High Court, although in the case of a Trinity House pilot his liability is limited to the amount of the bond and pilotage fee then being earned (see above); but the court has refused to join him as a defendant to an action in rem brought against the ship of which he had the charge. A pilotage authority cannot be made liable for the negligent navigation of a ship by a pilot which it has licensed, for he is not its servant, though it has been held liable for the negligence of a person not licensed by it as a pilot, but employed by it for wages to pilot ships into a harbour under its jurisdiction, itself taking the pilotage dues and applying them for harbour purposes. A pilot is not in common employment with the master and crew of a ship, and can recover for any injury done him by their negligence. He may be entitled to claim salvage from a ship of which he has charge, if the services were rendered before the loss occurred, if he can establish that the ship was not seaworthy at the time of loss, or that the loss was occasioned by his negligence. (See SALVAGE.)

In the United States pilotage laws are regulated by the respective
states. If the waters are the boundary between two states a duly licensed pilot of either state may be employed, but no discrimination can be made in the rates of piloting between vessels of different states. In the German Empire the piloting laws are very complicated. In the majority of the maritime states each one has its own regulations and laws. In Prussia there is a government pilots who enter the service as apprentices, and are placed under a department of state. In France the general organization of pilots is regulated by the Statute on Pilots of the 12th of December 1866, and the piloting regulations for each port are made by the minister of marine at the request of his local representative and the Chamber of Commerce. French pilots are exempt from military service.

PILOT-FISH (Naucrates ductor), a pelagic fish of the family of horse-mackerels or Carangidae, well known to sailors from its peculiar habit of keeping company with ships and large fishes, especially sharks. It occurs in all tropical and sub-tropical seas, and is common in the Mediterranean, but becomes scarcer in higher latitudes. In summer pilots will accompany ships as far north as the south coast of England into port. This habit was known to the ancients, who describe the Pomphus as a bird which points out the way to dubious or embarrassed sailors, and by its sudden disappearance indicates to them the vicinity of land; the ancient seamen of the Mediterranean regarded it, therefore, as a sacred fish. That the pilot accompanies sharks is an observation which first appears in works of travel of the 17th century, the writers asserting that it is of great use to its big companion in conducting it and showing it the way to its food. It is, however, extremely doubtful whether the pilot's connexion with a shark serves a more special purpose than its temporary attachment to a ship. It accompanies both on account of the supply of food which it derives from them. The pilot, therefore, stands both in the relation of a so-called "commissal," like the Echeneis or suckling-fish. All observers, however, agree that neither the pilot nor the sucker is ever attacked by the shark. The pilot attains to a length of about 12 in. In the shape of its body it resembles a mackerel, but is rather shorter, especially in the head, and covered with small scales. A sharp keel runs along the middle of each side of the tail. The first dorsal fin consists of a few short spines not connected by a membrane; the second dorsal and the anal are composed of numerous rays. The teeth, which occupy the jaws, vomer and palatine bones, are all small, in villiform bands. The coloration of the pilot renders it conspicuous at a distance; on a bluish ground-colour from five to seven dark-blue or violet cross-bands traverse the body from the back to the belly. The pilot-fish spawns in the open sea, and its fry is constantly caught in the tow-net. But young pilot-fish differ considerably from the adult, having the spines of the first dorsal connected by a membrane, and some bones of the head armed with projecting spines. These little fishes were therefore long considered to be a distinct genus, Naucerus.

PILOTY, KARL VON (1826-1886), German painter, was born at Munich, on the 1st of October 1826. His father, Ferdinand Piloty (d. 1844), enjoyed a great reputation as a lithographer. In 1840 he was admitted as a student of the Munich Academy, under the artists Schorn and Schnorr. After a journey to Belgium, France and England, he commenced work as a painter of genre pictures, and in 1853 produced a work, Die Amme ("The Wet Nurse"), which, on account of its originality of style, caused a considerable sensation in Germany at the time. But he soon forsaw this branch of painting in favour of historical subjects, and produced in 1854 for King Maximilian II. "The Adhesion of Maximilian I. to the Catholic League in 1609." It was succeeded by "Seni at the Dead Body of Wallenstein" (1855), which gained for the young painter the membership of the Munich Academy, where he succeeded Schorn (his brother-in-law) as professor. Among other well-known works by Piloty are the "Battle of the White Mountain near Prague," "Nero Dancing upon the Ruins of Rome" (1861), "Godfrey of Bouillon on a Pilgrimage to the Holy Land" (1861), "Galleco in Prison" (1864), and "The Death of Alexander the Great" (unfinished), his last great work. He also executed a number of mural paintings for the royal palace in Munich. For Baron von Schach he painted the justly celebrated "Discovery of America." In 1874 he was appointed keeper of the Munich Academy, being afterwards ennobled by the king of Bavaria. Piloty was the foremost representative of the realistic school in Germany. He was a most successful teacher, and among his more famous pupils may be mentioned Makart, Lenbach, Defregger, Max and Grützner. He died at Munich on the 21st of July 1886.

PILSEN (Czech, Plzen), a town of Bohemia, Austria, 68 m. W.S.W. of Prague by rail. Pop. (1900), 68,292, of which 94% are Czech. It is the second town of Bohemia, and lies at the confluence of the Radbuza and the Mies. It consists of the town proper, which is regularly built and surrounded with promenades on the site of the old ramparts, and of three suburbs. The most prominent buildings are the Gothic church of St. Bartholomew, said to date from 1292, whose tower (325 ft.) is the highest in Bohemia, and the fine Renaissance town hall dating from the 16th century. The staple article of manufacture and commerce is beer, which is exported to all parts of the world. Other industrial products are machinery, enamelled tineware, leather, alum, paper, earthenware, stones and spirits, while a tolerably brisk trade is carried on in wool, feathers, cattle and horses. In the neighbourhood are several coal-pits, iron-works and glass-works, as well as large deposits of kaolin.

Pilsen first appears in history in 796, as the scene of a battle in the war between Prince Boleslaus and the emperor Otto II., and it became a town in 1272. During the Hussite wars it was the centre of Catholic resistance to the Hussites; it was three times unsuccessfully besieged by Prokop the Great, and it took part in the league of the Romanist lords against King George of Podebrad. During the Thirty Years' War the town was taken by Mansfield in 1618 and not recaptured by the Imperialists till 1621. Wallenstein made it his winter-quarters in 1633, and it was in the great hall of the Rathaus that his generals took the oath of fidelity to him (January 1634). The town was unsuccessfully besieged by the Swedes in 1637 and 1648. The first Bohemian printing press was established here in 1468.

PIMA, a tribe and stock of North American Indians. Their range was southern Arizona and northern Mexico. The ruined Pima village, known to the Spanish as Casa Grande on the south bank of the Gila, is an example of their early civilization and skill in building. Driven out of their homes by neighbouring tribes, they lived a more or less nomadic life. They were always good farmers, showing much skill in irrigation. At first submitting to the Spaniards, they revolted in 1751, destroying all the missions. The war lasted two years, but since then the Pima Indians have been friendly with the settlers. As a race they are brave, honest and hard working. They number some 5000 on two reservations in Arizona. The Piman stock includes such tribes as the Apacho, Huichol, Opata, Tarumari, and numbers up to 13,000 of a highly civilized people.

PIMENTO, also called allspice (from a supposed combination of various flavours) and Jamaica pepper, the dried immature fruit of Eugenia pimenta or Pimenta officinalis, an evergreen tree about 30 ft. high, belonging to the natural order Myrtaceae. It is indigenous in the West India Islands, growing on limestone hills near the sea, and is especially grown in Jamaica. The spice derives its name from the Portuguese pimenta, Spanish pimienta, pepper, which was given to it from its resemblance to...
The broken ink of a limpet is a spice. The oil, the action of which resembles that of cloves, is occasionally used in medicine, and is also employed in perfuming soaps. The "bay rum" used as a toilet article is a tincture scented with the oil of the leaves of an allied species, *Pimenta acris*, commonly known as the bayberry tree.

**PIN (a doublet with "pin")** from Lat. *pinna*, feather, pinnacle, (which is said to contain the same root as *pirus*, pine tree, and properly to mean a sharp point or end), a small peg or bolt of metal or wood, not necessarily pointed, employed as a fastening to connect different parts of an article, as a stop to limit the motion of some moving piece in a machine, as a support on which a small wheel may turn, &c., but most commonly a small metal spike, used for fastening portions of fabrics together, having one end pointed and at the other a bulbéd head, or some other arrangement for preventing the spike from passing entirely through the cloth or other material with which it is employed. In one form or another pins of this last kind are of the highest antiquity. They were inserted in the thorn. Pins of bronze, and bronze brooches in which the pin is the essential feature, are of common occurrence among the remains of the bronze age. The ordinary domestic pin had become in the 15th century an article of sufficient importance in England to warrant legislative notice, as in 1483 the importation of pins was prohibited by statute. In 1440 Queen Catherine received pins from France, and again in 1543 an act was passed providing that "no person shall put to sale any pinnes but only such as shall be double head, and have the heads soleder fast to the shank of the pinnes, well smoothed, the shank well shapen, the points well and round filed, canted and sharpened." At that time pins of good quality were made of brass; but a large proportion of those against which the legislative enactment was directed were made of iron wire blanched and passed as brass pins. To a large extent the supply of pins in England was received from France till about 1560, in which year the manufacture was introduced into Gloucestershire by John Tilsby. His business flourished so well that he soon gave employment to 1000 persons, and Stroud pins attained a high reputation. In 1636 the pinmakers of London formed a trade union, and the manufacture was subsequently established at Bristol and Birmingham, the latter town ultimately becoming the principal centre of the industry. So early as 1775 the attention of the enterprising colonists in Carolina was drawn to the manufacture by the offer of prizes for the first native-made pins and needles. At a later date several pin-making machines were invented in the United States. During the war of 1812, when the price of pins rose enormously, the manufacture was actually started, but the industry was not fairly successful till about the year 1836 when the Howe Manufacturing Company was formed at Birmingham, Connecticut. Previous to this an American, Lemuel W. Wright, had in 1824 secured in England a patent for a machine to make solid-headed pins, which established the industry on its present basis.

The old form of pin consisted of a shank with a separate head of fine wire twisted round and secured to it. Fine wire for heads was first wound on a lathe round a spilt the exact circumference of the pin shanks to be headed. In this way a long elastic spiral was produced which had next to be cut into heads, each consisting of two complete turns of the spiral. These heads were softened by heat, bent and forced into the head of the pin and a strong head was thus formed. The number of such heads as his die-block was fitted for. All the other operations of straightening the wire, cutting, pointing, &c., were separately performed, and these numerous details connected with the production of a common pin were seized on by Adam Smith as one of the most remarkable illustrations of the advantages of the division of labour.

The beautiful automatic machinery by which pins are now made of single pieces of wire is an invention of the 19th century. In 1817 a communication was made at the Patent Office by Seth Hunt, describing a machine for making pins with "head, shaft and point in one operation." The patent was then held to be a fraud, as Hunt was cut off and held in a die till a globular head was formed on one end by compression, and the other end was pointed by the revolution around it of a roughened steel wheel. This machine does not appear to have come into use; but in 1824 Wright patented the point of a pin separately and the head of the pin, similar to that of the machine now employed. A factory equipped with his machines was established in London, but the company which owned it was not successful. The plant passed into the hands of Daniel Foot-ner. In 1825 his metal-making machine, using a revolvingdraught of air, was patented for five years from 1836, and his firm was the first to carry on the production of machine-made solid-headed pins on a commercial basis. In a modern pin-making machine wire of suitable twist and temper is run into a heating furnace, and on passing through straightening pins or studs set in a table. When a pin length has entered it is caught by lateral jaws, beyond which end of the end projects to form a pin-head. Against this end a steel headstock in a revolving arrangement is pressed, the head of the machine made, and the head piece dropped into a slit sufficiently wide to pass the wire through but retain the head. The pins are consequently suspended by the head while their projecting extremities are held against a revolving cutter, by which they are marked. They are next cleaned by being boiled in weak beer, and then arranged in a copper pan in layers alternating with layers of grained tin. The contents of the pan are covered with water over which a quantity of charcoal is put to give off carbonic acid gas (bitartrate or eugenol) which is directed against the pins. After several hours the brass pins are coated with a thin deposit of tin, which gives them their silvery appearance. They are then washed in water, and dried and polished by being revolved in a barrel, mixed with dry bran or fine sawdust, from which they are washed, or finished pins. A large proportion of the pins sold are stuck into paper by an automatic machine not less ingenious than the pin-making machine itself. Mourning pins are made of iron wire, being immersed in a bath of molten lead, which gives them their "eruption" or growth. A considerable variety of pins, including the ingeniously coiled, bent and twisted nursery safety pin, ladies' hairpins, &c., are also made by automatic machinery. The sizes of ordinary pins range from 3-in. to 2½-in. in diameter, and the finest grades are made for dentists, gynaecologists, or for use in the manufacture of grained or finish gilt-pin used by entomologists. 4500 of which weigh about an ounce.

**PINA, RUY DE (1440–1521)**, Portuguese chronicler, was a native of Guarda. He acted as secretary of the embassy sent by King John II. to Castile in the spring of 1482, and in the following September returned there as sole envoy. He was present at the coronation of the duke of Braganza at Evora in 1493, and in 1494 went to Rome as secretary of an embassy to Pope Innocent VII. On his return, the king charged him to write a history of his reign and gave him a pension for his support. Following the arrival of Columbus from his first voyage in 1493, Pina was one of the commissaries despatched to Barcelona by John II. to negotiate with the Catholic sovereigns respecting the limits of their respective jurisdictions. In September 1495 he attested the will of John II. in his capacity as a notary public, and on the 27th of October of the same year he was present at his master's death and read his testament. King Manoel confirmed his pension and appointed him in 1497 chronicler of the kingdom, keeper of the archives and royal librarian, with a suitable salary. By 1504 Pina had completed his chronicles of Alphonso V. and John II. King John III. charged him with a history of his father, Manoel, and at his death Pina had carried it down to the capture of Azamor, as we know from Damiao de Goes, who used it in preparing his own chronicle of that monarch.

It is probable that the chronicles of the early kings of Portugal from Sancho I. to Alphonso IV. which were published under Pina's name in the 18th century were written by Fernao Lopes and edited by Pina, while that of King Duarte seems to have been the joint production of Lopes and Azurara, with Pina again as the editor only. Pina was a favourite of fortune during his life, for, apart from royal benefactions, he received presents from public men who wished to figure well in his books, and after his death he obtained the credit for work that was not his. His authority as an historian is considerable, and his frankness is said to have provoked remark from contemporaries.

Pina's chronicles of King Alphonso V. were first published in Lisbon in 1853; those of King Duarte and King Alphonso V. in vol. i. of the *Coleccio de libros ineditos da historia portuguesa*. 
PINACOTHECA—PINCKNEY, C. C.

(1757–1824), American statesman, was born on the 26th of October 1757 at Charleston, South Carolina; he was the son of Charles Pinckney (1731–1784), first president of the first South Carolina Provincial Congress (Jan. to June 1773), and a cousin of Charles Cotesworth Pinckney and Thomas Pinckney. He was studying law at the outbreak of the War of Independence, served in the early campaigns in the South, and in 1779 was elected to the South Carolina House of Representatives. He was captured by the British at the fall of Charleston (1780), and remained a prisoner until the close of hostilities. He was elected a delegate to the Congress of the Confederation in 1783, 1785 and 1786, and in 1786 he moved the appointment of a committee “to take into consideration the affairs of the nation,” advocating in this connection an enlargement of the powers of Congress. The committee having been appointed, Pinckney made chairman of a sub-committee which prepared a plan for amending the articles of confederation. In 1787; he was a delegate to the Federal constitutional convention, and on the same day (May 29) on which Edmund Randolph (q.v.) presented what is known as the Virginia plan, Pinckney presented a draft of a constitution which is known as the Pinckney plan. Although the Randolph resolutions were made the basis on which the new constitution was framed, Pinckney’s plan seems to have been much drawn upon. Furthermore, Pinckney appears to have made valuable suggestions concerning the phrasing and matters of detail. On the 18th of August he introduced a series of resolutions, and to him should probably be accredited the authorship of the substance of some thirty-one or thirty-two provisions of the constitution.1

1 The “Pinckney Plan” has been the subject of considerable discussion. When, in 1818, John Quincy Adams was preparing the journal of the convention for publication and discovered that the Pinckney plan was missing, he wrote to Pinckney for a copy, and to this letter the Court reporter replied that he had no original draft or a copy of a draft which differed from the original in no essentials. But as this was found to bear a close resemblance to the draft reported by the committee of detail, Madison and others, who had been members of the convention, as well as historians, treated it as spurious, and for years Pinckney received little credit for his work in the convention. Later historians, however, notably J. Franklin Jameson and Andrew C. McLaughlin, have attributed to him the suggestion of a number of provisions of the constitution and the plan chiefly from his speeches, or alleged speeches, and from certain papers of James Wilson, a member of the committee of detail, one of which papers is believed to be an outline of the Pinckney plan. See “Outline of Pinckney’s Plan,” in The American Historical Review, 1907, vol. ii.; A. C. McLaughlin, “Outline of Pinckney’s Plan for a Constitution,” in The American Historical Review, 1907, vol. ii.; C. C. Nott, The Mystery of the Pinckney Draught (New York, 1908), an attempt by a former chief-justice of the U.S. Court of Claims to prove that Pinckney was president of the State Convention of 1790 that framed a new constitution for South Carolina, was governor of the Province before 1770, a member of the South Carolina House of Representatives in 1792–1796, and again governor from 1796 to 1798. From 1790 to 1801 he was a member of the United States Senate. He entered public life as a Federalist, but later became the leader in organizing the Democratic-Republican party in his state, and contributed largely to the success of Thomas Jefferson in the presidential election of 1800. By Jefferson’s appointment he was American minister to Spain from 1801 to 1805. In general his mission was a distinct failure, his arrogance and indiscretions finally causing the Spanish government to request his recall. He was elected to the state House of Representatives in 1805; was again governor of South Carolina from 1806 to 1808, in 1810–1814 was once more a member of the state House of Representatives, in which he opposed President Madison’s war policy, and from 1819 to 1821 was a member of the National House of Representatives, in which he opposed the Missouri Compromise in a brilliant speech. He died at Charleston, South Carolina, on the 29th of October, 1824.

HENRY L. ELLIOTT (1758–1824) was a member of the state House of Representatives in 1816–1832, and of the National House of Representatives in 1832–1837.

PINCKNEY, CHARLES COTESWORTH (1740–1825), American statesman, was born in Charleston, South Carolina, on the 25th of February 1746, the son of Charles Pinckney (d. 1758),2 by his second wife, the celebrated girl planter, Eliza Lucas. When a child he was sent to England, like his brother Thomas after him, to be educated. Both of them were at Westminster and Oxford and were called to the bar, and for a time they studied in France at the Royal Military College at Caen. Returning to America in 1769, C. C. Pinckney began the practice of law at Charleston, and soon became deputy attorney-general of the province. He was a member of the first South Carolina provincial congress in 1775, served as colonel in the South Carolina militia in 1776 and 1777, was chosen president of the South Carolina Senate in 1778, took part in the Georgia expedition and the attack on Savannah in the same year, was captured at the fall of Charleston in 1780 and was kept in close confinement until 1782, when he was exchanged. In 1783 he was commissioned a brevet brigadier-general in the continental army. He was an influential member of the constitutional convention of 1787, advocating the counting of all slaves as a basis of representation and opposing the abolition of the slave-trade. He opposed as “impracticable” the election of representatives by popular vote, and also opposed the payment of senators, who, he thought, should be men of wealth. Subsequently Pinckney bore a prominent part in securing the ratification of the Federal constitution in the South Carolina convention called for that purpose in 1788 and in framing the South Carolina State Constitution in the convention of 1790. After the organization of the Federal government, President Washington offered him at different times appointments as associate justice of the Supreme Court (1789), secretary of war (1790) and secretary and the document sent by Pinckney to Adams in 1818 is a genuine copy of his original plan.

2 Charles Pinckney, the father, was long prominent in colonial affairs; he was attorney-general of the province in 1735, speaker of the assembly in 1738 and in 1740, chief justice of the province in 1752–1753, and agent for South Carolina in England in 1753–1758. He was the uncle of Charles Pinckney (1731–1784), and the great-uncle of Charles Pinckney (1757–1824). Eliza Lucas Pinckney (1728–1793), the wife of Dr. John Lucas of the British army, who about 1738 removed from Antigua to South Carolina, where he acquired several plantations. He was almost immediately recalled to Antigua, and his daughter under-
of state (1795), each of whom he declined; but in 1796 he succeeded James Monroe as minister to France. The Directors refused to receive him, and he retired to Holland, but in the next year, Elbridge Gerry and John Marshall having been appointed to act with him, he again repaired to Paris, where he is said to have made the famous appeal to a velled demand for a "loan" (in reality for a gift), "Millions for defence, but not one cent for tribute," —another version is, "No, not a sixpence." The mission accomplished nothing, and Pinckney and Marshall left France in disgust, Gerry (q.v.) remaining. When the correspondence of the commissioners was sent to the United States Congress the letters "X," "Y" and "Z," were inserted in place of the names of the French agents with whom the commission treated—hence the "XYZ Correspondence," famous in American history. In 1800 he was the Federalist candidate for vice-president, and in 1804 and again in 1808 for president, receiving 14 electoral votes in the former and 47 in the latter year.

From 1805 until his death, on the 16th of August 1825, he was president-general of the Society of the Cincinnati.

PINCKNEY, THOMAS (1750–1825), American statesman and diplomat, was born in Charleston, South Carolina, on the 23rd of October 1750, a younger brother of Charles Cotesworth Pinckney (q.v.). Educated in England, he returned to Charleston in 1773, and was in the latter part of 1774. During the War of Independence his early training at the French military college at Caen enabled him to render effective service to General Benjamin Lincoln in 1778–1779, to Count d'E斯塔ing (1779), to General Lincoln in the defence of Charleston and afterwards to General Horatio Gates. In the battle of Camden he was badly wounded and captured, remaining a prisoner for more than a year. Subsequently he was governor of South Carolina in 1787–1789; presided over the state convention which ratified the Federal constitution in 1788; was a member of the state legislature in 1791; and was United States minister to Great Britain in 1792–1796. During part of this time (1794–1795) he was also envoy extraordinary to Spain, and in this capacity negotiated (1795) the important Treaty of San Lorenzo el Real; by that treaty the boundary between the United States and East and West Florida and between the United States and "Louisiana" was settled (Spain relinquishing all claims east of the Mississippi above 31° N. lat.), and the United States secured the freedom of navigation of the Mississippi to its mouth with the right of deposit at New Orleans for three years, after which the United States was to have the same right either to deposit or to stop a vessel of some other place on the Mississippi to be designated by Spain. In 1796 Pinckney was the Federalist candidate for vice-president, and in 1797–1801 he was a Federalist representative in Congress. During the War of 1812 he was a major-general. In 1825 he succeeded his brother as president-general of the Society of the Cincinnati. He died in Charleston on the 2nd of November 1828. Pinckney, like many other South Carolina revolutionary leaders, was of aristocratic birth and politics, closely connected with England by ties of blood, education and business relations. This renders the more remarkable their attitude in the War of Independence, for which they made great sacrifices. Men of Pinckney's type were not in sympathy with the progressive democratic spirit of America, and they began to withdraw from politics after about 1800.

See C. C. Pinckney, Life of General Thomas Pinckney (Boston, 1895).

PINDAR (Gr. Πινδάρος, s. 522–443 B.C.), the great lyric poet of ancient Greece, was born at Cynoscephalae, in Boeotia, at the time of the Pythian games (fr. 175, Bergk1, 193), which is taken by Böckh to be 522 B.C. He would thus be some twenty years younger than Sappho of Mytilene. He was the son of Diaphantes and Cleodice (or Cleidice). The traditions of his family have left their impress on his poetry, and are not without importance for a correct estimate of his relation to his contemporaries. The clan of the Aegidae—tracing their line from the hero Aegaeus—belonged to the "Cadmean" element 1

1 The references are to the edition of Pindar by C. A. M. Fennell (1893–1899), and the fourth edition of Bergk's Poetae lyrici Graeci.
victory of the Athenian Megacles, he begins thus: "Fairest of
prudes is the renown of Athens for the mightiest race of
the Alcaeimaeidae. What homeric character, how? Would
Diomed call me by a name that should sound more glorious for
Hellas to hear?" Referring to the fact that an Aeginetan victor
in the games had been trained by an Athenian, he says (Nem.
V. 49) "meet it is that a shaper of athletes should come from
Athens"—and recalling how often Pindar compares the poet's
efforts to the athlete's, we may well believe that he was think-
ing of his own early training at Athens.

Pindar's versatility as a lyric poet is one of the characteristics
remarked by Horace (Odes, iv. 2), and is proved by the frag-
ments, though the poems which have come down entire
represent only one class of compositions—the
Epinicia, or odes of victory, commemorating successes in
the great games. The lyric types to which the fragments belong,
though it cannot be assumed that the list is complete, are
at least numerous and varied.

(1) "Τάυρον, Hymns to deities—as to Zeus Ammon. to Persephone,
to the Lykeia, to the Thesmophoria. The fragmentary Τάυρον
texts entitled Ποίεσες seems to have celebrated the dedica-
factions, expressing prayer or prayer for the help of a
proteciting god, especially Apollo, Artemis or Zeus.

(2) "Διήροιται, Dithyrambs, odes of a lofty and impassioned strait.

(3) "Παράτεινη, Dithyrambs, odes of a lofty and impassioned strain,
aptly used as a swan song. 'ox-driving,' perhaps meaning
"my heart is full, I have an ox to drive with the corning,
choral chants for worshippers approaching a shrine. One
was written by Pindar for the Delians, another for the
Aeginetans.

(5) Πανάθηναι, Choral Songs for Maidens. The reference in Pyth.
Ili. 136, 137—for the poet's house is illustrated by the fact
that one of these Παναθηναι invok-
"Pan, lord of Arcadia, attendant of the Great Mother, watch
her awful shrine" (fr. 72, Bergk 4, 95). (6) "Προφητιστικα, Choral
Diaspores, odes for the delivery of a choral lyre, which was
used from an early date in the cult of Apollo, and afterwards in
the Greek colonies, especially Dionysus. To this class belongs
one of the finest fragments (84, Bergk 4, 107), written for the
Thebans in connexion with propitiatory rites after an eclipse of
the sun, probably that of the 3oth of April 463 B.C.

(7) "Επιμικρυ, Songs of Praise (for men, while hymn were for gods),
to be sung by a κώμος or festal company.

In strictness Επιμικρυ was the genus of which Επιμικρυ was a
species; but the latter is more conveniently treated as a distinct
kind.

Pindar wrote the Ακαηαι and for Alexander I. (son of Amynatas), king of Macedon.

(8) Σύλλυ, and Συλλυ. The usual sense of Σύλυ is a drinking-song, taken
up one guest after another at a banquet. But Pindar's σύλυ
were specific and antistrophic. Ovid was to be seen as a
chorus of the Ιπποθησικ, attached to the temple of Aphrodite
Ourania, when a certain Xenophon offered sacrifice before going
to be crowned at Olympia. Another brilliant fragment, for Theocles
of Tegea, has an erotic character (fr. 16, Bergk 4, 137),
with choral dance and the music of the flute, either at the
burial of the dead or in commemorative rituals. Some of the
most beautiful fragments belong to this class (166, Bergk 4, 137).

The Epinicia.—The Επιμικρυ (sc. μηδεις), or Επιμικρυ (sc.
Ουμοι), or "Odes of Victory," form a collection of forty-four odes, traditionally divided into four books, answering to
the four great festivals: (1) "Ολυμπιονικα, (sc. ουμοι): fourteen odes
for winners of the wild olive-wreath in the Olympic games, held
at Olympia in honour of Zeus once in four years; (2) Πυθιονικα:
twelve odes for winners of the laurel-wreath in the Pythian
games held at Delphi in honour of Apollo, once in four years,
the third of each Olympiad; (3) Νεμειονικα: eleven odes for
winners of the pine-wreath in the Nemean games, held at Nemea,
in honour of Zeus, once in two years, the second and fourth of
each Olympiad; and (4) Ιστιονικα: seven odes for winners of
the parsley wreath in the Isthmian games, held at the Isthmus

(1) A. Schäfer, Demosthenes and his Zeit, iii. 119.

1 It will be remarked that history requires us to modify the state-
ment in Milton's famous lines:—

The great Ethimian conqueror had no sense
The house of Pindar, when temple and tower
Went to the ground."

Indeed, the point of the incident depends much on the fact that
the temples and Pindar's house were classed together for exemption.

Compare Jebb, Attic Orators, i. 143.

of Corinth, in honour of Poseidon, once in two years, the first and third of each Olympic. The Greek way of citing an ode is by the nomin. παρά, followed by the numeral, e.g. "the ninth Olympian," is "Ολυμπιανός θ". The chronological range of the collection (so far as ascertainable) is from 502 B.C. (Pyth. i.) to 452 B.C. (Ol. v.). With respect to the native places of the victors, the geographical distribution is as follows: for the mainland of Greece proper, 13 odes; for Aegina, 11, for Sicily, 15; for the Epizephyrian Locrians (southern Italy), 2; for Cyrene (Africa), 3.

The general characteristics of the odes may be briefly considered under the following heads: (1) language; (2) treatment of theme; (3) sentiment—religious, moral, and political; (4) relation to contemporary art.

1. The diction of Pindar is distinct in character from that of every other Greek poet. The Greek way of citing an ode is by the nomin. παρά, followed by the numeral, e.g. "the ninth Olympian" is "Ολυμπιανός θ". The chronological range of the collection (so far as ascertainable) is from 502 B.C. (Pyth. i.) to 452 B.C. (Ol. v.). With respect to the native places of the victors, the geographical distribution is as follows: for the mainland of Greece proper, 13 odes; for Aegina, 11, for Sicily, 15; for the Epizephyrian Locrians (southern Italy), 2; for Cyrene (Africa), 3.

2. The diction of Pindar is distinct in character from that of every other Greek poet. The Greek way of citing an ode is by the nomin. παρά, followed by the numeral, e.g. "the ninth Olympian," is "Ολυμπιανός θ". The chronological range of the collection (so far as ascertainable) is from 502 B.C. (Pyth. i.) to 452 B.C. (Ol. v.). With respect to the native places of the victors, the geographical distribution is as follows: for the mainland of Greece proper, 13 odes; for Aegina, 11, for Sicily, 15; for the Epizephyrian Locrians (southern Italy), 2; for Cyrene (Africa), 3.

3. The religious feeling of Pindar is strongly marked in the odes. "From the gods are all means of human excellence."

He will not believe that the gods, when they dined with Tantalus, ate his son Peleus; rather Poseidon carried off the youth to Olympus. That is, his reason for rejecting a scandalous story about the gods is purely religious, as distinct from moral; it shocks his conception of the divine dignity. With regard to oracles, he inculcates precisely such a view as would have been most acceptable to the Delphic priesthood, viz. that the gods do illumine their prophets, but that human wit can foresee nothing which the gods do not choose to reveal. A mystical doctrine of the soul's destiny after death appears in some passages (as Ol. ii. 66 sq.). Pindar was familiar with the idea of metempsychosis (cf. ibid. 68), but the attempt to trace Pythagoreanism in some phrases (Pyth. ii. 34, iii. 74) appears unsafe.

The belief in a fully conscious existence for the soul in a future state, determined by the character of the earthly life, entered into the teaching of the Eleusinian and other mysteries. Comparing the fragment of the Ἑρεφος (114, Bergk, 137), we may probably regard the mystic or esoteric element in Pindar's theology as due to such a source.

b. The moral sentiment pervading Pindar's odes rests on a constant recognition of the limits imposed by the divine will on human effort, combined with strenuous exhortation that each man should strive to reach the limit allowed in his own case. Native temperament (φύς) is the grand source of all human excellence (ἀρετή), while such excellences as can be acquired by study (δοκατά ἀρεταί, Ol. ix. 100) are of relatively small scope—the sentiment, we may remark, of one whose thoughts were habitually conversant with the native qualities of a poet on the one hand and of an athlete on the other. The elements of ὡγες δῆβοι—"sane happiness," such as have least reason to dread the jealousy of the gods—are substance sufficient for daily wants and good repute (ἐθάντως). He who has such should not "seek to be a god," "Wealth set with virtues" (πλοῦτος ἀρεταὶ διδυμενής), as gold with precious gems, is the most fortunate lot, because it affords the smallest opportunities for honourable activity. Pindar does not rise above the ethical standard of an age which said, "love thy friend and hate that foe" (cf. Pyth. ii. 83; Isthm. iii. 65). But in one sense he has a moral elevation which is distinctively his own; he is the glowing prophet of genuine emulation and of reverent self-control.

c. The political sentiments of the Theban poet are suggested by Pyth. xi. 52: "In politics I find the middle state crowned with more enduring good; therefore praise I not the despot's portion; those virtues move my zeal which serve the folk." If in Pyth. ii. 87, a democracy is described as ὁ λαβὼν στράτου, "the raging crowd," it is to be noted that the ode is of Hiero of Syracuse, and that the phrase clearly refers to the violence of those democratic revolutions which, in the early part of the 5th century B.C., more than once convulsed Sicilian cities. At Thebes, after the Persian wars, a "constitutional oligarchy" (ἅγγαρα ἱδρυμος, Thuc. iii. 62) had replaced the narrower and less temperate oligarchy of former days (δυναστεία οι μετὰ βίγματος); and in this we may probably recognize the phase of Greek political life most congenial to Pindar. He speaks of a king's lot as unique in its opportunities (Ol. i. 113); he sketches the character of an ideal king (Pyth. iii. 71); but nothing in his poetry implies liking for the τιτανικός as a form of government. Towards the Greek princes of Sicily and Cyrene his tone is ever one of manly independence; he speaks as a Greek citizen whose lineage places him on a level with the proudest of the Dorian race, and whose office invests him with an almost sacred dignity. In regard to the politics of Hellas at large, Pindar makes us feel the new sense of leisure for quiet pursuits and civilizing arts which came after the Persian wars. He honours " Tranquillity, the friend of citizens" (Ἀγαθία φίλος, Ol. iv. 16). The epic poet sang of wars; Pindar celebrates the "rivalries of peace."

4. Pindar's genius was boldly original; at the same time he was an exquisite artist. "Mine be it to invent new strains, mine the skill to hold my course in the chariot of the Muses; and may courage go with me, and power of ample grasp" (Ol.
Here we see the exulting sense of inborn strength; in many other places we perceive the feeling of conscious art—as in the phrase δακδάλλης, so apt for his method of inflecting an ode with mythical subjects, or apt for the method of inflating a song to the front of a stately building (Ol. vi. 3). Pindar’s sympathy with external nature was deeper and keener than is often discernible in the poetry of his age. It appears, for example, in his welcome of the season when “the chamber of the hours is opened, and delicate plants perceive the fragrant spring” (fr. 53, Bergk 4; 75); in the passage where Jason invokes “the rushing strength of waves and winds, and the nights, and the paths of the sun” (Pyth. iv. 193); in the lines on the eclipse of the sun (fr. 84, Bergk 107); and in the picture of the eruption, when Etina, “pillar of the sky, nurse of keen snow all the year,” sends forth “purer puffs” of fire unapproachable” (Pyth. ii. 5). The poet’s feeling for colour is often noticeable—as in the beautiful story of the birth of Lamus—when Evadne lays aside her silver pitcher and her girdle of scarlet web; the babe is found, “its delicate body steeped in the golden and deep purple rays of pansies” (Ol. vi. 55).

The spirit of art, in every form, is represented by Pindar by χάρατος “the source of all delights to mortals” (Ol. i. 30)—or by the personified Charites (Graces). The Charites were often represented as young maidens,. The Greek conception from which the worship of the Charites sprang, the instinct of beautiful art was inseparable from the sense of natural beauty. The period from 560 to 510 B.C., is most of Pindar’s extant odes belong, marked a stage in the development of Greek sculpture. The schools of Argos, Sicyon and Aegina were effecting a transition from archaic types to the art which was afterwards matured in the age of Phidias. Olympia forms the central link between Pindar’s poetry and Greek sculpture. From about 500 B.C. onwards sculpture had been applied to the commemoration of athletes, chiefly at Olympia. In a striking passage (Nem. v. ad. init.) Pindar recognizes sculpture and poetry as sister arts employed in the commemoration of the athlete, and contrasts the merely local effect of the statue with the wide diffusion of the poem. ‘No sculptor I, to fashion images that shall stand idly on one pedestal for aye; no, go thou forth from Aegina, sweet song of mine, on every freighted ship. When each knight of Marathon and Atticus will come to Pindar and contemplate his work. Thus (1) the sculptures on the east pediment of the temple at Aegina represented Heracles coming to seek the aid of Telemon against Troy—a theme brilliantly treated by Pindar in the fifth Isthmian; (2) Hiero’s victory in the chariot-race was commemorated at Olympia by the joint work of the sculptors Onatas and Calamis; (3) the Gigantomachia, (4) the wedding of Heracles and Hebe, (5) the war of the Centaurs with the Lapithae, and (6) a contest between Heracles and Apollo, are instances of mythical material treated alike by the poet and by sculptors of his day. The contemporary improvements in town architecture, introducing spacious and well-planned streets, as the στεπροτήσσαρα at Cyrene (Pyth. v. 87), suggests his frequent comparison with the “marble buildings of the inhabited world” (πλαταιών προοδών—κοινωνίας κλειδων, Nem. vi. 47; Isthm. vi. 22). A song is likened to cunning work which blends gold, ivory and coral (Nem. vii. 78). Pindar’s feeling that poetry, though essentially a divine gift, has a technical side (σοφία), and that on this side it has an historical development like that of other arts, is forcibly illustrated by his reference to the inventions (σοφίσματα) for which Corinth had early been famous. He instances (1) the development of the dithyramb, (2) certain improvements in the harnessing and driving of horses, and (3) the addition of the pediment to temples (Ol. xii. 21).

In the development of Greek lyric poetry two periods are broadly distinguished. During the first, from about 600 to 500 B.C., lyric poetry is local or tribal—as Alcaeus and Sappho write for Lesbians, Alcman and Stesichorus for Dorian.

The second period, which takes its rise in the sense of Hellenic unity created by the Persian wars, the lyric poet addresses all Greece. Pindar and Simonides are the great representatives of this second period, to which Bacchylides, the nephew of Simonides, also belongs. These, with a few minor poets, are classed by German writers as die uniervellen Meliker. The Greeks usually spoke, not of "lyric," but of "melic" poetry (i.e. meant to be sung, and not, like the epic, recited); and "universal melic" is lyric poetry addressed to all Greece. But Pindar is more than the chief extant lyrist. Epic, lyric and dramatic poetry succeeded each other in Greek literature by a natural development. Each of them was the spontaneous utterance of the age which brought it forth. In Pindar we can see that phase of the Greek mind which produced Homeric poetry, passed over into the phase which produced Athenian drama. His spirit is often thoroughly dramatic—witness such scenes as the interview between Jason and Pelias (Pyth. iv.), the meeting of Apollo and Chiron (Pyth. ix.), the episode of Castor and Polydeuces (Nem. x.), the entertainment of Heracles by Telamon (Isthm. v.). Epic narrative alone was no longer enough for the men who had known that great trilogy of national life, the Persian invasions; they longed to see the heroes moving and to hear them speaking. The poet of Olympia, accustomed to see beautiful forms in vivid action or vivid art, was well fitted to be the lyric interpreter of the new dramatic impulse. Pindar has more of the Homeric spirit than any Greek lyric poet known to us. On the other side, he has a genuine, if less evident, kinship with Aeschylus and Sophocles. Pindar’s work, like Olympia itself, illustrates the spiritual unity of Greek art.

The fact that certain glories and lacunae are common to all our MSS. of Pindar make it probable that these MSS. are derived from a common archetype. The MSS. of the age of Phidias, sometimes presuppose a purer text than MSS. of the age of the comm. of the instances (A.D. 160). The archetype of our MSS., then, have not been older than the end of the 2nd century. Our MSS. fall into two general classes: (1) the older, representing a text which, though corrupt, is more nearly the original of Pindar than the later, which exhibits the traces of a Byzantine recension, in others words, of lawless conjecture, down to the 14th or 15th century.

To the first class belong Parisinus 7, breaking off in Pyth. v.; Ambrosianus 1, which has only Ol. i. xii.; Medicus 2; and Vaticanus 2—the two last-named being of the highest value. The editto princeps is the Aldine (Venice, 1513). A modern study of Pindar may be almost said to have begun with C. G. Heyne’s edition of 1792. The MSS. are again analyzed by H. Gomperz (1881) and L. J. Alfoldi (1882). But August Böckh (1811-1821), who was assisted in his commentary by L. Dissen, is justly regarded as the founder of a scientific treatment of the poet. The edition of Theodor Bergk (Poetica lyricorum Graecorum, 1851) is by far the best, but it still contains the boldness of conjecture, as that of Tycho Mommsen (1864) by a sometimes excessive adherence to MSS. A recession by W. Christ has been published in Teubner’s series (2nd ed., 1890), also with Prolegomena and commentary (1896); and by O. Schrader (1894). The complete edition of J. W. Donaldson (1841) has many merits, but that of C. A. M. Fennell (1879-1883; new ed., 1890-1893) is better adapted to the needs of English students. The Olympia verses have been edited by E. L. Gildersleeve (1885), the Nemesis and Isthmia by J. B. Burck (1899, 1892); the Scholia by E. Abel (1860, unfinished) and A. B. Brachmann (1893). There is a Special edition by J. Rumpel (1885). The translation into English verse by E. Weinmann (1888) is the best, but the translation by J. C. Barr (1875), and of the Olympic Odes by Cyril Mayne (1906). Pindar’s metres have been analysed by H. H. Schmidt. Geschichte der griechischen Poesie (Leipzig, 1868-1872). On Pindar generally, see monographs on the earlier literature will be found in Engelmann, Scriptores graeci (1881); see also L. Bornemann, in Bursan’s Jahresbericht, (1904), with special reference to chronological questions and Pyth. ii. iii. Some considerable fragments of the poems were discovered in 1906 by B. P. Grenfell and A. S. Hunt. (see Oxyrhynchus papyri, pt. vi, pp. 24-81); some critical notes will be found in Classical Review, Feb. 1908 (E. A. Houseman).

PINDARICS, the name by which was known a class of loose and irregular odes mostly in fashion in England and close
of the 17th and the beginning of the 18th century. The invention is due to Abraham Cowley, who, probably in Paris—"a place where he had no other books to direct him"—and perhaps in 1650, found a text of Pindar and determined to imitate the Greek poetry in English, without having comprehended the system upon which Pindar's prosody was built up. Cowley published, however, in 1656, fifteen Pindarique Odes, which became the model on which countless imitators founded their pindarics. The erroneous form of these poems, which were absolutely without discipline of structure, was first exposed by Congreve, exactly half a century later, he very justly describing them as "bundles of rambling incoherent thoughts, expressed in a like parcel of irregular stanzas, which also consist of such another complication of disproportioned, uncertain and perplexed verses and rhymes." This is harsh, but it describes a pindaric with absolute justice. Cowley had not been aware that "there is nothing more regular than the Odes of Pindar," and that his poems were constructed in harmony with rigid prosodical laws in strophe, antistrophe and epode; "the liberty which Pindar took in his numbers, which has been so much misunderstood and misapplied by his pretended imitators, to only show his genius in different odes; but in each particular ode they are ever correspondent one to another in their turns, and according to the order of the ode." These excellent critical remarks were made by Congreve in his Discourse on the Pindarique Ode of 1706, and from that date forward the use of pindarics ceased to be so lax and frantic as it had been during the previous fifty years. The time had now passed in which such a critic as Sprat could praise "this loose and unconfined measure" as having "all the grace and harmony of the most confined." It began to be felt that the English pindaric was a blunder founded upon a misconception. If we examine Cowley's "Resurrection," which was considered in the 17th century to be a model of the style, and "truly pindarical," we find it to be a shapeless poem of 64 lines, arbitrarily divided, not into strophes, but into four stanzas of unequal volume and structure; the lines which form these stanzas are of lengths varying from three feet to seven feet, with rhymes repeated in wilful disorder, the whole forming a mere vague caricature of Pindar's brilliant odes. The very laxity of these pindarics attracted the poets of the unlyrical close of the 17th century, and they served the purpose not only of Dryden and Pope, but of a score of lesser poets, among whom Oldham, Mrs Behn, Otway, Sprat, Flatman and many others were prominent. The pindaric became the almost necessary form in which to indite a poem of compliment on a birth, a wedding or a funeral. Although the vogue of these forms hardly survived the age of Anne, something of the vicious tradition of them still remained, and even in the odes of Wordsworth, Shelley and Coleridge the broken versification of Cowley's pindarics occasionally survives. Tenneyson's Ode on the Death of the Duke of Wellington (1852) is the latest important specimen of a pindaric in English literature. (E. G.)

**PINDARIS,** a word of uncertain origin, applied to the irregular horsemen who accompanied the Mahratta armies in India during the 18th century when the Mughal Empire was breaking up; loosely organized under self-chosen leaders, each band was usually attached to some or other of the great Mahratta chieftains. Their special characteristic was that they received no pay, but rather purchased the privilege of plundering on their own account. The majority of them seem to have been Mahomedans: when the regular forces of the Mahrattas had been broken up in the campaigns conducted by Sir Arthur Wellesley and Lord Lake in 1820-0, the Pindaris made their headquarters in Malwa, under the tacit protection of Sindiah and Holkar. They were accustomed to assemble every year at the beginning of November, and sally forth by British territory in search of plunder. In one such raid upon the Masulipatam coast they plundered 330 villages, killing or wounding 682 persons, torturing 3600 and carrying off property worth a quarter of a million. In 1808-09 they plundered Gujara and in 1812 Mirzapur. In 1814 the permission to 25,000 to 30,000 horsemen, half of them well armed. At last the evil became intolerable, and in 1817 the marquess of Hastings obtained the consent of the East India Company to the organized campaign, known as the Pindari War. The Pindaris were surrounded on all sides by a great army, consisting of 120,000 men and 500 guns, which converged upon them from Bengal, the Deccan and Gujarat under the supreme command of Lord Hastings in person. Sindiah was overawed and forced to sign the treaty of Gwalior, consenting to aid in the extirpation of the Pindaris, whom he had hitherto protected. The Peshwa at Poona, the Bhonsla raja at Nagpur and the army of the infant Holkar each took up arms, but were separately defeated. The Pindaris themselves offered little opposition. Amir Khan, by far their most powerful leader, accepted the conditions offered to him; and his descendant is now Nawab of the state of Tonk in Rajasthan. The rest surrendered or were hunted down, the fate of Chitul, one of the most notorious, being to perish in a tiger's den. These military operations were followed by the pacification of Central India under the administration of Sir John Malcolm.

See J. Grant Duff, History of the Mahrattas (1892); and Major H. Bladensburg, Marquess of Hastings (Rulers of India Series) (1893).

**PINDADAN KHAM**, a town of British India, in the Jhelum district of the Punjab, situated near the right bank of the river Jhelum, on the Sind-Sagar branch of the North-Western railway. Pop. (1901), 13,770. It is an important centre of trade, and its manufactures include boats, brass-ware, pottery, embroidered scarves and riding-whips.

**PINDUS**, the ancient name of the rugged group of mountains which separates Theissaly from Epirus, and branches south in various directions. The geographical name is sometimes extended over all these branches, and so reaches from Aetolia to the Gulf of Lamia. The northern part of the ridge was known as Lacmon. There is no modern name covering the whole range, but its different parts have separate names. Several of them attain a height of 7000 ft. or more.

**PINE** (Lat. Pinus, Gr. πῖνον), a name given by the ancients to some of the resinous cone-bearing trees to which it is now applied, and, as limited by modern botanists, the designation of a large genus of true conifers, differing from the firs in their hard woody cone-scales being thickened at the apex, and in their slender needle-shaped leaves growing from a membraneous sheath, either in pairs or from three to five together—each tuft representing an abortive branch, springing from the axil of a partially deciduous scale-leaf, the base of which remains closely adherent to the stem. The numerous male catkins are generally arranged in dense whorls around the bases of the young shoots; the anther-scales, surmounted by a crest-like appendage, shed their abundant pollen by longitudinal slits; the two ovules at the base of the inner side of each fertile cone-scale develop into a pair of winged seeds, which drop from the opening scales when mature—as in the allied genera.

The pines are widely distributed over the north temperate zone, in the southern portions chiefly confined to the mountains, along which, in Central America, a few are found within the tropic; in more northern regions they frequently form extensive forests, sometimes hardly mingled with other trees. Their soft, straight-grained, resinous and often durable wood gives many finds a high economic value, and some are among the most esteemed of timber trees.

Of the two-leaved species, *P. sylvestris*, the pine of northern Europe, may be taken as a type. When growing in perfection it is one of the finest of the group, and perhaps the most picturesque of forest trees; attaining a height of from 70 to 120 ft., it is of conical growth when young, but in maturity acquires a spreading cedar or mushroom-like top, with a straight trunk of from 2 to 4 ft. in diameter at the base, and glossy twisted boughs, densely clothed at the extremities with glaucous green foliage, which contrasts strongly with the fiery red-brown bark. The leaves are rather short, curved, and often twisted; the male catkins, in dense cylindrical whorls, fill the air of the forest with their sulphur-like pollen in May or June, and fecundate the purple female flowers, which, at first sessile and erect, then
become recurved on a lengthening stalk; the ovate cones, about the length of the leaves, do not reach maturity until the autumn of the following year, and the seeds are seldom scattered until the third spring; the cone-scales terminate in a pyramidal

of the northern counties of England attest its abundance there in prehistoric times; and in the remoter post-Glacial epoch its range was probably vastly more extended. The tree is not at present indigenous in southern Britain, but when planted in suitable ground multiplies rapidly by the wind-sown seeds; on many of the sandy moors and commons natural pine woods of large extent have been thus formed during the last fifty years. The Scotch fir is a very variable tree, and certain varieties have acquired a higher reputation for the qualities of their timber than others; among those most prized by foresters is the one called the Braemar pine, the remaining fragments of the great wood in the Braemar district being chiefly composed of this kind; it is mainly distinguished by its shorter and more glaucous leaves and ovoid cones with blunt recurved spines, and especially by the early horizontal growth of its ultimately drooping boughs; of all varieties this is the most picturesque. On the European continent the Hagenau pine of Westphalia is esteemed for the straightness and good quality of its timber. The heart-wood of the finer kinds of Scotch fir is of a deep brownish-red colour, abounding in the resin to which its durability is probably due. For all indoor and most outdoor purposes it is as lasting as oak, and for ship planking is perhaps little inferior; from its lightness and elasticity it is well adapted for the construction of yachts and other small fast-sailing craft, and is said to be the best of all wood for masts and large spars; its weight varies from 30 to 40 lb the cubic foot. The sap-wood is more perishable, but it is useful for fences, casks and a variety of other purposes; soaking in lime-water renders it more lasting; great numbers of young pines are annually cut for railway sleepers, mining timber and numerous agricultural applications; large quantities are consumed for wood-pavement. The quality of the timber

recurred point, well marked in the green state and in some varieties in the mature cone, but in others scarcely projecting. *P. sylvestris* is found, in greater or less abundance, from the hills of Finmark and the plains of Bothnia to the mountains of Spain and even the higher forest-slopes of Etna, while in longitude its range extends from the shores of the North Sea to Kamchatka. Nowhere more abundant than in the Scandinavian peninsula, this tree is the true fir (*fur, furu*) of the old Norsemen, and still retains the name among their descendants in Britain, though botanically now classed as a pine. It grows vigorously in Lapland on the lower ground, and is found even at an elevation of 700 ft., while in south Norway it occurs up to 3000 ft., though the great forests from which "Norway pine" timber is chiefly derived are on the comparatively lower slopes of the southeastern dales; in the highest situations it dwindles to a mere bush. It furnishes the yellow deal of the Baltic and Norway. In Germany, both on the mountains and the sandy plains, woods of "kiefer" are frequent and widely spread, while vast forests in Russia and Poland are chiefly composed of this species; in many northern habitats it is associated with the spruce and birch. In Asia it abounds in Siberia and on the mountains of the Amur region; on the European Alps it occurs at a height of 5000 ft., and on the Pyrenees it is found at still higher elevations; on the northern side of Etna it is said to grow at above 7000 ft. In Britain natural forests of Scotch fir of any extent are only now found in the Highlands, chiefly on the declivities of the Grampians. In former ages the tree covered, a large portion of the more northern part of the island, as well as of Ireland; the numerous trunks found everywhere in the mosses and peat-bogs

depends greatly on the soil and position in which the trees are grown: the dry slopes of granitic or gneissic mountains, or the deep well-drained sandy gravels of the lower country seem to answer equally well; but on clay or wet peat the tree rarely

Large quantities of turpentine are extracted from this pine in Sweden and Russia by removing a strip of bark, terminating below in a deep notch cut in the wood, into which the turpentine runs, and from which it is scooped as it accumulates; but the product is not equal to that of the silver fir and other species. Tar is prepared largely from *P. sylvestris*; it is chiefly obtained from the roots, which, mingled with a few logs, are arranged in a conical or funnel-shaped hollow made on the steep side of a hill or bank; after filling up, the whole is covered with turf and fired at the top, when the tar exudes slowly and runs into an iron vessel placed below, from the spout of which it is conveyed into barrels. Most of the so-called Stockholm tar is thus prepared, chiefly in the province of Bothnia.

Closely allied to the Scotch pine, and perhaps to be regarded as a mere alpine form of that species, is the dwarf *P. montana* (or *P. abies* f. montana). In Germany, it is known under the name of *Perlandra montana*—a recumbent bush, generally only a few feet high, but with long zigzag stems, that root occasionally at the knee-like bends where they rest upon the ground. The foliage much resembles that of the *S. sylvestris*; the heart-wood is of a brownish-; t. In species are smaller but similar in form. Abounding on the higher slopes of the Bavarian and Tripolsec Alps, it is a favourite shelter for the chamois; the hunters call it the "latschen," from its recumbent straggling form. It is of little value for timber, and is easily distinguished from *P. sylvestris* by its smaller leaves which are covered with a light and white fringe. It is found in the shape of a clump, in the interior of Germany, being probably obtained from the Carpathians.

The red pine of Canada and New England (so-called from the colour of its bark), *P. resinosa*, is a tree of considerable size, sometimes attaining the dimensions of *P. sylvestris*. Occasionally it approaches the latter in the thickness of its trunks; but the more usual size is from 4 ft. to 6 ft. in diameter; it is also found in Maine 4 ft. in diameter. A sandy soil seems to suit it best, and the quality of the wood probably much depends on its place of growth. Red pines abound in Nova Scotia and Newfoundland, and are generally found on the shores of lakes, and in the sparsely wooded parts of the interior of the continent; it rarely forms extensive woods, but grows chiefly in clumps among other trees, at least in its more southern habitats. Nearly allied is *P. Banksiana*, the grey or Labrador pine, sometimes confused with *P. resinosa* on account of its smaller size. Among the most northerly representative of the genus in America, and is chiefly remarkable for its much recurved and twisted cones, about 2 in. long. The trunks are too small to be of great economic value, but the wood is used in the manufacture of various articles.

*Laricio*, the Corsican pine, is one of the noblest trees of this group, growing to a height of 100 or even 150 ft., with a straight trunk and branches in regular whorls, forming in large trees a columnar head; it is found from Capo Coda Cavallo to Messina, and is considered by some as a separate species; it occurs on the higher mountains of Cyprus. The tree is of very rapid growth, but produces good timber, much used in southern dockyards, and very durable, though less strong than that of *Pinus sylvestris*. It occurs in the mountains of southern France, but has been planted with success on the drift-sands of the Bay of Biscay, though it does not bear the full force of the sea-blast as well as the pinaster. In England it grows well in sheltered situations, and yields excellent timber.

The black pine, *P. austriaca*, generally now regarded as a variety of *P. Laricio*, derives its name from the extreme depth of its foliage tints—the sharp, rigid, rather long leaves of a dark green hue. It is the harder and more important of the European species, and is very resistant to the attack of the blight. The light, and in southern France it has been planted with success on the drift-sands of the Bay of Biscay, though it does not bear the full force of the sea-blast as well as the pinaster. In England it grows well in sheltered situations, and yields excellent timber.

The pine is an important tree in the economy of the northern nations of Europe. In Scandinavia and Russia houses are chiefly constructed of its timber; and log-huts are made of the smaller trunks and lined and roofed with the bark. The inner bark is twisted into ropes, and, like that of the spruce, is kiln dried, ground up, and mixed with meal in times of scarcity; in Kamchatka it is macerated in water, then pounded, and made into a kind of substitute for bread without any admixture of flour. In recent days the fibre of the leaves has been extracted in some quantity and applied to textile purposes under the name of *waldwolle*, both in Germany and Sweden. It is prepared by boiling the needles in a solution of soda to remove the resin, which process loosens the fibre and renders its separation easy; it has some resemblance to coarse wool, and is spun and woven into blankets and garments that are said to be warm and durable; it is also used for stuffing cushions; an essential oil, obtained by a previous distillation of the leaves, has medicinal virtues attributed to it by some German practitioners.
species. *P. halepensis*, another Mediterranean form, is valued for its timber, which is white with a fine grain, and resinous products.

*Pinaster*, the cluster pine or pinaster, is an important species from its vigorous growth in the sand-drifts of the coast, for the pulp it yields has been highly successful than any other tree, especially on the dunes of the Bay of Biscay. Growing to a height of from 30 to 80 ft., the deeply-furrowed trunk occasionally reaches a diameter of 3 ft. or more at the base. In most sandy situations, the trunk, when mature, is covered gradually, a form that enables the long tap-roots to withstand better the strain of the sea gale; when once established, the tree is rarely overthrown even on the loose sand. The branches converge horizontally, with tufts of tufted green leaves, giving a massive rounded outline to the tree; the ovate cones are from 4 to 6 in. long, of a light shining brown hue, with thick scales terminating in a pyramidal apex; they are arranged around the branches in the radiating clusters that give name to the tree. The pinaster has been largely planted on sandy soils along the Mediterranean from Spain to the Levant. On the drift-sands of France, especially in the Gironde, forests have been formed mainly of this pine; the seeds, sown at first under proper shelter and later transferred to the open ground, have a very high rate of germination, and the trees vegetate rapidly in the sea-sand, and the trees thus raised have, by their wind-drifted seed, covered much of the former desert of the Landes with an evergreen wood. These forests of pinaster, after the manner of the true pines, produce turpentine, which, like that of the true pines, is derived from the resin, but the supply fails until the trees are exhausted; the trunks are then felled and used in the manufacture of charcoal and lamp black; much tar and pitch is also obtained from these pinaster forests. In England, the Pinaster, which has been naturalized near the sea, and has become naturalized in Purbeck and other wild tracts in the southern counties, but the summer heat is too small to permit of its resinous products acquiring any value; the soft needles, though perishable in the natural state, have been used for railway sleepers after saturation with creosote or preservative solutions.

*P. pinea* is the stone pine of Italy; its spreading rounded canopy of dark-brown needles, tufted in the lower parts of the tree, forms a striking feature of the landscape in that country, as well as in some other Mediterranean lands. The beautiful reddish-brown shining cones, roundly ovate in shape, with pyramidal sheaths, are prized by the Chinese for their edible nut-like seeds, which are still used as an article of food or dessert. They do not ripen until the fourth year, and are kept in the cone until required, as their abundant oil soon turns rancid.

The tree has been naturalized in many warm countries, especially in China; in England it seldom attains any large size, the deficient summer heat prevents the wood from maturing; but trees occur occasionally in plantations 20 or 30 ft. in height; the wood, though soft and deficient in the heartwood, gives heartwood to the timber trade.

*P. radiata*, the native of Australia, is valued by the southern Californians for its cabinet maker's timber, its fineness of grain, and the ease with which it is worked.

*P. maha*, the yellow pine of the northern and middle states of America, is similarly called to the three-leaved section, but the leaves are mostly in pairs. It is a tree of large size, often attaining a height of 70 ft. and upwards, though rarely more than 2 ft. in diameter at the root; the lower branches spread horizontally, the upper branches upwards, so that the trees present the three-occasional aspect of a spruce, hence it is called in some districts the "spruce-pine."

The leaves are long, slender, and of a bluish-green hue; the pendant cones are about 15 in. long, with a slender point to each scale, and the bark is rough. The heartwood is light yellow, and is the largest tree of the genus; the heartwood being very durable is largely employed in ship-building and for house timber, being nearly equal to that of *P. sylvestris*; large quantities are exported to British India, and to New York and London.

The three-leaved group includes several of the most valuable trees of America: among them is *P. rigida*, the pitch pine of the northern states, from 50 to 80 ft. in height, the leaves are occasionally 3 in. in diameter; the short dark-green leaves are in thick tufts, contrasting with the pale yellowish, usually clustered cones, the scales of which are furnished with small curved spines. The earthy or heartwood is of inferior quality and of little value except for fuel, for which the pitch-pine is highly prized; on drier ground the tree is fine from the numerous knots. Large quantities of tar and pitch are obtained from this species. The tree is one of the few that will flourish in salt-marshes.

*P. palustris* (or *P. australis*) is the "Georgia pitch pine," or yellow pine of the southern states; it abounds on the sandy soils that cover so much of Georgia, the Carolinas, and Florida, and on the sandy drifts of the coast. On dry land it is inferior and of small growth, whilst on moist ground it is extremely abundant, and has obtained the name of "Georgia pine" by the settlers of the new world; it is occasionally planted by the gardeners in this country on soils of a warm and damp nature, and is a beautiful and hardy species. The leaves are tufted, and in the dry form, in open glades the lower boughs often touching the ground, but in old age it acquires a wide almost cedar-like top. The light bluish-green foliage is somewhat lax, very dense in young trees; the cones are long and rather curved, with thin smooth scales. The heartwood is light yellow, and is the largest tree of the genus; it is durable for indoor use, especially when protected by paint, but when exposed to moist air it rapidly decays, and it is very liable to dry rot; it is said to be best when grown on sandy soils. Immense quantities of tar and pitch are obtained from this species, which is an exceptionally-worked grain rendering it a favourite wood for the house-carpeter and joiner; it weighs about 42 lb per cubic foot. In England where it is generally known as the "Weymouth pine," it succeeds well on deep light soils when we demanding trees have attacked the best. It is also abundant on the sandy drifts and inwards in British plantations; but it is apt to be infested with American blight (*Erysoma*). In northern Germany it also grows well. The climate of Scotland
PINE-APPLE—PINERO

625

appears less suitable for it, probably from the want of summer heat, and it can hardly be recommended for British planting otherwise than for ornamental purposes.

Nearer approaching this is P. excelsa, the Bhotan pine, which differs chiefly in its longer cones and drooping glious foliage. It is found in Kumaon and Bhotan and on some of the Nepal ranges, but does not grow in the moist climate of the Sikkim Himalayas; it is found at a height of 7000 to 12,000 ft., and attains large dimensions, its wood is highly resinous, and its cones to be durable; great quantities of a white clear turpentine exude from the branches when injured. The Bhotan pine is quite hardy in southern England, and has been largely planted of late as an ornamental tree.

P. andina, the giant pine or sugar pine of California, is the largest of the genus, rising to the height of 200 ft., with a trunk 20 to 30 ft. in girth, and, if it is, occasionally attaining much larger dimensions. The head is of a pyramid form, the lower branches drooping; those of Norway spruce; its foliage is of a light bright green colour. The pendent cones are very large, sometimes 18 in. long and 4 in. in diameter, with large nut-like seeds, which, pounded and baked, are eaten by the Indians. The tree abounds in some sandy districts, but more generally occurs singly or in small groups dispersed through the woods, attaining its greatest dimensions in light soils. The wood is soft and nearly white, but contains much resin, which when fire has run through the half-burnt condition has given the common name to the tree; the wood seems to be formed slowly; from its smooth grain it is valued for indoor carpentry; the saccharine burnt resin is used as a laxative in California.

P. Cembra is the stone pine of Siberia and central Europe. It abounds on the Alps, the Carpathians and the siberian ranges, in Switzerland being found at an altitude of 4000 to 6000 ft. It is a strictly conic tree, with grey bark and whorls of horizontal branches giving a column-conical outline; the leaves are short, rigid and glaucous; the cones, oblong and rather pointed upwards, grow only near the top of the tree, and ripen in the second autumn; the scales are similar to those of P. Pinea, and are eaten both on the Alps and by the inhabitants of Siberia; a fine oil is expressed from them which is used both for food and in lamps, but, like that of the Italian pine, it soon turns rancid. The growth of P. Cembra is slow, and the wood is of remarkably even grain, and is employed by the Swiss wood-carvers in preference to any other. The Cembra is the "zirbel" or "zirbel-kiefer", of the Germans, and is known locally in Switzerland as the "arctic", "albies", and "arve..."

P. occidentalis, a five-leaved pine with pale-green foliage and small ovate cones, is found on the high mountains of Santo Domingo and Cuba. Many members of the group occur on the Mexican isthmus, one of which, P. tenbroeckis, produces edible seeds; another, P. Montezuma, is a valuable timber tree. P. Asacabrul, the common white pine of Mexico, spread southwards on to the mountains of Guatemala, it is a large tree with glauous foliage like P. Sylvestris, and yields a valuable resin. P. pflabola and P. mexicana, the pines of Central America, are remarkable for the extreme length of their leaves; the former is said to attain a large size.

(C. P. J.)

PINE-APPLE. The pine-apple so called consists in reality of the inflorescence of the plant, the originally separate flowers of which, together with the bracts supporting them, become fleshy and consolidated into one mass. The swelling and fusion of the tissues take place after the process of fertilization and it may be that the richly perfumed succulent mass is an aid in the distribution of seeds by affording food to the animals and birds feeding on the highly cultivated pines; however, it frequently happens that the seeds do not ripen properly. The pine, Ananas sativus, is a member of the natural order Bromeliaceae, of tropical American origin, where it is widely spread; and it is now naturalized in the tropical regions of the Old World.

Evelyn in his Diary mentions tasting a pine-apple from Barbados at the table of Charles I., and this is we believe the first mention of the fruit in English literature. A picture, of which a copy may be seen at the rooms of the Royal Horticultural Society of London, represents the royal gardener, Mr Rose, presenting on bended knee the first pine-apple grown in Britain, and it is surmised that this may have been grown from the "suckers" of the fruit above alluded to by Evelyn, though it is generally considered that the pine was not cultivated in England till 1716. For many years pine-apples were cultivated in large private gardens, but owing to the great developments in culture in the West Indies, the Azores, Canary Islands, &c., they are no longer cultivated in Britain or Europe.

PINE BLUFF, a city and the county-seat of Jefferson county, Arkansas. U.S.A., situated at an altitude of about 200 ft. in the alluvial bottoms of the Arkansas river, about 107 m. from its mouth, and about 42 m. S. by E. of Little Rock. Pep. (1926), 15,102. It has an active river trade with St Louis, Memphis and New Orleans, and five railway outlets—the Missouri Pacific and its branch, the Pine Bluff & Western, and the St Louis South-Western and its two branches, the Pine Bluff & Arkansas River and the Altheimer. The city has many schools, and a business college, the state normal school for NEGROES, and the University, endowed by Joseph Merrill of Pine Bluff with $100,000. Large quantities of cotton and lumber are shipped from the city. Among the manufactures are cotton-seed oil, lumber and staves, and furniture. Pine Bluff has shops of the St Louis South-Western railway. The city's factory products were valued at $2,693,242 in 1905, an increase of 94% over their value in 1900. Pine Bluff was laid out in 1832 and chartered as a city in 1885.

Pine-apple (Ananas sativus) much reduced.

PINEL, PHILIPPE (1745-1826), French physician, was born at the chateau of Rascas, Saint-André, in the department of Tarn, France, on the 20th of April 1745. He studied at Laval and afterwards at the university of Toulouse, where he took his doctor's degree in 1773. From Montpellier he removed in 1778 to Paris, where he was chiefly in literary work connected with his profession. His first publication was a French translation of William Cullen's Nosology (1785); it was followed by an edition of the works of G. Baglivi (1788), and in 1791 he published a Traité médicale-philosophique de l'albinisme mentale. In 1792 he became head physician of the Bicêtre, and two years afterwards he received the corresponding appointment at the Salpêtrière, where he began to deliver a course of clinical lectures; these formed the basis of his Nosographie philosophique (1798; 6th ed., 1818), which was further developed in La Médecine clinique (1802). Pinel was made a member of the Institute in 1803, and soon afterwards was appointed professor of pathology in the École de Médecine. His fame rests entirely upon the fact that he was among the first to introduce the humane treatment of the insane. He died at Paris on the 26th of October 1826.

PINERO, SIR ARTHUR WING (1855-1911), English dramatist, was born in London on the 24th of May 1855, the son of John Daniel Pitner, a Jewish solicitor, whose family was of Portuguese origin, long established in London. A. W. Piner was engaged in 1874 as an actor at the Theatre Royal, Edinburgh, and came to London in 1876, to play at the Globe Theatre. Later in the year he joined the Lyceum company, of which he remained a member for five years. The first piece of his to see the footlights
was £200 a year, played in October 1877 at the Globe Theatre for the benefit of Mr F. H. Macklin. The first play to make hit was The Money Spinner (Theatre Royal, Manchester, Nov. 1880); but in The Squire (St James's Theatre, Dec. 1881) he attempted serious drama, and gave promise of the qualities of his later work. In 1883 and 1884 Pinero produced seven pieces, but the most important of his works at this period were the successful farces produced at the Court Theatre: The Magistrate (March 1885), which ran for more than a year; The Schoolmistress (March 1886); Dandy Dick (Jan. 1887), revived in February 1900; The Cabinet Minister (April 1890), and The Amazons (March 1893). Two comedies of sentiment, Sweet Lavender (Terry's, March 1888) and The Weaker Sex (Theatre Royal, Manchester, Sept. 1888), met with success, and Sweet Lavender has enjoyed numerous revivals. With The Prodigate (Garrick, April 1889) he returned to the serious drama which he had already touched on in The Squire. Out of deference to the wishes of John Hare the play was fitted with the conventional "happy ending," but the original dénouement was restored, with great advantage to the unity of the play, in the printed version. The Second Mrs Tanqueray (St James's, May 27, 1893) dealt with the question propounded in The Fencing Master, and aroused great discussion, and placed Pinero in the front rank of living dramatists (see Drama: Recent English). It was translated into French, German and Italian, and the part of Paula Tanqueray, created in the first place by Mrs Patrick Campbell, attracted many actresses, among others Eleonora Duse. His later plays were The Notorious Mrs Ebbsmith (Garrick, March 13, 1895), The Benefit of the Doubt (Comedy, Oct. 1895), The Princess and the Butterfly (St James's, April 7, 1897), Treason of the Wells (Court, Jan. 30, 1898), The Gay Lord Quex (Globe, April 8, 1899), Iris (Garrick, Sept. 21, 1901), Letty (Duke of York's, Oct. 8, 1903), A Wife Without a Smile (Wyndham's, Oct. 9, 1904), His House in Order (St James's, Feb. 1, 1906), The Thunderbolt (St James's, May 9, 1908) and Mid-Channel (St James's, Sept. 2, 1909). Pinero was knighted in 1900.

His Plays (11 vols. 1891-1896) have prefaces by M. C. Salaman. See also H. Hamilton Fyfe, A. W. Pinero (1902).

**Pinerolo** [Pineroli], a city and episcopal see of Piedmont, Italy, in the province of Turin, Pop. (1901), 12,608 (town), 18,039 (commune). It is built on a hill-side just above the valleys of the Chisone and the Lemina, at a height of 1324 ft. above the sea, 24 m. by rail S.W. of Turin. The railway goes on to Torre Pellice; and steam tramways run from Pinerolo to Perosa, and to Cavour and Saluzzo. Till 1666 it was strongly fortified with a citadel on Santa Brigida, a castle on S. Maurizio, and city walls constructed by Thomas I. of Savoy. It has a cathedral (St Donatus), the palace of the princes of Acaia and other buildings of some interest. Cotton, silk, wool and hemp are among the local manufactures.

Pinerolo was bestowed on the bishops of Turin by Otto III. in 996; but in 1078 the countess Adelaide made it over to the Benedictine abbey of Santa Maria, in whose possession it remained till 1159. Thomas I. of Savoy captured the castle in 1188, and in 1246 the commune formally recognized the supremacy of Savoy. Passing in 1205 into the hands of Philip, son of Thomas III., Pinerolo became his residence and capital, a duty from which it retained under Amadeus VIII. of Savoy; Francis I. of France obtained possession of the town in descent into Italy, but Emmanuel Philibert received it back from Henry III. in 1574. A second occupation by the French occurred under Cardinal Richelieu; the French language was imposed on the people, great fortifications were constructed, and the fortress (Pignerol) was used as a state prison for such men as Fouquet, De Caumont and the Man with the Iron Mask (see Iron Mask). Victor Amadeus bombarded the place in 1693, and ultimately compelled Louis XIV. to relinquish his hold on it; but before the withdrawal of the French troops the defences were demolished. In 1748 the town was made a bishop's see.

**Pinerol—Pink**

**PINEROLO—PINK**, a botanical term for flowers which occur in two forms, one of which shows the stigma at the mouth of the corolla, as in the lining of the ovary, and thenceforth with thorn-eyed. **PING-PONG, or Table-Tennis**, a miniature variety of lawn-tennis played on a table, which may be of any size not less than 5½ ft. long by 3 ft. broad. Various attempts were made to adapt lawn-tennis to the house, but the real popularity of the game began when, near the close of the 19th century, celluloid balls were introduced, and the game was called ping-pong from the sound of the balls as they were struck by the racket or rebounded from the table. In 1900 the ball was improved and made heavier, and for the next two years ping-pong enjoyed a popularity never before attained by a game in so short a time, not only in Great Britain but in France, the British Colonies and America.

Two leagues were formed, the "Table-Tennis Association" and the "Ping-Pong Association," whose laws were practically identical. The regular tournament table is 9 ft. long by 5½ ft. broad, and the net is a little less than 7 in. high. The balls, which are of hollow celluloid, are about ¾ in. in diameter. The racket has a blade, shaped like a lawn-tennis racket, about 6 in. long and a handle long enough to grasp comfortably, all in one piece. Rackets are made either wholly of wood covered with rubber or celluloid or partly of wood and partly of rubber; others have with veilum or some other material. The table was at first marked out in courts, but is now plain. It should be unpolished and stained. In serving, a player must stand directly behind his end of the table and use an underhand motion only. The ball must clear the net and strike the table anywhere on the other side. The game is then continued until the ball misses the table or fails to pass over the net. Only one service is allowed, except in case of a let. The scoring is the same as in lawn-tennis.

See Ping-Pong, by Arnold Parker (London, 1902); Table Tennis, by A. Sinclair (London, 1902).

**Pink**, in botany, the common name corresponding to a genus of Caryophyllaceae, the Dianthus of botanists. It is characterized by the presence of simple leaves borne in pairs at the thickened nodes, flowers terminating the axis and having a tubular calyx surrounded by a number of overlapping bracts, a showy corolla of five free long-stalked petals, ten stamens proceeding, together with the petals, from a short stalk supporting the ovary, which contains a single cavity. The pericarp is soft and pliable, like one-chambered many-seeded capsule which opens at the apex by four curts or valves. The species are herbaceous perennials of low stature, often with very showy flowers. They are natives chiefly of southern Europe and the Mediterranean region, a few being found in temperate Asia and South Africa. Four species are wild in Britain. Of these, D. armeria, Deptford pink and D. deltoïdes, maiden pink, are generally distributed, D. caesius, Cheddar pink, occurs only on the limestone rocks at Cheddar. Two others, D. plumarius and D. caryophyllus, are more or less naturalized, and are interesting as being the originals of the pinks and of the carnations and picotees of English gardens. Garden pinks are derivatives from Dianthus plumarius, a native of central Europe, with leaves rough at the edges, and with rose-coloured or purplish flowers. The use of "pink" for a colour is taken from the name of the plant.¹

The pink is a favourite garden flower of hardy constitution. It has been in cultivation in England since 1629, and is a great favourite with florists, those varieties being preferred which

¹ The etymology of "pink" is disputed; it may be connected with "pink" (apparently a naturalized form of "pick") properly to prick or punch holes in material for the purpose of floral ornament, later, to scallop or cut a pattern in the edge of the material. The flower has jagged edges to the petals, but the name occurs in the 17th century, and the later meaning, "to scallop," not till the 19th. Others connect with "pink," half slipped on the side as in "plumbeous Baccus, with pinke ye" (Shakespeare, [*All’s Well That Ends Well*, 1. ii. 121]); this word is seen in Dutch *pinken*, to blink, shut the eyes, and may be connected with "pink." The French name for the flower, *oeillet*, little eye, may point to this derivation. The disease of horses, known as "pink's eye," a contagious influenza, is so-called from the colour of the - islated conjunctiva, a symptom of the affection.
PINKERTON, A.—PINKNEY 627

have the margin of the petals entire, and which are well marked in the center with bright crimson or dark purple. Its glossy and glaucous foliage is much like that of the carnation, but the whole plant is smaller and more tufted. Pinks require a free loamy soil deeply trenchled, and well enriched with cow-dung. They are readily increased by cuttings (pipings), by layers and by seed. Cuttings and layers should be taken as early in July as practicable. The former should be rooted in a cold frame or in a shady spot out of doors. When rooted, which will be about August, they should be planted 4 in. apart in a nursery bed, where they may remain till the latter part of September or the early part of October. The chief attention required during winter is to press them down firmly should they become lifted by frosts, and in spring the ground should be frequently stirred and kept free from weeds. The pink is raised from seeds, not only to obtain new varieties, but to keep up a race of vigorous-growing sorts. The seeds may be sown in March or April in pots in a warm frame, and the young plants be pricked off into boxes and sheltered in a cold frame. They should be planted out in the early part of the summer in nursery beds, in which, if they have been spaded, they may remain from March to May. Some may be transplanted to a blooming bed in September or the early part of October; in either case they will bloom the following summer. These will grow in any good garden soil, but the richer it is the better.

The border varieties are useful for forcing during the early spring months. These are propagated from early pipings and grown in nursery beds, being taken up in October, potted in a rich loamy compost, and wintered in a cold pit till required for the forcing house.

The Carnation (q.v.) and Picotee are modifications of Diathus Caryophyllus, the Clove Pink. This is a native of Europe, growing on rocks in the south, but in the north usually found on old walls. Its occurrence in England on some old houses, and near Harford, as at Rochester, is supposed by Canon Ellacombe to indicate its introduction by the Normans; in any case the plant grows in similar situations in Normandy. The carnation includes those flowers, small spotted or striped lengthwise—the petals which are those in which the petals have a narrow band of colour along the edge, the remainder of the petal being free from stripes or blotches. These by the old writers were called "gillyflowers." The Sweet William of gardens is a product from Diathus barbatus. The Sweet William, Statice (Amorium balloon), is a member of the natural order Plumbagineae; it is a widely distributed plant found on rocky and stony sea-shores and on lofty mountains. There are many improved varieties of it now in cultivation, one with almost pure white flowers.

PINKERTON, ALLAN (1819-1884), American detective, was born in Glasgow, Scotland, on the 25th of August 1819. His father, a sergeant of the Glasgow municipal police, died in 1829 of small-pox, and left his widow with a family of four children. In 1832 Allan emigrated to Chicago, Illinois. In 1833 he purchased a farm in Dundee, Kane county, Illinois, where he established a cooperage business. Here he ran down a gang of counterfeiters, and he was appointed a deputy-sheriff of Kane county in 1846 and immediately afterwards of Cook county, with headquarters in Chicago. There he organized a force of detectives to capture thieves who were stealing railway property, and this organization developed in 1832 into Pinkerton's National Detective Agency, of which he took sole charge in 1853. He was especially successful in capturing thieves who stole large amounts from express companies. In 1866 his agency captured the principals in the theft of $700,000 from Adams Express Company sales on a train of the New York, New Haven & Hartford railway, and recovered all but about $12,000 of the stolen money. In February 1861 Pinkerton found evidence of a plot to assassinate President-elect Lincoln upon his arrival in Baltimore on his way to Washington; as a result, Lincoln passed through Baltimore at an early hour in the morning without stopping. In April 1861 Pinkerton, on the suggestion of General George B. McClellan, organized a system of obtaining military information in the Southern states. From this system he developed the Federal secret service, of which he was in charge throughout the war, under the assumed name of Major E. J. Allen. One of his detectives, James McParlan, in 1873-1876 lived among the Molly Maguires (q.v.) in Pennsylvania and secured evidence which led to the breaking up of the organization. In 1889 Pinkerton suffered a partial stroke of paralysis, and thereafter the management of the detective agency devolved chiefly upon his sons, William Allan (b. 1846) and Robert (1845-1907). He died in Chicago on the 1st of July 1884.

PINKERTON, JOHN (1758-1826), Scottish archaeologist, numismatist and author, was born at Edinburgh on the 17th of February 1758. He was articled as a law clerk in Edinburgh, and his Elegy on Craigmillar Castle (1776) was printed during his clerkship. In 1781 he removed to London to devote himself more exclusively to literature. The following year he published Thirty Years a Detective (1876), The Molly Maguires and the Detectives (1877), The Spy of the Rebellion (1883), in which he gave his version of President-elect Lincoln's journey to Washington; and Thirty Years a Detective (1884).

PINKERTON, JOHN (1758-1826), Scottish archaeologist, numismatist and author, was born at Edinburgh on the 17th of February 1758. He was articled as a law clerk in Edinburgh, and his Elegy on Craigmillar Castle (1776) was printed during his clerkship. or condemnations," and during this time adjusted on behalf of Maryland a claim of the state to stock to the Bank of England. In May 1806, with James Monroe, then minister to London, he was commissioned to treat with the British government concerning the capture of neutral ships in time of war; in 1807-1811, after Monroe's return to America, he was resident minister in London. He was elected to the Maryland senate in September 1811, and from December 1811 to January 1814 was attorney-general of the United States. In August 1814 he was wounded at Bladensburg. He served in the National House of Represent-atives in January-April 1816, and in 1816-1818 was minister plenipotentiary to Russia and special minister to Naples, where he attempted to secure indemnity for the losses to American merchants by seizure and confiscation during the rule of Murat in 1809. From 1820 until his death, at Washington, on the 25th of February 1822, he was a member of the United States Senate. He was a member of the conference committee on the bill for the admission of Maine and Missouri, which in its final form embodied what is known as the Missouri Compromise. Pinkney was a remarkably able lawyer and an orator of the old school.

See The Life of William Pinkney (New York 1853) by his nephew, William Pinkney (1810-1883), who was President Episcopal bishop of Virginia in 1879-1883; and Henry Wheaton, Some Account of the Life, Writings, and Speeches of William Pinkney (New York, 1839.

PINNACE, the name of two types of vessel or boat, one a light sailing vessel with two schooner-rigged masts, the other a heavy eight-oared man-of-war's boat. The word is usually referred to Lat. *pinus*, pine, but this derivation is at variance with the earlier form "spinae."

PINCALL (from Lat. *pinaculum*, a little feather, *pinna*; the Gr. *πετρεία*, diminutive of *πτερός*, wing, is also used in this sense), an architectural ornament originally forming the cap or crown of a buttress or small turret, but afterwards used on parapets at the corners of towers and in many other situations. Some writers have stated that there were no pinnacles in the Romanesque styles, but conical caps to circular buttresses, with finial terminations, are not uncommon in France at very early periods. Viollet-le-Duc gives examples from St Germer and St Remi, and there is one of similar form at the west front of Rochester Cathedral. In the 12th-century Romanesque two examples have been cited, one from Bredon in Worcestershire, and the other from Gloucester Cathedral. In the last-named a large angle rung up, forming a sort of square turret, and crowned with a pyramidal cap, very much like those of the next period, the Early English. In this and the following styles the pinnacle seems generally to have had its appropriate uses. It was a weight to counteract the thrust of the vaults, particularly where there were flying buttresses; it stopped the tendency to slip of the stone copings of the gables, and counterpoised the thrust of spires; it formed a pier to steady the elegant perforated parapets of later periods; and in France especially served to counterbalance the weight of overhanging corbel tables, huge gargoyles, &c. In the Early English period the small buttresses frequently finished with gables, and the more important with pinnacles supported with clustered shafts. At this period the pinnacles were often supported on these shafts alone, and were open below; and in larger work in this and the subsequent periods they frequently form niches and contain statues. About the Transition and during the Decorated period, the different faces above the angle shafts often finish with gables. Those of the last of the Decorated period are much richer, and are generally decorated with crockets and finials, and sometimes with balls and flowers. Very fine groups are found at Beverley Minster and at the rise of the spire of St Mary's, Oxford. Perpendicular pinnacles differ but little from Decorated, except that the crockets and finials are of later character. They are also often set angle-ways, particularly on parapets, and the shafts are panelled. In France pinnacles, like spires, seem to have been in use earlier than in England. There are small pinnacles at the angles of the tower in the abbey of Staines. At Roulet there are pinnacles in a similar position, each composed of four small shafts, with caps and bases surmounted with small pyramidal spires. In all these examples the towers have semi-circular-headed windows.

PINNACE—PINNACLE

PINNACE, or Pinochle (Ger. *Pinochel* or *Pinochel*, of uncertain etymology), a game of cards probably invented by Germans in the United States about the middle of the 19th century. It is now extensively played throughout the United States and Canada, and has almost entirely usurped the place of the older game in America. Pinochle may be played by two, three or four persons. Two packs, from which all cards below the nines have been deleted, are shuffled together, forming one pack of 48 cards. The object of the game is to make 1000 points. The cards rank as follows: ace 11, ten 10, king 4, queen 3, knave 2. The nine counts nothing unless it be turned for trumps, when it scores 10. The last trick scores 10. The term "to meld" (Ger. *melden*, to announce), as used in pinochle, means "to declare." "Melds" are combinations which are declared during the play of the hands. They are of three classes: (1) "marriages" and "sequences," (2) "pinnacles," and (3) "fours." The "mels" of the first class are as follows: "marriage" (king and queen of any plain suit), 20; "royal marriage" (king and queen of trumps), 40; "sequence" (the five highest trump cards), 150. In the second class the "melds" are: a "double pinnace" (queen of spades and knave of diamonds), 40; "triple pinnace" (both queens of spades and diamonds), 90; "grand pinnace" (king and queen of spades and knave of diamonds), 80; this "meld" is not often played in America. Of the third class the "melds" are: four aces of different suits, 100; four kings of different suits, 80; four queens of different suits, 60; four knaves of different suits, 40; eight aces, 1000; eight kings, 800; eight queens, 600; eight knaves, 400.

In single pinochle (two players) each player receives twelve cards, four at a time, the twenty-fifth being turned up beside the stock for trumps. The non-dealer leads a card, to which the dealer plays two of his hand, and the winner takes the trick. The dealer then takes the last trump card on the table and adds it to his stock. The winner of the trick of the same suit has the option of taking the last card on the table and adding it to his stock. The winner of the last trick of the same suit holds the trump cards and can play them in any order, but must always play them if it wins the trick. The winner of the last trick of the same suit is the winner of the hand and scores the total number of points in the hand. The hand is scored by counters or on a cribbage-board.
In three-handed pinochle the "melds" are exposed before a card is played, and no player may "meld" after he has played to the first trick. A rule is sometimes made that an overlooked combination may be scored by the other players. Four-handed pinochle is played either with partners or each player for himself.

PINZK, a town of Russia, in the government of Minsk, at the confluence of the Strumen and Pina rivers, 196 m. N.W. by rail of Minsk. Pop., 27,038, two-thirds being Jews. The town carries on considerable trade, due to the navigable river, Pina, which connects it with the fertile regions in the basin of the Dnieper, and, by means of the Dnieper-and-Bug canal, with Poland and Prussia, while the Oginsky canal connects it with the basin of the Niemen. Pottery, leather, oil, soap and beer are the chief products of the local industries. The draining of the marshes around Pinzsk was begun by the government in 1872, and by 1897 8,000,000 acres had been drained at an average cost of about 60 cents per acre. Pinzsk (Pinsk) is first mentioned in 1097 as a town belonging to Svitapolok, prince of Kiev. In 1132 it formed part of the Minsk principality. After the Mongol invasion of 1230–42 it became the chief town of a separate principality, and continued to be so until the end of the 13th century. In 1320 it was annexed to Lithuania, in 1560, after the union of Lithuania with Poland, it was chief town of the province of Brest. During the rebellion of the Cossack chief, Bogdan Chmielnicki (1649), the Poles took it by assault, killing 14,000 persons and burning 5000 houses. Eight years later the town was burned by the Russians. Charles XII. took it in 1706, and burned the town with its suburbs. Pinzsk was annexed to Russia in 1795.

PINSUTI, CIRO (1829–1888), Anglo-Italian composer, was born at Siena, and was educated in music, for a career as a pianist, partly in London and partly at Bologna, where he was a pupil of Rossini. From 1848 he made his home in England, where he became a teacher of singing, and in 1856 he was made a professor at the Academy of Music in London. He became well known as a composer of numerous favourite songs and part-songs, as well as of three operas brought out in Italy, and it is by the former that he is still remembered.

PINZ, (derived probably through Spanish, from Lat. pinio, picio, a painted or marked vessel), a liquid measure of capacity, equivalent to ⅝ of a gallon. The imperial British pint = ⅕ of a litre, 34+66 cub. in. The United States standard pint = ⅔ of a litre, 28.3 cub. in. The word appears in French as pint for a liquid measure as early as the 13th century.

PINTO, ANIBAL (1829–1884), Chilean painter, was born at Santiago, Chile. After a diplomatic training in the legation at Rome, he learned the practice of administration as intendente of Concepcion, and from 1871 to 1876 was minister of war and marine under Errázuriz. During his term of office as president (1876 to 1881) Pinto had to deal first with a severe financial crisis, and then to conduct the struggle with Peru and Bolivia, in which he displayed great coolness of judgment and devotion to duty.

PINTO, FERNAO MENDES (1500–1583), Portuguese adventurer, was born at Montemor-o-Velho, of poor and humble parents, and entered the service of a noble lady in Lisbon, being afterwards for two years page to the duke of Aveiro in Setubal. Desiring to try his fortune in the East, he embarked for India in 1537 in a fleet commanded by the son of Vasco da Gama, and for twenty-one years travelled, fought and traded in China, Tartary, Pegu and the neighbouring countries, sailing in every sea, while in 1542–1543 he was one of the first Europeans to visit Japan, where he introduced the musket. Though he was twice times a captain, and seventeen times sold into slavery, his gay and dauntless spirit brought him through every misfortune. He was soldier and sailor, merchant and doctor, missionary and ambassador; moreover, as the friend and traveling companion of St. Francis Xavier, he lent the army of the Indies the money with which to build the first Jesuit establishment in Japan. In January 1554 Mendes Pinto was in Goa, waiting for a ship to take him to Portugal, when he took a sudden resolution to enter the company of Jesus and devote a large part of the capital he had accumulated to the evangelization of Japan.

The viceroy appointed him ambassador to the king of Bungo in order to give the mission an official standing, and on the 18th of April he set sail with the provincial, Father Belchior Nunes. Pinto had to deal with weather and contrary winds, however, the mission did not reach Japan until July 1556, but the success of the mission represented notable service to the cause of Christianity and civilization. He departed from Japan on November 1556, and returned home bringing with him a large treasure.

See Christovão Ayres, Fernão Mendes Pinto (Lisbon, 1904).

He departed from Japan on November 1556, and returned home bringing with him a large treasure.

The Peregrination has gone through many editions subsequent to the first, several of which were published in 1905. Cartelho published excerpts in his Libraria classicas portugese with an interesting note as to Mendes Pinto's life and writings. Versions exist in German (3 editions), French (3 editions), Spanish (4 editions), and in English by Henry F. C. (1863, 1962) and abridged and illustrated, with introduction by Arminius W. (1863), and the chapters relating to Mendes Pinto's intercourse with, and the last days of, St. Francis Xavier, presumably as a concession to anti-Catholic prejudice.

PINTO—PINTURICCHIO

PINTO. The remarkable brown, black and blue spots of discoloration of the whole body met with endemically in Mexico, Panama, Colombia and Venezuela, and known under the name of "pinto" or "mal de los pintos," were first claimed by Gastambide (Presse med. Belge, 1881, Nos. 33-41) as due to the presence of a vegetable parasite, whose spores and even mycelial filaments may be detected among the deeper rows of cells of the rete mucosum. The disease appears to be one of the many forms of morbus visceris; but it is contagious, and is sometimes seen in the well-to-do. In some villages of the western districts of Tabasco (Mexico) it has been estimated that 9% of the inhabitants suffer from the pinto; M'Clelland says that in 1826 in the City of Mexico he saw a whole regiment of "pintados."

PINTURICCHIO (1454-1513). Italian painter, whose full name was Bernardino di Betti, the son of a citizen of Perugia, Benedetto or Betto di Blagio, was one of a very important group who inherited the artistic traditions and developed the style of the older Perugian painters, such as Bonfigli and Fiorenzo di Lorenzo. According to Vasari he was a pupil of Perugino; and so in one sense no doubt he was, but rather as a paid assistant than as an apprentice. The strong similarity both in design and methods of execution which runs through the works of this later Perugian school is very striking; paintings by Perugino, Pinturicchio, Signorelli, and Botticelli are often so much alike that they are often be mistaken one for the other. In most cases, especially in the execution of large frescoes, pupils and assistants had a large share in the work, either in enlarging the master's sketch to the full-sized cartoon, in transferring the cartoon to the wall, or in painting backgrounds, drapery and other accessories. After assisting Perugino in the execution of his frescoes in the Sistine Chapel, Pinturicchio was employed by various members of the Della Rovere family and others to decorate a whole series of chapels in the church of S. Maria del Popolo in Rome, where he appears to have worked from 1484, or earlier, to 1492 with little interruption. The earliest of these is an altarpiece of the "Adoration of the Shepherds," in the first chapel (from the west) on the south, built by Cardinal Domenico della Rovere; a portrait of the cardinal is introduced as the foremost of the kneeling shepherds. In the lunettes under the vault Pinturicchio painted small scenes from the life of St. Jerome. The frescoes which he painted in the next chapel, that built by Cardinal Innocenzo Cibo, were destroyed in 1709, when the chapel was rebuilt by Cardinal Alfonso Cibo. The second chapel on the south is that of Giov. della Rovere, Duke of Sora, nephew of Sforza, and brother of Giuliano, who was afterwards Pope Julius II. This contains a fine altarpiece of the "Madonna enthroned between Four Saints," and on the east side a very noble composition fresco of the "Assumption of the Virgin." The vault and its lunettes are richly decorated with small pictures of the life of the Virgin, surrounded by graceful arabesques; and the dado is covered with monochrome paintings of scenes from the lives of saints, medallions with prophets, and very graceful and powerfully drawn female figures in full length in which the influence of Signorelli may be traced. In the fourth chapel Pinturicchio painted the Four Latin Doctors in the lunettes of the vault. Most of these frescoes are considerably injured by damp, but happily have suffered little from restoration; the heads are painted with much minuteness of finish, and the whole of the pictures depend very largely for their effect on the final touchings a secco. The last paintings completed by Pinturicchio in this church were the frescoes on the vault over the retro-choir, a very rich and well-designed piece of decorative work, with main lines arranged to suit their surroundings in a very skilful way. In the centre is an octagonal panel of the coronation of the Virgin, and round it medallions of the Four Evangelists—the spaces between them being filled up by reclining figures of the Four Sibyls. On each pendant is a figure of one of the Four Doctors enthroned under a niched canopy. The bands which separate these pictures have elaborate arabesques on a gold ground, and the whole is painted with broad and effective touches, very telling when seen (as is necessarily the case) from a considerable distance below. No finer specimen of the decoration of a simple quadripartite vault can anywhere be seen.

In 1492 Pinturicchio was summoned to Orvieto, where he painted two Prophets and two of the Doctors in the duomo. In the following year he returned to Rome, and was employed by Pope Alexander VI. (Borgia) to decorate a suite of six rooms in the Vatican, which Alexander had just built. These rooms, called after their founder the Appartamenti Borgia, now form part of the Vatican library, and five of them still retain the fine series of frescoes with which they were so skilfully decorated by Pinturicchio. The upper part of the walls and vaults, not only covered with painting, but further enriched with delicate stucco work in relief, are a masterpiece of decorative design applied according to the truest principles of mural ornament—a much better model for imitation in that respect than the more celebrated Stanze of Raphael immediately over the Borgia rooms. The main subjects are: (1) the Annunciation, the Nativity, the Magi, and the Resurrection; (2) Scenes from the lives of St. Catherine, St. Antony and other saints; (3) allegorical figures of music, arithmetic and the like; (4) four figures in half length, with rich arabesques; (5) figures of the planets, the occupations of the various months, and other subjects. The sixth room was repainted by Perino del Vaga.1

Though not without interruption, Pinturicchio, assisted by his pupils, worked on these rooms from 1492 to 1498, when they were completed. His other chief frescoes in Rome are still existing in a very genuine state, are those in the Cappella Bufalini at the south-west of S. Maria in Ara Coeli, probably executed from 1497 to 1500. These are well-designed compositions, noble in conception, and finished with much care and refinement. On the altar wall is a grand painting of St Bernardino of Siena between two other saints, crowned by angels; in the upper part is a figure of Christ in a vesica-glory, surrounded by angel musicians; on the left wall is a large fresco of the miracles done by the corpse of St Bernardino, very rich in colour, and full of very carefully painted heads, some being portraits of members of the Bufalini family, for whom these frescoes were executed. One group of three females, the central figure with a child at her breast, is of especial beauty, recalling the grace of Raphael's second manner. The composition of the main group round the saint's corpse appears to have been suggested by Giotto's painting of St. Francis on his bier in S. Croce at Florence. On the vault are four noble figures of the Evangelists, usually attributed to Luca Signorelli, but certainly, like the rest of the frescoes in this chapel, worked in hand of Pinturicchio. On the vault of the sacristy of S. Cecilia in Trastevere, Pinturicchio painted the Almighty surrounded by the Evangelists. During a visit to Orvieto in 1496 Pinturicchio painted two more figures of the Latin Doctors in the choir of the duomo—now, like the rest of his work at Orvieto, almost destroyed. For these he received fifty gold ducats.

Among his panel pictures the following are the most important. An altarpiece for S Maria de' Fossi at Perugia, painted in 1496-1498, now moved to the picture gallery, is a Madonna enthroned among Saints, graceful and sweet in expression, and very minutely painted; the wings of the retable have standing figures of St Augustine and St Jerome; and the predella has paintings in miniature of the Annunciation and the Evangelists. Another fine altarpiece, similar in delicacy of detail, and probably painted about the same time, is that in the cathedral of San Severino—the Madonna enthroned looks down towards the kneeling donor. The angels at the sides in beauty of face and expression recall the manner of Lorenzo di Credi or Da Vinci. The Vatican picture gallery has the largest of Pinturicchio's panels—the Coronation of the Virgin, with the apostles and other saints below. Several works executed by pupils occur among the kneeling saints. The Virgin, who kneels at Christ's feet to receive her crown, is a figure of great tenderness and beauty, and the lower group is composed with great skill and grace in arrangement. Other important panel paintings by Pinturicchio exist

1 See Guattani, Quadri nell' appar. Borgia (Rome, 1820).
in the cathedral of Spello, in the Siena gallery, at Florence, at Perugia, and in other collections.

In 1501 Pinturicchio painted several fine frescoes in S. Maria Maggiore in Rome, which are decorative and full of elaborate architectural accessories. One of them, the Annunciation, is signed "Bernardino Pinturichio Pervisivs." The most striking of all Pinturicchio's frescoes, both for brilliance of colour and their wonderful state of preservation, are those in the cathedral library at Siena, a large room built in 1495 by Cardinal Francesco Piccolomini, afterwards Pius III. In 1502 the cardinal contracted with Pinturicchio to decorate the whole room with arabesques on the vault, and on the walls ten scenes from the life of Aeneas Sylvius Piccolomini, Pius II., the uncle of Cardinal Francesco.

The contract specially provided that the cartoons, their transference on to the walls, and all the heads, were to be by Pinturicchio's own hand, thus contradicting Vasari's assertion that the cartoons were the work of Raphael. The document provides for the price of these frescoes, namely one thousand gold ducats, to be paid in various instalments. The work was begun early in 1503, but was interrupted for a while by the death of Pius III. His will, however, provided for the completion of the execution by the executors, and the whole series were finished in 1507. The subjects are (1) the journey of the young Sylvius Piccolomini to the Council of Basel, in the suite of Cardinal Capranica; (2) his reception by Janus Gallicanus; (3) his deposition from the Council of Basel; (4) his being crowned with the poet's laurel by Frederick III.; (5) his reception by Pope Eugenius IV. as ambassador from Frederick III.; (6) outside the wall of Siena he presents to Frederick III. his bride Leonora, infanta of Portugal; (6) he receives the cardinal's hat from Pope Calixtus III.; (7) he is borne in procession after his election as Pope Pius II.; (8) he presides at a council at Mantua; (9) he canonizes St Catherine of Siena; (10) he arrives in Ancona to promote the crusade against the Turks. In addition to these the cartoons for the library, over the door, the coronation of Pius III. In the lower part of the scene of St Catherine's canonization he has introduced his own portrait, and standing by him is a youth who bears some resemblance to Raphael.

In 1508 Pinturicchio painted another panel of the Madonna enthroned among saints for the church of the Minori Conventual at Spello. In 1515 he went to the Gallery of France, and on his return to Siena he painted a whole series of frescoes on the walls of the Palazzo Petrucci, now all destroyed except one scene of the return of Ulysses to Penelope (or possibly Collatinus and Lucretia), which is now in the National Gallery of London, transferred to canvas. One of his last works, painted in 1513, the year of his death, is a very beautiful and highly finished panel with Christ bearing His Cross, now in the Palazzo Borromeo in Milan. Pinturicchio married Grania di Niccolò, and had by her two sons and four daughters; there is probably no truth in the story of his being starved by his wife during his last illness.

Pinturicchio's worth as a painter has been for too long its most undervalued, partly owing to the almost complete silence that has been kept about him, which exaggerates Vasari's biography of him. Even Crowe and Cavalasarre hardly did him justice. A fairer estimate of his position in the history of art is given by Vermiglioli, Memorie di Pinturicchio (Perugia, 1837); and in the valuable notes and appendix of Milanesi, Pinturicchio, iii., 493-531 (Florence, 1878). See also Schmarsow, Raphael und Pinturicchio in Siena (Stuttgart, 1880), and Pinturicchio in Rom (Stuttgart, 1882), both well illustrated by photo-lithography.

PINWELL, GEORGE JOHN (1842-1875), British water-colour painter, was born at Wycombe, and educated at Heatherley's Academy. He is one of the most interesting personalities in the little group of water-colour painters which included Frederick Walker, and the younger Pre-Raphaelists, because his work was derived from the practice of drawing upon wood for book illustration. He was one of the most delightful book illustrators of his day, poetic in imagination, with considerable inventive power and an admirable sense of colour. As he died young his works are few, but their promise was so great that had he lived he would probably have attained a very high position. His early life was one of considerable privation. In 1862 he entered at Heatherley's studio and there obtained his art education. His earliest drawings appeared in Lilliput Leève. He did a little work for Fun and exercised several designs for the silversmiths, Elkingtons. In 1863 his first drawing appeared in Once a Week, and from that time his work was in constant demand. There are many of his compositions in Good Words, The Sunday Magazine, The Quater and London Society, but his most important productions were the illustrations of Goldsmith, of Jean Ingelow's poems, Robert Buchanan's Ballads of the Afections, and the Arabian Nights.

Of Pinwell's pictures in colour, which are distinguished by a remarkable, jewel-like quality and marked by his strong love of pure, bright colour and opalescent effect, the chief are the two scenes from the Pied Piper of Hamelin, Gilbert à Beckett's Truth, Out of Tune or The Old Cross, A Seat in St James's Park, and The Elixir of Life.

In 1874 Pinwell fell seriously ill and went to Africa for the winter. He painted several remarkable pictures at Tangier, but his strength gradually broke down and he returned to die in his wife's arms on the 8th of September 1875. Pinwell was an exhibitor at the Dudley gallery, and in 1860 was elected associate of the Royal Water-Colour Society and full member in 1870; to this gallery he contributed fifty-nine works. A posthumous exhibition of his works was held in 1876 in Bond Street.

PINZON, a family of wealthy Spanish navigators of Palos in Andalusia, three members of which—Martin Alonzo, Francisco and Vicente Yáñez, brothers—were associated with Columbus in the discovery of America.

MARTIN ALONZO PINZON, born about the middle of the 15th century, gave material assistance to Columbus in carrying out his project. "If Colon was the head, Pinzon was the right arm" (Asensio). In the expedition of 1492 he commanded the "Pinta," on which his brother Francisco was pilot; another brother, Vicente Yáñez, commanded the "Nina." On the 6th of October Martin Alonzo suggested to Columbus (when already in the longitude of the Bermudas) to change the course of the expedition from due west to south-west; on the 7th of October this suggestion—strengthened by the observation of a flight of birds to the south-west—was adopted, bringing the fleet, four days later, to the landfall at Guanahani (San Salvador, Watling Island) in the Bahamas (Oct. 12, 1492). On the 21st of November 1492, near the east end of the north coast of Cuba, Martin Alonzo left Columbus, making eastward in search of the gold mines of which they had heard the natives speak. On the 4th of January 1493 he arrived on the coast of the Bahamas.

But on the return journey he again left his leader, and when Columbus arrived at Palos on the 15th of March 1493 he learned that Alonzo had already landed at Bayona in Galicia. If his object was to forestall Columbus and pose as discoverer of the New World, he was foiled; audience was refused him by Ferdinand and Isabella; and soon after he died, perhaps of chagrin.

VICENTE YÁÑEZ PINZON, who commanded the "Nina" in 1492-1493, also gave Columbus material help, and remained loyal to his leader throughout. In after years he made important discoveries on his own account. Late in December 1499 he sailed with four caravels across the Atlantic to the south-west, and on the 7th of February 1500 he struck the South American continent at Cape S. Agostinho, near its most easterly projection (called by him Cape Santa Maria de la Consolacion) almost three months before the Portuguese navigator Cabral reached Brazil, the discovery of which is generally attributed to him. Proceeding southwards a short north, he then turned northward, crossed the line between the north-west, discovered the Amazon estuary, and went at least as far as the mouth of the Plata River. After touching at Haiti, and losing two of his vessels among the Bahamas, Vicente returned to Palos in the end of September 1500. Although concessions were made to him, and he was created governor of the newly discovered lands by Ferdinand and Isabella, he does not seem to have ever taken possession. In 1507 we find Vicente sailing with Juan Diaz de Solis along the east coast of Central America. In 1509, again with De Solis, he coasted the Atlantic side of South America as far as the La Plata estuary, hoping to find an opening westwards leading to the Spice Islands. According to Herrera, he even reached 46°S,
PIO DI SAVIOA, an ancient noble Italian family, first mentioned by good authorities in the 14th century. From the house of Este (g.v.) they received the lordship of Carpi, and later they acquired the fiefs of Meldola, Sassuolo, &c. Many members of the family were distinguished as condottieri, diplomats and ecclesiastics. Alberto Pio obtained from the house of Savoy in 1450 the privilege of adding "di Savoia" to his name as a reward for his military services. Another Alberto Pio (1475-1518), who was French ambassador in Rome, won fame as a man of learning, and Cardinal Rodolfo Pio (1516-1564) was a trusted adviser to Pius III, and helped to establish the Inquisition at Milan. Asciano Pio (d. 1649) was a dramatic poet of some merit. Spain conferred the title of prince on the family, and one branch of it is to this day established in Spain.

PIOZZI, HESTER LYNCH (1741-1821), English writer, well known as the friend (Mrs Thrale) of Samuel Johnson (g.v.), was born on the 16th of January 1741, his father being John Salusbury of Bobble, Carnarvonshire. Her maternal uncle, Sir Robert Salusbury Cotton, contemplated providing for his niece, but he died without having carried out his intention. She and her mother lived in London, and amongst her childish recollections were meetings with James Quin and David Garrick. She received a solid education, for she was acquainted with Latin as well as with French, Italian and Spanish. In 1763 she was married to Henry Thrale, a rich Southwark brewer, whose house was at Streatham on the south-east corner of Tooting Bec Common. There was very little sympathy between the lively girl and Thrale, who was thirteen years her senior, but gradually she drew round her a distinguished circle of friends. She was introduced to Samuel Johnson in 1765 by Arthur Murphy, who was an old friend of her husband's. In 1766 Johnson paid a long visit to Streatham, and from that time was more or less domiciled with the Thrales. In time it became his custom to spend the middle of the week at Streatham, devoting the remaining days to his own heterogeneous "family." He was genuinely attached to his hostess, and thoroughly appreciated the luxury in which the Thrales lived. They were able to soften some of his eccentricities, and they certainly made him happy. He travelled with them in Wales in 1774, and in France in 1775. Dr Burney gave lessons to one of the Miss Thrales, and in 1778 he brought his daughter Fanny to Streatham. She became a warm friend of Mrs Thrale, and has left an account of the Streatham household in her diary. This friendship was by no means always unclouded. Fanny Burney was very sensitive, and sometimes thought that Mrs Thrale gave herself airs of patronage. Meanwhile, in 1772, Thrale's business was seriously injured, and he was threatened with bankruptcy. The situation was saved by his wife's efforts, and in the next year Thrale travelled, leaving her in charge of his affairs. He was twice returned for the borough of Southwark, chiefly through her influence. In 1781 Mr Thrale died, and Dr Johnson helped the widow with her business arrangements, advising her to keep on the brewery, until she cured his honest heart of its incipient passion for trade, by letting him into some, and only some, of its mysteries." The brewery was finally sold for £135,000. Mrs Thrale had met Gabriele Piozzi, an Italian musician, in 1780. Johnson was now in failing health, and soon began to feel himself slighted. His suspicions were definitely aroused when she laid aside her mourning for Thrale in 1782, and the Streatham house was sold. In 1783 her engagement to Piozzi was announced. The objections of her daughters and her friends induced her to break it off for a time, but it was soon resumed, and in 1784 they were married. Johnson told Miss Burney that he drove the memory of Mrs Thrale from his mind, burning every letter of hers on which he could lay his hand. The Piozzis presently left England to travel in Italy. At Florence they fell in with Robert Merry and the other "Della Cruscan" writers ridiculed by William Gifford in his Macièd and Baylod, and they contributed some verses to their Florence Miscellany in 1785. The Piozzis presently left England to travel in Italy. At Florence they fell in with Robert Merry and the other "Della Cruscan" writers ridiculed by William Gifford in his Macièd and Baylod, and they contributed some verses to their Florence Miscellany in 1785. In 1786 she published Anecdotes of the late Samuel Johnson, during the last twenty years of his life, which was severely criticized by Boswell. She was ridiculed by "Peter Pindar" in Bossey and

PIPE, a term used of a musical wind-instrument of tubular form, and hence of any cylindrical hollow tube. The original application of the term is to the musical instrument (see Pipe and Tabor below), and the source is to be found in Lat. pipere, to chirp, of a bird. The general meaning of "pipe," in the sense of a tube for such purposes as carrying water, gas, sewage, &c., is treated under Tube. Among specific uses of the word are those for the hollow stem of clay, wood or other material with a bowl at one end in which tobacco is smoked (see below); for the metal or wooden sound tubes in an organ (q.v.); and for various forms of cylindrical veins, hollows, channels, &c., in mining and geology. The Great Roll of the Exchequer was known as the "Pipe Roll"; this contained the various "pipes" or enrolled accounts of the sheriffs, &c., which were so called either from being in a cylindrical case or as resembling a pipe in shape when rolled (see Records).

Tobacco Pipe.—The smoking of tobacco in pipes is a custom which prevailed in America for a period of unknown duration previous to the discovery of that continent by Columbus. The most ancient pipes of which remains exist have been found in mounds or tumuli, called pipe mounds, principally, in Ohio, Indiana, Illinois and Iowa. These pipe mounds, which are carved in porphyry and other hard stones, are very uniform in type. The pipes, cut out of a single piece of stone, consists of a slightly convex platform or base, generally from 3 to 4 in. in length, and about an inch broad, with the bowl on the centre. A fine hole is pierced from one end of the platform to the bottom of the bowl, the opposite end being obviously for holding in the hand while the pipe is being smoked. In the commonest forms the bowl is a simple cylinder or urn (fig. 1), but in many cases remarkable artistic skill has been displayed in carving the bowls into miniature figures of birds, mammals, reptiles and human heads, often grotesque and fantastic, but always vigorously expressed (fig. 2). These mound or platform pipes with carved human and animal forms are objects of the highest ethnographic interest and importance, being among the most characteristic remains of the ancient inhabitants of the Mississippi valley. The wide area over which they, as well as remains of baked clay pipes, are found throughout the American continent testifies to the universal prevalence of smoking in the pre-Columbian era. Many of the ancient clay pipes found in Mexico, &c., are elaborately moulded and ornamented, while others show considerable similarity to the early clay pipes of Europe. Among the North-American Indian tribes the tobacco pipe occupies a position of peculiar symbolic significance in connexion with the superstitious rites and usages of the race. The calumet, peace pipe or medicine pipe, is an object of the most profound veneration, entrusted to the care of a highly honoured official, and produced and smoked with much ceremony only on occasions of great importance and solemnity. It is remarkable that, whilst the most ancient American pipes had no separate stem, it is the stem only of the medicine pipe which... is the object of veneration among the Indians, the bowl used being a matter of indifference. The favourite material for Indian pipe bowls is the famous red pipe stone (catlinite), a fine-grained easily-worked stone of a rich red colour of the Cateau des Prairies, west of the Big Stone Lake in S. Dakota. The quarries were formerly neutral ground among the warring Indian tribes, many sacred traditions being associated with the locality and its product.

It is disputed whether pipes for smoking were at all known in Europe previous to the discovery of America. That tobacco-smoking was unknown is certain; but pipes of iron, bronze and clay have been so frequently found associated with Roman remains and other antiquities as to lead many authorities to maintain that such pipes must have been anciently used for burning incense or for smoking aromatic herbs or hemp. Throughout Great Britain and Ireland small clay pipes are frequently dug up, in some instances associated with Roman relics. These are known amongst the people as elfin, fairy or Celtic pipes, and in some districts supernatural agencies have been called in to account for their existence. The elfin pipes have commonly flat broad heels in place of the sharp spur now found on clay pipes, and on that flat space the mark or initials of the maker is occasionally found. There is no reason to believe that these pipes are older than the 17th century. The introduction of the tobacco pipe into Europe is generally ascribed to Ralph Lane, first governor of Virginia, who in 1586 brought an Indian pipe to Sir Walter Raleigh, and taught that courtier how to use the implement. The pipe-makers of London became an incorporated body in 1619, and from England the other nations of Europe learned the art of making clay pipes.

The habit of smoking with pipes spread with incredible rapidity, and among the various peoples the pipe assumed special characteristics, and its modifications became the medium of conveying social, political and personal allusions, in many cases with no little artistic skill and humour. The pipe also became the object of much inventive ingenuity, and it varied as greatly in material as in form—wood, horn, bone, ivory, stone, precious and other metals, amber, glass, porcelain and, above all, clay being the materials employed in various forms. By degrees pipes of special form and material came to be associated with particular people, e.g. the elongated painted porcelain bowls and pendulous stem of the German peasantry, the red clay bowl and long cherry wood stem of the Turk, and the very small metallic bowl and cane stem of the Japanese, &c. Among other kinds of pipe which have been popular at various times are the "corn-cob," where the bowl is made of the cob of maize or Indian corn, and the "calabash" with the bowl of a small gourd. The "churchwarden" is a clay pipe with a slender stem, some 16 or 20 in. long. The most luxurious and elaborate form of pipe is the Persian kalinyan, hookah or water tobacco pipe. This consists of three pieces, the head or bowl, the water bottle or base, and the snake or long flexible tube ending in the mouthpiece. The tobacco, which must be previously prepared by steeping in water, is placed in the head and lighted with live charcoal, a wooden stem passes from its bottom down into the water which fills the base, and the tube is fitted to a stem which ends in the bottle above the water. Thus the smoke is cooled and washed before it reaches the smoker by passing through the water in...
the bottle, and by being drawn through the coil of tube frequently some yards in length. The bottles are in many cases made of carnelian and otherwise ornamented coconut shells, whence the apparatus is called närgila, from närgil, a coconut. Silver, gold, damascened steel and precious stones are freely used in the making and decoration of these pipes for wealthy smokers.

**Pipe Manufacture.**—The regular pipe-making industries divide into many branches, of which the more important are the clay pipe, meerschaum (real and artificial), and wooden bowls. Clay pipes are made in prodigious numbers by hand labour with an iron mould and a steel wire for forming the tube of the stem. Pipe-moulding is a very simple operation in pottery, and the work is performed with astonishing celerity. A number of machines have been devised for automatic pipe-moulding; but the manual operations are so rapid and inexpensive that there is little margin for saving by the substitution of machinery. The pipes are very slightly fired so as to keep them soft and porous; and so cheaply made are they that the commoner kinds can be retailed at a profit for a farthing each. The principal early centres of the clay-pipe industry were at Broseley in Staffordshire, where the trade has been established since the early part of the 17th century, and at Amesbury in Wiltshire. The manufacture is still carried on at Broseley. Meerschaum pipes (see MEERSCHAUM) are the luxury of the European smoker. The favourite wooden pipe generally known as a briar-root or **pipa-root** pipe is really made from the roots of the tree Eurya (Fr. Eurydice), principally obtained on the hills of the Maremma and taken thence to Leghorn. There the roots are shaped into blocks each suitable for a pipe, the cutting of the wood so as to avoid waste requiring considerable skill. These blocks are simmered in a vat for twelve hours, which gives them the much-appreciated yellowish-brown hue of a good **pipa-root**. So prepared the blocks are exported for boring and finishing. Many devices have been invented for the purpose of preventing the nicotine liquid from reaching the smoker’s mouth or collecting in and fouling the pipe.

**PIPE AND TABOR** (Fr. galoubet; Ger. Schwiegel oder Stammtenischenpfeiff), a popular medieval combination of a small pipe or flageolet, and a small drum. The pipe consists of a cylindrical tube of narrow bore, pierced with three holes, two in front and one at the back, all very near the end of the pipe; and of a mouthpiece of the kind known as whistle, flipple or beak common to the flûte à lec or recorder family. The compass of this instrument, with no more than three holes, exceeds two octaves in the hands of a good player, and is chromatic throughout. The fundamental notes of the open pipe and of the three holes cannot be produced; the scale consists, therefore, entirely of harmonics. The 2nd, 3rd and 4th of the series being easily obtained, and, by half stopping the holes, also the semitones which are required to complete the chromatic scale. The tabor being fastened to the performer’s left elbow, the hands remained free, the right beating the little drum with a stick to mark the rhythm, while the left held and fingered the pipe with thumb and first two fingers.

Mersenne mentions a wonderful virtuoso, John Price, who could rise to the twenty-second on the galoubet. Praetorius mentions and figures three sizes of the Stammtenischenpfeiff, the treble of 20 in. long, the tenor 26 in. and the bass 30, the last being played by means of a crook about 23 in. long. A specimen of the bass in the museum of the Brussels Conservatoire has for its lowest note Middle C. The pipes and tabor are said to be of Provençal origin; it is certain that they were most popular in France, England and the Netherlands, and they figure largely among the musical and social scenes in the illuminated MSS. of those countries. (K.S.)

**PIPE-FISHES** (**Syngnathidae**), small fishes, which with the Sea-horses form a distinct family, **Syngnathidae**, of Lophobranchiata narrow and small mouth which opens upwards and is toothless. The body and tail are long and thin, snake-like, encased in hard integuments which are divided into regularly arranged segments. This dermal skeleton shows several longitudinal ridges, so that a vertical section through the body represents an angular figure, not round or oval as in the majority of other fishes. A dorsal fin is always present, and is the principal (in some species, the only) organ of locomotion. The ventral fins are as constantly absent, and the other fins may or may not be developed. The gill-openings are extremely small and placed near the upper posterior angle of the gill-cover. Most of the pipe-fishes are marine, only a few being fluvial. Pipe-fishes are abundant on such coasts of the tropical and temperate zones as offer by their vegetation shelter to these defenceless creatures. They are very bad swimmers, slowly moving through the water by means of the rapid undulatory movement of the dorsal fin. Their tail, even when provided with a caudal fin, is of no use in swimming, and not prehensile as in sea-horses. Specimens, therefore, are not rarely found at a great distance from land, having been resistlessly carried by currents into the open ocean; one species, **Syngnathus pelagicus**, has an extraordinarily wide range over the tropical seas, and is one of the common fishes inhabiting the vegetation of the Sargasso Sea. The colour of these fishes often changes with the sea-weeds among which they may be found, passing from brown to green or even brick-red. In pipe-fishes the male is provided with a pouch—in some species on the abdomen, in others on the lower side of the tail—in which the ova are lodged during their development. This marsupial pouch is formed by a fold of the skin developed from each side of the trunk or tail, the free margins of the fold being firmly united in the median line throughout the period during which the eggs are being hatched. When the young are hatched the folds separate, leaving a wide slit, by which the young gradually escape when quite able to take care of themselves. Nearly a hundred different species of pipe-fishes are known, of which **Siphonostoma typhle**, **Syngnathus acus** (the Great Pipe-fish up to 18 in. in length), **Nerophis aequoreus** (Ocean Pipe-fish), **Nerophis opisthon** (Straightnosed Pipe-fish), and **Nerophis lumbriciformis** (Little Pipe-fish) are British species. The last three are destitute of a caudal fin.

**PIPER, CARL, COUNT** (1617-1716), Swedish statesman, was born at Stockholm on the 29th of July 1617. He entered the foreign office after completing his academic course at Upsala, accompanied Benedict Oxenstierna on his embassy to Russia in 1673, and attracted the attention of Charles XI. during the Scanian War by his extraordinary energy and ability. In 1679 he was appointed secretary to the board of trade and ennobled. In 1680 he was made one of the secretaries of state, and Charles XI. recommended him on his deathbed to his son and successor, Charles XII. Piper became the most confidential of the new sovereign’s ministers. In 1697 he was made a senator and set over domestic affairs while still retaining his state-secretaryship. In 1698 he was created a count, in 1702 appointed chancellor of Upsala University, and during the first half of the Great Northern War, as the chief of Charles’s parlementing chancellor, he was practically prime minister. It was his misfortune, however, to be obliged to support a system which was not his
own. He belonged to the school of Benedict Oxenstjerna and was therefore an avowed advocate of a pacific policy. He protested in vain against nearly all the military ventures of Charles XII., e.g. the War of Deposition against Augustus of Saxony and Poland, the invasion of Saxony, the raid into the Ukraine. Again and again he insisted that the pacific overtures of Peter the Great should at least be fairly considered, but his master was always immovable. Piper's career came to an end at Poltava (1709), where he was among the prisoners. The last years of his life were spent in exile in Russia. He died at Schlüsselburg on the 20th of May 1716.

Piperazin—Pippin

PIPERAZIN, a substance formed by the action of sodium glycol on ethylene-diamine hydrochloride, consisting of small alkaline deliquescent crystals with a saline taste and soluble in water. It was originally introduced into medicine as a solvent for uric acid. When taken into the body the drug is partly oxidized and partly eliminated unchanged. Outside the body piperazin has a remarkable power of dissolving uric acid and producing a soluble urate, but in clinical experience it has not proved equally successful. Lycetol, lysidine and sidonal are bodies having similar action.

Piperine, C_{17}H_{19}NO_{3}, an alkaloid found in the fruits of Piper nigrum and P. longum. It forms white prisms, which melt at 128°—210°. It is almost insoluble in water, but readily soluble in alcohol and ether. It is a very weak base, salts being only formed with mineral acids, and these are dissociated by water. Alcoholic potash decomposes it into piperidine, C_{8}H_{8}N, and piperic acid, C_{8}H_{7}O_{3}. The constitution of piperic acid was elucidated by R. Fittig and his pupils (Ann., vols. 152, 159, 168, 216, 227) and shown to be (1). Piperine consequently is (2).

\[
\text{(1)} \quad \text{CH}_3-\text{CH}_2-\text{CH}_2-\text{CH}\cdot\text{CO}\cdot\text{NH}_2 \\
\text{(2)} \quad \text{CH}_2-\text{CH}_2-\text{CH}_2-\text{CH}_2-\text{CO}\cdot\text{NH}_2(\text{CH}_2)_3
\]

Oxidation with potassium permanganate converts piperic acid into piperonal, C_{1}H_{6}O_{3}, and piperonylic acid, C_{3}H_{4}O_{3}. The latter, when heated with hydrochloric acid to 170°, or water to 200°, separates carbon with the formation of protocatechuic acid, C_{8}H_{4}(OH)_2COOH. Conversely, by heating protocatechuic acid with potash and methylene iodide, piperonylic acid was regained. These results show that piperonylic acid is derived from the methylene ether of protocatechuic acid. Piperonal (q.v.) is the corresponding aldehyde. Piperic acid differs from piperonylic acid by the group C_4H_4, and it was apparent that these carbon atoms must be attached to the carbon atom which appears in the carbonyl group of piperonylic acid, for they were directly attached to the benzene ring polyarboxylic acids would result in oxidation. The above formula for piperonal was confirmed by its synthesis by A. Ladenburg and M. Scholtz (Ber., 1894, 27, p. 2938) from piperonylic acrolein (the condensation product of piperonal and acetaldehyde) and acetic acid. The synthesis of piperine follows from the interaction of piperonyl chloride (formed from piperic acid and phosphen pentachloride) and piperidine (L. Rüegger, Ber., 1882, 15, p. 1390).

Piperno (anc. Prirnum), a town of the province of Rome, Italy, marked S.E. of Rome by rail. Pop. (1901), 6736. The medieval town was founded in the 10th century (?) on a hill 490 ft. above sea-level, by refugees from the Roman town of Prerunum, lower down (118 ft. above sea-level) on the highway 1½ m. to the north, at the mouth of a low pass leading through the Volscian mountains to the valley of the Sacco. Here are remains of an arch crossing the road and other ruins (mostly buried) of the Roman period, but the remains above ground are largely medieval. It is improbable, however, that the ancient Volscian town should have occupied so easily accessible a site; it is not unlikely that it stood on the site occupied by the medieval and modern town, but there is no proof of this. Prerunum was a Volscian town, and took up arms against Rome after the foundation of a Latin colony at Setia in 382 B.C. It was finally captured in 329 B.C., and eleven years later the tribus Ouentina was founded, taking its name from the river Ouen (mod. Ufente) in the territory of Prerinum. Little is known of it subsequently. The medieval town has a picturesquely piazzas with a Gothic cathedral (1282), which preserves a fine porch, though the interior was much modernized in 1782; a Gothic palazzo pubblico; and other Gothic churches exist in the town. Polygonal terrace walls of the Roman or pre-Roman period exist at various places in the vicinity (G. B. Giovenale and L. Marianì in Notiziogli degli Scavi, 1899, 88).

Piperonal (hetiolate, protocatechuic aldehyde methylene ether), C_{1}H_{6}O_{3}, an aromatic aldehyde. It is prepared by oxidizing piperic acid with potassium permanganate (R. Fittig, Ann., 1869, 152, p. 35); by condensing methylene iodide with protocatechuic aldehyde (R. Wegscheider, Monats., 1893, 14, p. 388); or by oxidizing isosafrol with chromic acid. It forms long colourless crystals which melt at 37° C. and boil at 263° C. It has an agreeable smell, resembling that of hetiolate, and is much used in perfumery. It is only slightly soluble in cold water, but is readily soluble in alcohol and in ether. When heated with dilute hydrochloric acid to 200° C. it yields protocatechuic aldehyde, C_{1}H_{6}O_{3}, and carbon. It readily combines with sodium bisulphite and with various bases (ammonia, aniline, methylamine).

Pipit (cognate with the Lat. Pippio; see PIPERON), the name applied by ornithologists to a group of birds having a great resemblance both in habits and appearance to the larks (q.v.). They differ however from larks in several important characters, and, having been first separated to form the genus Anthus, which has since been much broken up, are now generally associated with the wagtails (q.v.) in the passerine family Motacillidae. Pipits, of which over fifty species have been described, occur in almost all parts of the world, but in North America are represented by only two species—Neocorys squagri, the prairie-lark of the north-western plains, and Anthus ludovicianus, the American titlark, which last is very nearly allied to the so-called water-pipit of Europe, A. sipioletta. To most English readers the best known species of pipit is the titlark or meadow-pipit, A. pratensis, a bird too common to need description, and abundant on pastures, moors, and uncultivated districts generally; but in some localities the tree-pipit, A. trivialis, or A. boreus of some authors, takes its place, and where it does so it usually gains attention by its loud song, which is not unlike that of a canary, but delivered at a pace and with a warbling quality which is not heard by the rest of the world in its brighter coloration, which has a curious resemblance to the American genus Stumella (see Icterus), though the bird is certainly not allied thereto.

Pippin, or Pipin, the name of three members of the Carolingian family.

Pippin I. (d. 640), incorrectly called Pippin of Landen, was mayor of the palace to the youthful Dagobert I., whom Chlotar II. had placed over the kingdom of Austrasia. He was disgraced when Dagobert became sole king in 629, and had to seek refuge in Aquitaine. Returning at Dagobert's death (639), he governed Austrasia in Sigebert's name, but died in the following year.

Pippin II. (d. 714), incorrectly called Pippin of Herstal, was son of Adalgisius (son of Arnulf, bishop of Metz) by a daughter of Pipin L. called in later documents Begga. Towards 678 he placed himself at the head of the great nobles in Austrasia to combat Ebroin, the mayor of the palace, and Neustria. After some reverses he gained a great victory after Ebroin's death at the battle of Tertry, not far from St Quentin. This victory made Pippin almost entire master of Gaul. He appointed one of his sons mayor of the palace of Neustria, reserving for another of his sons the mayoralty of Austrasia. He made war...
on the Frisians and defeated their duke Radbod; and part of this people became converts to Christianity. He also defeated Willari, the duke of the Alamanni, and subdued his country. The Bavarians, too, recognized the Frankish suzerainty. The plan Pippin had formed for reforming the church and convoking councils were interrupted by his death, which took place on the 16th of December 714.

Pippin III. (d. 768), the Short, was son of Charles Martel. Before his death in 741 Charles Martel had divided the Frankish kingdom between his two sons, Carloman and Pippin, giving Carloman the eastern part and Pippin the western. Since 737 there had been no king in the Frankish realm; in the diplomas the two brothers bear the title of majors palatii, while the chroniclers call them simply principes. In 743, however, the mayors decided to appoint a king in the person of Childeric III., who was apparently connected with the Merovingian family. But Childeric was a mere figure-head, and had no power.

The two brothers presided over the tribunals, convoked the councils at which the Frankish Church was reformed, assembled the host and made war, jointly defeating and subduing Duke Hunald of Aquitaine. In 747 Carloman unexpectedly abdicated, became a monk, and retired to a monastery near Rome, subsequently founding Mt. Soratte the monastery of St. Silverste. From the time of the abdication Pippin was sole master; and in 751, after consulting Pope Zacharias, he took the title of king and removed the feeble Childeric to a monastery. He then got himself crowned by St. Boniface, a ceremony which was new to France and which gave the sovereign immense prestige; henceforth the king of the Franks called himself Gratia Dei rex Francorum. Pippin's reign is marked by many important events. He received in France a personal visit from Pope Stephen II., who conferred on him the title of Patrician of the Romans and reconfirmed him. In return for these honours Pippin, at the appeal of the Papacy, made two expeditions into Italy, in 754 and 756; and he became the veritable creator of the papal state by conferring on the pope the exarchate of Ravenna, which he had wrested from Aistulf, the king of the Lombards. Pippin took Septimania from the Arabs, and after a stubborn war of nearly eight years' duration (762-68) succeeded in taking Aquitaine from its duke, Waifer. He also intervened in Germany, where he forced the duke of Bavaria, Tassilo, to become his vassal. In 763, however, Tassilo abandoned Pippin during an expedition against Aquitaine. Pippin made several expeditions against the Saxons, but failed to subdue them. He entered into relations with the Eastern Empire, exchanging ambassadors with the emperor Constantine Copronymus. During Pippin's reign Frankish inscriptions underwent some modification. The Frankish assemblies, previously held in the month of March (champs de mars), but under Pippin deferred to May (champs de mai), came to be more numerous, and served the king of the Franks as a means of receiving the gifts of his subjects and of propagating his capitularies. At the head of the administration was placed the archchapelain, and an ecclesiastical chancellor was substituted for the ancient referendarius. Ecclesiastical reform was continued under Pippin, Bishop Chrodegan of Metz uniting the clergy of Metz in a common life and creating canons (see Canon). Pippin died on the 24th of September 768 at St. Denis, leaving two sons, Charles (Charlemagne) and Carloman.

Oelsner, Jahrbücher des fränkischen Reiches unter König Pippin (Leipzig, 1871); F. Böhmer and E. Mühlbacher, Regesta des Kaiserreiches unter den Karolinger (2nd ed., 1839); and E. Mühlbacher, Deutsche Geschichte unter den Karolinger (Stuttgart, 1896).

PIPĀWA, a village on the Birdpur estate in the Basti district, United Provinces, India. It lies on the Uska-Nepal road at mile 19-75; and about half a mile south of the boundary pillar numbered 44 on the frontier line between British and Nepalese territory. The village is celebrated as the site of the following discovery:—

In 1896 interest having been aroused by the discovery, only twelve miles away, of the Buddha's birthplace (see Lumbini), Mr. Pippé, then resident manager of the Birdpur estate, opened a ruined tope or burial mound situate at Pipawa, but nothing of importance was found. In January 1897 he carried the work of excavation farther. A well, 10 ft. sq., was dug down the centre of the mound. After digging through 18 ft. of solid brickwork set in clay a massive stone cofar was found lying due magnetic north and south. Its dimensions were, 4 ft. 4 in. by 2 ft. 8½ in. and 2 ft. 21 in. high. The stone lid of the cofar was split into four pieces; but the cofar remained perfectly closed, so accurately was the lid fitted down flanges on the sides of the box. The pieces were thus firmly held in their place, and the contents of the cofar were found intact. These consisted of five vessels, two vases, a bowl and a casket being made of steatite, and the fifth, also a bowl, of crystal. All these vessels are beautifully worked, the crystal bowl especially, with its fish-shaped cover handle, being as a work of art of high merit. The cofar is of fine hard sandstone of superior quality, and has been hollowed out, at the cost of vast labour and expense, from a solid block of rock. Pippé calculates its weight, lid included, at 1537 lb. It is only the great solidity of this cofar which has preserved the contents. A cover of one of the vases was found dislodged and lying on the bottom of the stone cofar. As this cover fits very well it must have required a quite violent shock to remove it. This was almost certainly the shock of an earthquake, and the same shock probably caused the split in the stone lid of the cofar itself.

The vessels contained a dark dust, apparently disintegrated ashes, small pieces of bone, and a number of small pieces of jewelry in gold, silver, white and red cornelian, amethyst, topaz, garnet, emerald, and crystal. Most of these are perforated for mounting on threads or wires, and had been, no doubt, originally connected together to form one or more of the elaborate girdles, necklaces and breast ornaments then worn by the women. On the bottom of the stone box there was similar dust, pieces of bone and jewelry, and also remains of what had been vessels of wood. The knob forming the handle of one of these wooden receptacles was still distinguishable. The total quantity of scraps of bone may have amounted to a wineglassful.

An inscription ran round one of the steatite vases just below the lid. The words mean: This shrine for ashes of the Buddha, the Exalted One, is the pious work of the Sakiyas, his brethren, associated with their sisters, and their children, and their wives. The thirteen words, in a local dialect of Pali, are written in very ancient characters, and are the oldest inscription as yet discovered in India. Twelve out of the thirteen are well-known words, the interpretation of which is not open to doubt. One word, rendered above by "pious work," has not been found elsewhere, and its derivation is open to discussion. The explanation here adopted as most probable was put forward by Professor Pischel of Berlin. The phrase "pious work" probably had a precise technical connotation like the English "benefaction."

The monument must have been of imposing appearance. The diameter (on the ground level) of the dome is 116 ft. For 8 ft. from the summit of the ruin it was not possible to trace the outline. At that point the outer wall, if one may so call it, of the solid dome could be traced, and had a diameter of 68 ft. The dome, therefore, sloped inwards 1 ft. for every 3 ft. in height, in other words, it was, like all the most ancient of these artificial mounds of India, a subconical form and cannot have been more than about 35 ft. high exclusive of the ornament or "tee" on the summit. We have in bas-reliefs of the 3rd century representations of what these ornaments were—small
PIQUA—PIQUET 637

square erections, like a shrine or small temple, surmounted by a canopy called from its shape a T. They were then more than a third of the height of the dome itself. The total height of this Sākiya tope will therefore have been approximately a little under 50 ft. It was probably surrounded by a carved wooden railing, but this has long since disappeared.

All such monuments hitherto discovered in India were put up in honour of some religious teacher, not in memory of royal persons, generous benefactors, politicians, or soldiers or private persons, however distinguished. And we need have no hesitation in accepting this as a monument put up over a portion of the ashes from the funeral pyre of Gotama the Buddha. The account of the death and cremation of the Buddha, preserved in the Buddhist canon, states that one-eighth portion of the ashes was presented to the Sākiya clan, and that they built a thāipa, or memorial mound, over it.1

Mr. Peppe presented the coffee and wines with specimens of the jewelry to the museum at Calcutta where they still are. He also gave specimens of the trinkets to the Asiatic Society in London.

Peppe’s original article is in the Journal of the Royal Asiatic Society for 1898, pp. 577 sqq. Comm. upon it, one or two of them sceptical, are in the same Journ. 1898, pp. 579, 588, 587, 866; 1899, p. 425; 1901, p. 358; 1905, p. 697; 1906, pp. 149 sqq. See also M. de Sarazin, Querelles de la Sâkya (1898), xxvi, 147, 233; Sylvain Levy, Journal des savants (1905) pp. 540 sqq.; and R. Pischel and R. I. Davids as quoted above.

Piquet, a city of Miami county, Ohio, U.S.A., on the Miami River and the Miami & Erie Canal, 73 m. W. by N. of Columbus. Pop. (1860), 9590; (1900), 12,172, of whom 901 were foreign-born and 457 were negroes; (1910 census), 13,588. It is served by the Pittsburg, Cincinnati, Chicago & St. Louis, and the Cincinnati, Hamilton & Dayton railways, and by inter-urban electric lines to Lima, Dayton and Covington. It has a park, a public library and a public hospital. There are quarries of blue limestone in the vicinity. The city has various manufactures, and the factories produce being valued in 1905 at $1,923,706. The municipality owns and operates its waterworks. On or near the site of Piqua was one of the principal villages of the Chillicothe division of the Shawnee tribe; the village also was called Chillicothe. It was destroyed by George Rogers Clark in 1782. A town was laid out here in 1809 under the name of Washington, and the present name, that of another division of the Shawnee tribe, was substituted in 1823. Piqua was chartered as a city in 1856. During the French and Indian War, in 1763, a battle was fought in this vicinity chiefly between the Miami, Wyandots, Ottawas and other Indian allies of the French, and the Delawares, Shawnees, Cherokees, Cataaways and other Indian allies of the English, the English allies making an unsuccessful attempt to drive the French allies from their fortified position, Fort Piqua.

See Henry Howe, Historical Collections of Ohio (Columbus, 1861).

Piquet, a game at cards, probably a development of ronfa, a game mentioned by Berni in 1526; la ronfe (included in Rabelais’s list, c. 1530) may be regarded as the same game. The point at piquet was anciently called ronfe. The Spanish name of the game was ciesos (centum, a hundred). Piquet was played in England under the name of cent, or suit, probably as early as 1530 (contemporaneously with the marriage of Mary to Philip of Spain). About the middle of the 17th century (shortly after the marriage of Charles I. to Henrietta Maria of France) the cent was dropped in England, and the French equivalent, piquet, adopted. It is played by two or three persons, with a pack of thirty-two cards—the sixes, fives, fours, threes and twos being thrown out from a complete pack. At one time the partie was the best of five games of a hundred up (a player not obtaining fifty losing a double game). But now the partie is generally determined in six hands, the player making the largest aggregate score being the winner. The number of points won is the difference between the two scores, with a hundred added for the game. If, however, the loser fails to make a hundred in six hands, the number of points won is the sum of the two scores, with a hundred for the game. Piquet played in this way is called Rubicon Piquet.

The dealer deals twelve cards to his adversary and to himself, two at a time. If the dealer places the eight undealt cards, called the "stock," face downwards on the table, the top five being for the elder hand (non-dealer) to take from first in exchange for his own. The players now look at their twelve cards before they say "seen." If one sees having been declared, if there is one, put out (without showing them) such cards as he deems advisable in order to improve their hands, and take in an equivalent number from the stock. Each player must discard at least one card. If the elder hand discards less than the five he is entitled to; if he discards more than the number the dealer has named the suit he will first lead. Each player may examine his own discard at any time during the hand; but he must keep it separate from his other cards.

The elder hand next makes a declaration of what he has in his hand.

The "point" must be called first or the right to call it is lost. It is scored by the player who announces the suit of greatest strength, four of a kind, 11 of the same suit, etc.; ace of spades, aces of each of the suits are "jacks," 11 of the same suit are "knaves," and so on. The dealer has named the suit he will first lead, or has led a card. If the younger hand elects not to look at the cards left the elder cannot see them. The younger hand must make his election before the dealer can order the cards of the suit named by the dealer has named the suit he will first lead; each player may examine his own discard at any time during the hand; but he must keep it separate from his other cards.

The elder hand next makes a declaration of what he has in his hand.

Sequences are usually called next, the elder hand stating whether the best sequence he has is "good," "equal," "equal," or "not good," as in the case of the point. Any three or more consecutive cards of the same suit held in hand constitute a sequence. The order of the cards is as follows: ace (highest), king, queen, king, nines (or the other suits); the elder hand may call for any number of cards, or whatever the cards may be, or he may call for any card face upwards. If the younger hand has a suit of more than five cards, he says "good." If the younger hand has also five cards, he says "equal" or "what do they make?" when the elder calls "equal," or "equal," or "what do they make?" when the elder calls "good." The younger hand must not inquire what the point makes unless he has an equal number of cards. If the younger hand’s five cards make less than forty-eight he says "good"; if exactly forty-eight, he says "equal"; if more than forty-eight he says "not good." The player whose point is good recons one for each card of it; if the points are equal neither player scores for point.

Sequences of four or more cards follow the same nomenclature; e.g., if he has an ace of hearts, king, queen, knave, this is called a "tiers"; if four, a "quart"; or five, a "quint"; of six, a "séxta"; of seven, a "septième"; of eight, a "huitième." A tierce of ace, king, queen is called a "tierce major"; a tierce of king, queen, knave is called a "tierce to a king" and so on. A sequence of a greater number of cards is good against a sequence of a smaller number; thus, a quart minor is good against a tierce major. As between sequences of the same kind, a sequence of higher rank is headed by the highest card is good; thus, a quart to a queen is good against a quart to a knave. Only identical sequences can be equal.

The player whose sequence is good recons one for each card of it, and ten in addition for four, or any other sequences. Of this a tierce counts three; a quart, four; a quint, fifteen; a sixième, sixteen; and so on. The elder hand’s sequence is good, he names the suit, or shows it face upwards. If the highest sequence (or the sequence first made) is not good he must discard a card, and the dealer may understand that the adversary has a sequence of intermediate value. For example, A has a quart to a queen (good), and a tierce minor. He calls and recons seven, notwithstanding that B has a quart to a eight. They have this in common. The player whose sequence is equal, neither player scores anything for sequence, even though one player may hold a second sequence of equal or inferior value.

Quatorzes and "trios" are the next calls. Quatorzes are comprised of four, four queens, four aces, four "trios" of the same suit, etc.; four fours, four fives, four sixes, or four tens, in order of value; "trios" of three of any of these. A quatorze, if good, recons fourteen; a trio, if good, recons three; one that is good establishes any smaller quatorzes or trios in his hand.

When the elder hand has done calling he leads a card. Before
playing to this card, the younger hand reckons all that he has good, stating of what cards his claims are composed, or showing the cards claimed for. The elder hand leads any card he pleases; the younger plays to it. The younger hand must suit if able; and if not, he may play trump, or any other card, whether compulsory to win the trick. The leader counts one for each card led, whether it wins the trick or not. If the second player wins the trick he also counts one. The winner of the last trick counts an ace (if the leader has not led it) as well as the trick. The trick leader is next in order of the player who wins them. They may be examined by either player.

If each player wins six tricks the cards are divided, and there is a hand then proceeds. A player who wins six tricks, he may give the "cards," and adds ten to his score. If one player wins every trick, he wins a capot, and scores forty for the cards, instead of ten.

During the play of the hand, a player is entitled to be informed as to any cards his adversary holds which he reckons as good, or has declared to be equal. A player may require his adversary to exhibit any such cards. But if a player, having played three cards and his adversary deals, and asks and is denied, as far as he has left, he need only reply "Two."

During the progress of the hand each player repeats aloud the amount of his score for the time being. At the end of the hand the periods and equal cards are announced by each player. If there is a difference in the written scores, a player's score of his own hand is deemed to be the correct one.

Example.—A (elder hand) has dealt him ace, king, knave, nine of spades; ace, queen, knave, eight of hearts; king, seven, eight of clubs; king, eight, nine of diamonds. He discards seven of spades, and nine, seven of hearts. He takes in queen of spades; ace of clubs; and seven of diamonds. B (younger hand) has seven, ten of spades; ten, nine, seven of hearts; king, queen, ten of clubs; and ace, queen, knave, ten of diamonds. B discards seven of spades, and nine, seven of hearts. He takes in queen of spades; ace of clubs; and seven of diamonds. They then have thus: A has five, B says "equal," or "what do they make?"

A "forty-nine," or "making nine." B "good."

A (counting his point) "five" and, counting his sequence, which is good, "forty-nine." B "not good."

A (leads ace of hearts and says) "ten." B "four tens, fourteen, and three queens, seventeen" (plays the ten of hearts).

A (leads remaining hearts and says) "eleven, twelve, thirteen, fourteen, ten, queen of diamonds, and repeating his score says) "seventeen."

A has now five tricks, and in order to win the cards should lead any card but a high spade. He leads king of diamonds, and says "of diamonds." B (counter) says "repiques."

A (keeps ace, knave of clubs, and repeating his score says) "fifteen, ten of spades, and two of diamonds, twenty-three."

A (wins with ace and says) "sixteen" (and leads knave, saying) "eighteen" (and then adding ten for the cards) "twenty-eight."

A then writes on his scoring card 28. B writes on his 23. 28, 56. A (counter) says "thirteen, eldest hand, and three tricks." Three scores (omitted in order to simplify the description of the game) have yet to be mentioned.

*Carle Blanche.*—If either player has no king, queen, or knave in his hand, he says "carle blanche;" and as far as he has left, he may gain a pique, for which he scores thirty.

*Repique.*—If a player scores in hand alone thirty or more before his adversary reckons anything, he gains a repique, for which he adds as far as he has left, to his score, fifty, for each repique. A player who has an equal point or sequence scores nothing for it. Therefore, if, notwithstanding the equality, a player makes thirty, in hand and play, or in hand, by scores which reckoned in order before anything his adversary can count, he gains a pique or a repique.

The order in which the scores accrue is of importance. For the sake of convenience, the elder hand finishes his reckoning before the younger begins. The scores, however, whether made by the elder or younger hand, are recorded in the following order: (1) carle blanche; (2) point; (3) sequences; (4) quadrizes and trisos; (5) points made in play; (6) the cards. This will often affect a pique or repique. Thus, a pique can only be made by the elder hand. The younger, therefore, cannot make thirty in hand and play before the elder scores one. But the one reckoned by the elder hand when he leads his first card does not prevent his being repiqued, because scores made in hand have precedence of points made in play. The elder leads his first card and counts for it before the younger reckons, simply as a convenient way of stating (placards he has any thing in hand which is good. Again, say A has a quint (good), a tierce, and a quatorze (good). He scores thirty-two in hand alone; but, if his point is not good, he does not gain a repique, because the younger hand's point is recordable. In order to prevent a predetermination of the score, each party must be aware of the score of the other. All other scores, save piques and repiques, also count towards piques and repiques. A capot does not count towards a pique, as the capot is not made in play. It is added after the trick is played, and the score of the capot is not made in play. Therefore, it is necessary that a player does not gain that hand as a penalty is not piqued or repiqued if he holds any cards which, but for the penalty, would have reckoned before his adversary reached thirty.

*Piracy,* or Perim, an island in the Gulf of Cambay, forming part of Ahmadabad district, Bombay. Formerly notorious as the stronghold of a pirate chieftain, it has attained fame among palaentologists for the large quantity of fossil remains discovered here in 1836, similar to the better-known Siwalik fauna.

**Piranesi, Giovanni Battista,** Italian engraver of ancient architectural subjects, was born in the earlier half of the 18th century, and studied his art at Rome. The great remains of that city kindled his enthusiasm and demanded portrayal.

His hand faithfully imitated the actual remains of a fabric; his invention, catchment of the esteem of the original architect, supplied the parts that were wanting; his skill introduced groups of vases, altars, tombs; and his broad and scientific distribution of light and shade completed the picture, and threw a striking effect over the whole. One engraving after another was executed with much brilliancy; and, as the work went on, the zeal of the artist only waxed stronger. In course of time it was found necessary to call in the aid of all his children and of several pupils. He did not, in fact, slake in his exertions till his death in 1778.

The plates of Piranesi, in which the severity of burin work is largely supplemented by the finer lines of the etching-needle, were copied and preserved by his son and coadjutor Francesco. They were published, to the number of about 2000, in 29 vols. fol. (Paris, 1835–1837).

**Pirano,** a sea port of Austria, in Istria, 22 m. S.W. of Trieste by rail. Pop. (1900), 13,339, mostly Italians. In addition to viticulture and the cultivation of the olive, its principal resources are ship-building and fishing. In the neighbourhood are the most extensive works in Istria for the extraction of salt from the sea-water, which produce about 50,000 tons of salt annually.

Pirano is celebrated for the victory of the Venetians over the fleet of the emperor Frederick Barbarossa in 1177. It passed under the domination of Venice in 1285 and became definitively incorporated with Austria, together with the other possessions of Venice in the Istria Peninsula, in 1815.

**Pirate and Piracy.** Sir Edward Coke (Instit. iii, 113) describes a pirate (Lat. pirata, from Gr. πυράξ, πυράχων, to attempt or attack), as hostis humani generis, and as a robber upon the sea. Sir J. Fitzjames Stephen in his Digest of Criminal Law defined piracy as follows: "Taking a ship on the High Seas or within the jurisdiction of the Lord High Admiral from the possession or control of those who are lawfully entitled to it and carrying away the ship itself or any of its goods, tackle, apparel or furniture under circumstances which would have amounted to robbery if the act had been done within the body of an English county." (cf. A. G. for Hong-Kong v. Kwok-a-Sing, 1873, L.R. 5 P.C. 179). Piracy, being a crime not against any particular state but against mankind, may be punished in the competent court of any country where the offender may be found or into which he may be carried. But, whilst the practice of nations gives to every one the right to pursue and exterminate pirates without any previous declaration of war (pirates holding no commission or delegated authority from any sovereign or state), it is not allowed to kill them without trial except in battle. Those who surrender or are taken prisoners
PIRATE AND PIRACY

must be brought before the proper tribunal and dealt with according to law.

Piracy has been dealt with in a large number of English statutes, from 1536 down to the Territorial Waters Jurisdiction

Act 1878 (41 & 42 Vict. c. 73), which provided for the maintenance of the existing jurisdiction for the trial of "any act of piracy as defined by the law of nations."

During the Spanish-American War the Spanish government issued (1898) a decree declaring that "captains, masters and officers of vessels, which, as well as two-thirds of their crew, are not American, captured while committing acts of war against Spain, even if they are provided with letters of marque issued by the United States" would be regarded and judged as pirates. This was not in accordance with the international practice on the subject.

A public ship or one which is entitled to fly the flag of a belligerent and navigates under the cover of state papers, by the very sense of the term, is not a pirate. Again, during the Russo-Japanese War, the word "piracy" was freely applied in British newspapers to the seizure of the "Malacca" and other vessels held up by the "Peterburg" and "Smolensk," two cruisers belonging to the Russian Black Sea volunteer fleet, which in July 1904 passed as merchantmen through the Bosphorus and Dardanelles and were transformed to their real character on the open sea. The application of the term in this case was equally inaccurate.

The conversion of merchant into war ships was one of the subjects dealt with by the second Hague Conference (1907), but it was agreed that "the question of the place where such conversion is effected remains outside the scope of the agreement."

Piracy is essentially a crime under international law, and although any state may apply its penalties to its own subjects by analogy, as was done by Great Britain and the United States in connexion with the repression of the slave trade, they cannot be lawfully applied to subjects of other states. (T. Ba.)

Historical Sketch.—It has at all times been more difficult to enforce good order on the sea than on the land; or perhaps we ought to say that the establishment of law and order on the sea has in all ages of the world's history followed, but has not accompanied, and has still less preceded, the creation of a good police on the land. The sea robber, or pirate, cannot make a profit from any part of his booty except the food which he consumes, or the vessels which he may use, unless he can find a market. But so long as he is sure that he will somewhere meet a purchaser for the goods he has taken by violence, he has every encouragement to pursue his trade. Therefore from the times described in the Odyssey, down to the days when Sir Henry Keppel sailed in H.M.S. "Dido" to suppress the pirates of Borneo, and when Rafael Brooke of Sarawak co-operated with the British in Borneo, we find that the prevalence of piracy and the suppression of it have been closely dependent on the efforts made to rout it out from its lurking-places on the coast, and the degree of success achieved.

Very different types of men have been named pirates. They have in fact been so unlike that to class them all together would be in the last degree unjust. The Greek in the youth of the world, and the Malay of Borneo in the 10th century, knew of no rule of morals which should restrain them from treating all who lay outside the limits of their city or their tribe as enemies, to be traded with when strong and plundered when weak. They might be patriotic, and law-abiding men towards the only authority they recognized. Their piracy was a form of war, without close moral analogies to the seizure of Silesia by Frederick the Great, the attempted seizure of Spain by Napoleon, or of the war stories of this kind of venture, with its deceitful preliminary success and its final disaster, may fairly be compared with the fall of Ulysses and his companions on the Cicones, as told in the ninth book of the Odyssey. Yet it would be highly uncritical to class Ulysses or Napoleon with Captain Avery, or Captain Kidd, or Bartholomew Roberts. We are not here concerned with the legal aspects of piracy, but with the true character of the persons to whom the name pirate has been applied at various times. The term was applied by the Romans to the adventurers against whom Pompey was commissioned to act by the Gabinian Law, by the English of the 9th and 10th centuries to the Vikings, and by the Spaniards to the English, French and Dutch who were found sailing beyond the line. Sufferers by naval commerce-destroyers call it "a piratical form of warfare." But the pirates of the Roman Republic were no mere "gang of robbers." They were the victims of a time of conquest and "general overture"—the ruined men of all nations, the hunted refugees of all vanquished parties, everyone that was wretched and daring—and where was there not misery and violence in this unhappy age? It was no longer a gang of robbers who had hocked together, but a compact soldier state, in which the freemasonry of exile and of crime took the place of nationality, and within which crime redeemed itself, as it so often does in its own eyes, by displaying the most generous public spirit. Such men were akin to the fuorussili of Italian history or the Dutch Beggars of the Sea, the victims of party strife in the cities, who took to the sword because they had no other resource. Mutatis mutandis we may say as much for the intruders beyond the line, whom history calls the "Buccaneers" (q.v.). The "Vikings" (q.v.) were a portion of the Barbarian invasions. The "Barbary Pirates" (q.v.) stand apart. As for the piratical character of the commerce-destroyer, or privateer—why are we to brand Captain Fortunatus Wright, the Englishman who captures a French merchant ship, or Captain Robert Surcouf, the Frenchman who captures a British East Indiaman, as piratical, and not make the same reproach against Admiral Lord Howe, or Admiral Don Luis de Córdoba, who with a fleet captures whole convoys?

The pirate pure and simple is that member of an or cuttry community who elects to live on the sea, by violence and robbery, making no distinction between his own city or tribe and any other. The old adage that "war makes thieves and peace hangs them" has ever been peculiarly true of the sea. War has always been conducted there by the capture of an enemy's property, and by division of the spoil. A portion of the naval forces of all nations has been composed of privateers, letters of marque or corsairs, who plundered with a licence. They have ever found a difficulty in drawing the line between enemy and neutral; when peace returned some of them found it hard to be content with honest wages earned by dull industry. Nelson declared that all privateers were no better than pirates. He was born out by the experience of Great Britain, which at the beginning of the Seven Years' War had to take strong measures to repress the excesses of its privateers, and to hang a good few of them as mere pirates. The pirates suppressed by Pompey did not all submit to remain in the settlements he made. Some continued to rob at sea. If we can trust the Pastoral of Longus, and the other Greek romances, the pirate was a known type even under the Roman peace, but it is highly probable that he was more of a stock literary figure than a reality. Before the Roman peace, and during long centuries after it had been shattered, piracy was common. It grew out of a state of war. In modern times—even down to 1815—a recrudescence of piracy has followed regular hostilities. But there are other conditions which have a material influence, such as the need for a lurking-place and for a receiver of the plundered goods. An archipelago provides the best lurking-places, and next to it a coast of many inlets. Therefore the Greek Islands, the British Isles, the Antilles, the Indian Ocean, the coast of Cilicia in Asia Minor, of Dalmatia, of Malabar and of Norway, have all at one time or other, and some of them for centuries, been haunts of pirates. The convenience of the place had to be completed by the condition of the market. In the ancient world, and the middle ages, the market never failed. One city or tribe had little care for the sufferings of another. The men of the Cinque Ports who plundered the men of Yarmouth knew that their own craftsmen would never call them to account, and therefore they had a safe refuge. Even when the medieval anarchy had come to an end on land, the sea was lawless. When peace was made with Spain after the death of Queen Elizabeth there were many who could not settle down to a life of industry. Some took the
PIRATE AND PIRACY

plain course of betaking themselves to Algiers or Sale. But
there were many who prowled nearer home. Sir William
Monson, in his Naval Tracts, tells how he was sent in 1605 to hunt
pirates out of the Shetlands and the Hebrides. He found none
at sea near Scotland, but some unemployed, whom he shipped
and used as guides and informers, on the coast of Ireland. At
Broad Haven he discovered an Irish gentleman of the name of
Cormat (presumably Cormac) living in some dignity. His
house was "the head of all pirates," and their captains
were the lovers of his daughters. Monson found agents
of merchants of London and of Galway, who came to buy the goods
which the pirates had to sell at a bargain. He put that interest
family under the gallows, and frightened them into turning
to piracy. It was his boast that he had cleared the
Irish coast of pirates, but we know that they were common
in the reign of Charles I., and that under the name of "sea
Tories" they abounded during the Civil War both in Ireland in
and in the Scilly Isles. Their existence was probably the
weakness of the government, which when piracy became very
rampant took the disastrous course of offering pardon to all
who would come in by a certain date. As a matter of course
many did, and when their booty was spent returned to their
piratical trade. Monson says that the pirates he caused to be
executed had already tasted of the king's mercy. While there
were friendly harbours to anchor in, purchasers to be met and a
very fair prospect of a free pardon, piracy was not likely to
cease.

As the 17th century drew on the law and the police became
too strong for such persons as Mr Cormat at Broad Haven,
and his pirate friends. But the pirate class did not cease. It was only driven to a wider field of operations—to a field
which in fact stretched from the Red Sea to New England.
On this wide portion of the earth's surface everything combined
to favour the pirate. In the West Indies there was a "well-
head" of immense capacity. Spain was forced late and reluc-
tantly to recognize the legitimacy of any foreign settlement.
She would rather put up with the lawless adventurers known
as the "Brothers of the Coast" and the "Buccaneers" than co-operate with foreign governments to suppress them. Even
when she renounced her full pretensions, several of the islands
remained unoccupied except by the lingering remnants of the
native races. Swine and cattle had been let loose on many of
them, and had multiplied. The turtle was abundant and
succulent. There was no want of food. A population with
predatory instincts had been formed in the early days of hostile
settlement and buccaneering. Jamaica was full of the so-called
"private men-of-war" whose doings are prominent in the corre-
cspondence of the early governors, who were not uncommonly their associates. Add to this that the commercial
policy of Spain denied to her colonists the privilege of trading
with foreigners, and yet that she could not supply their needs
herself. Hence arose a smuggling trade which had affinity with
piracy. The lawless trader was not liable to be asked awkward
questions, as to the origin of his cargo, by the Spanish American
who purchased it on the sly for money or by barter. Nor were
any questions asked him when he brought his cargo to Jamaica,
San Domingo, the Carolinas, New England or even Europe.
In the decay of Spain her navy was not to be feared. But it
was not the commercial policy of Spain alone which helped the
pirate. Great Britain, and France also, insisted that their
colonists should trade exclusively with or through them. The
colonists were always ready to buy "good cheap" from the
smuggler, and never ask him whether the East Indian produce
—tea, silk, spices and so forth—were for sale were purchased
or plundered in the Red Sea or on the coast of Malabar or
Ceylon. Add to all this that the police and patrol work of regular navies was but superficially done even in peace, and
hardly at all in war, and that in the British colonies there
was no judicial machinery for trying pirates till the 11th and
12th years of William III. (1700, 1701), and it will be seen that
all the conditions favoured the pirate. In the East the
decadence of the Mogul Empire was plunging India into anarchy,
to suppress pirates in the Eastern seas, brought deserved discredit upon them. The decision made on the advice of Burchett, the secretary of the admiralty, to offer a pardon to all who would surrender by a given date—for all pirates committed before the 30th of April to the east of the Cape of Good Hope, and the 30th of June 1699 to the west—was an error. It induced many to come in, but it also gave all pirates the hope that they would in the future be provided with similar means of escape. The establishment of admiralty courts in the East Indies and America and the despatch of warships were more effectual methods. Yet it was long before piracy was thoroughly checked; indeed the signing of the Peace of Utrecht was followed by a recurrence of this form of crime. The privateers who swarmed in the West Indies and, as long as the war lasted, used, in the phrase of the time, to join the squadrons of war-ships "on the plundering account" did not settle down to dull industry. They deserted themselves into a species of pirate republic, with its capital at Providence in the Bahamas. In 1718 a special force had to be sent against them under Woodes Rogers, who is best remembered now for having taken Alexander Selkirk from the island of Juan Fernandez, in the course of a privateering voyage into the Pacific with the "dude" and "duchess" of Bristol. Rogers broke up the Providence settlement, and did a similar piece of service on the coast of Madagascar. Piracy did not, however, die. The Aisiento (q.v.) Treaty having given Great Britain a monopoly of the slave trade with Spanish America, the monopolis, i.e. the South Sea Company and Royal African Company, were of course subject to the competition of interlopers. The interlopers were the natural friends of the pirates, who divided their activity among the Antilles and the west coast of Africa, plundering in the second, seeking and re-fitting, not perhaps further plunder, in the first. The most notorious of these freebooters was Bartholomew Roberts, who was introduced to piracy by Howell Davis. Roberts was the nearest known approach to the pirate of romance, ostentatious, brave, not without touches of generosity. He was killed in action with Captain Chaloner Ogle, of H.M.S. "Swallo\textsuperscript{w}," on the coast of Africa, in 1722.

As the American colonies grew more settled piracy became intolerable to them. Yet it lingered on the coast of North Carolina, where the pirates could either terrorize the scattered inhabitants, or be encouraged by dishonest officials. Here flourished the grotesque brute known as Blackbeard, Edward Teach, till he was run down and slain by Lieutenant Mills of the British Navy in 1718. It was noted that several of those who had suppressed him afterwards went "a-pirating" themselves. So strong was the piratical tradition of the New World that even men of some standing fell into it. "Major" or Captain Stede Bonnet, who was condemned and executed at Charleston, South Carolina, as a pirate, in 1718, was a gentleman of some property in Barbadoes, who first ventured to sea in a ship of his own. Stede Bonnet had taken advantage of an act of grace, had come in on a proclamation, and had returned to a pirate's life. The last great explosion of piracy in the West Indies followed the peace of 1713. Here again we find the old conditions—privateers and other unsettled men, the safe lurking-place and the receiver. The refuge and the market were supplied by the Spanish colonies, which were plentifully stocked by their revolt against Spain. The pirates were able to masquerade as "patriot" navies. The sloth and corruption of Spanish captains-general of Cuba were no less favourable to the pirates. The south coast of the island became a haunt of these villains till the British and American governments were driven to combine for their suppression. When they had been followed into their hiding-places and their vessels sunk, they took to brigandage on land, and were garrotted by the Spanish authorities in self-defence. The piracy of the Greek islands went on to later years, and the Malays were not tamed till nearly 1850. On the coast and the rivers of China piracy was and is endemic, but the sailing junk has no chance with the modern steamer. When cases of piracy have occurred in the Straits of Malacca or in the China seas, by which Europeans have been the sufferers, the crime has generally been perpetuated by men who shipped as passengers or as crew, and who surprised the vessel. The pirate has been as useful to the author of modern tales and poems as to the writers of the Greek romances. When he is seen in authentic evidence he is found to have been for the most part a pitiful rogue. His gains were but small. A share of £200 was wealth to a mere sailor, and one of £1000 wealth beyond the dreams of avarice. He rarely sought a warship if he could help it, and indeed nothing is more surprising than his readiness to surrender when the fate before him was the gallows.

Authorities—The pirates of the world are admirably dealt with in Mme. Eliza Robert's History of the Modern Pirates, London, Naval Tracts in Churchill's Voyages, 1744-1746, and in the edition of the Navy Record Society (1902). But the best accounts are to be found in the State Trials, vols. xii., thirteen (London, 1812). Captain Charles Johnson's General History of the Pirates (London, 1724) must be used with caution. He does not mention many pirates, who, having come in on a proclamation, were free to talk, but he cannot always be reconciled with authentic records. The Documents relating to the Colonial History of the State of New York (Albany, 1856-1858) contain many curious details. For the eastern seas, the Compendious History of the Indian Wars; with an account of the Rise, Progress, Strength and Forces of America, the Pirate, &c., by Clement Downing (London, 1737) is a must. (D. H.)

Pirke Aboth.
The penultimate tract of the fourth part of the Mishnah is the booklet of proverbs in five chapters called Massecheth Aboth (tractatus patrum), better known with a sixth chapter as Pirke Aboth (capitula patrum). For Pirke Aboth in English see The Authorized Daily Prayer Book of the united Hebrew congregations of the British Empire, with a new translation by the Rev. S. Singer. The six chapters are there appointed to be read one on each Sabbath afternoon between Passover and New Year. Formerly they were read, in places at least, on the six Sabbaths between Passover and Pentecost only. The subsections of the chapters are hereinafter numbered as in the Authorized Prayer Book.

Chapters i., ii.—The Mosaic succession has first to be established. Moses (i. 17-20) having received the law, handed it over to Joshua, the Elders (Josh. xxi. 31), the Prophets and the men of the Great Synagogue, from one of the last of whom, Simon Justus, it was received by Antigonus of Socho. Next are named (ii. 4-15) without any title, as links in the chain of tradition, five teachers, the last Hillel and Shammai, elsewhere in the Mishnah called mundi patres (Surenh. iv. 324). Rabban Johanan ben Zacchai (ii. 9) "received from Hillel and Shammai." Sayings of Rabban Gamaliel (i. 1-7), of Rabban Gamaliel II. and Hillel, who closes the sequence. Chapters ii., iii.—Maxims of the numerous authorities, mostly Mishnah teachers and called Rabbis (Matt. xxii. 7 seq.; J. F. p. 27), not in exact chronological order.

Chapters v., vi.—Chap. v. which is sui generis, is presumably of later date. The whole of it, from the end, it combines historical, legendary and didactic elements. It touches upon the miraculous and its place in nature (v. 9). In form it is a series of numbered groups of things, from the ten creative sayings of Moses (the Ten Words) to the ten "sayings of the disciples of Balaam and Abraham." R. Jacob ben Shimon's commentary makes Abodoth end with the saying of Jehudah ben Tema (v. 23). "Be bold as a leopard, and swift as an eagle, and fleet as a hart, and strong as a lion, and as the king of the heaven." Chapter vi., on acquisitio legis, is thought to have been added for use on the last of the six sabbaths above-mentioned (Strack, J. F. Ap. p. 61). In some manuscripts there are seven chapters.

Pirke Aboth serves as a primer to the student of rabbinic Judaism. For the most part in simple Hebrew, it has a few sayings in Aramaic (i. 13-ii., 7, v. 25, 26) and some adopted Greek words, as paraclete (iv. 13; Philo). He who would be pious should fulfil the dicta of Aboth (Baba Kam. 30a). It gives favourite aphorisms of leading Jewish teachers who flourished in or before the earliest Christian centuries, and supplies material for some interesting illustrations of the New Testament. Too heterogeneous to be represented by a few extracts, the collection

XXI. 21

11
must be read through to be appreciated. Among the sayings of Hillel we miss the best known one, *What is hateful to thee do not, &c. (J. F. p. 142), with which there may now compare Exod. xxxii. 16; Heb. "Know (?) thy neighbour as thyself, and consider what thou hastest." Of the precept, "Make a fence to the Torah" (i. 17; c. iii. 17) it may be said that "everything is therein." As a doctrine of development and as an ethical principle it is reflected in Clement of Alexandria's view of philosophy as a δραγμον of the vineyard (Strom. i. 20), and Polycarp's saying, "He that has love is far from all sin." The use of Aboth in the synagogue stamps it as authoritative, and, with its intrinsic excellence, has led to its being "the most popular of all rabbinical writings." For midrashic comments upon it see the Aboth of Rabbi Nathan (ed. S. Schechter, Vienna, 1887), or the rendering of it (new ed., New York, 1900) in M. L. Rodkin's translation of the Babylonian Talmud into English. (See also APOCRYPHAL LITERATURE, § Old Testament, II. d.)

BIBLIOGRAPHY.—Aboth is included in editions of the Mishnah and the Talmud Babli, and in many prayer-books. For separate editions from about 1484–1485, see Moritz Stein Schneider's Bodelein Catalogus, col. 228–239, 2785, and other works cited in Herm. L. Sack's very useful περίπτωσις Die Sprüche der Väter (ed. 3, 1901). N. Levison's "Vaterrede der Feier von Pirna", 1897, referred to above as J.F., a separate Appendix (1900) describes or enumerates manuscripts of Aboth—and Jewish Encyclopedia, art. "Aboth." (C.T.)

PIRMASENS, a town of Germany, in the Bavarian Palatinate, 40 m. by S. of Spiers, on the railway from Biebelach to Pop. (1901) 34,002. The only noteworthy buildings are the town-hall and the principal Evangelical church, which contains a fine monument to Louis IX. (d. 1270), landgrave of Hesse-Darmstadt, who made the town his residence. The staple industry is the production of boots and shoes; but musical instruments, leather and machines are also manufactured. Pirmasens owes its name to a St Pirmin, who is said to have preached Christianity here in the 8th century. It originally belonged to the count of Hanau-Lichtenberg, but passed to Hesse-Darmstadt in 1736. In September 1793 the Prussians gained a victory here over a body of French troops.

PIRMEZ, OCTAVE (1832–1883), Belgian author, was born at Châtelineau in 1832. He belonged to a well-known Belgian family, and his cousin, Édouard Pirmez, was distinguished for his works on literary and political subjects. He lived an uneventful life at his château of Acoz, in Hainaut, where he died in May 1883. Pirmez was an ardent admirer of the French romanticists. His works include *Les Feuilles pensées* (1862); *Les Edicts de solitude* (1866); *Rêve, Souvenirs d’un frère* (1882); *Heures de philosophie* (1884); and the posthumous *Lettres à José* (1884). These books form a history of his emotional life, and reveal an extreme melancholy.

See *Vie et correspondance d’Octave Pirmes* (1888), by Adolphe Siret and José de Coppin.

PIRNA, a town in the kingdom of Saxony, on the left bank of the Elbe, 11 m. above Dresden, and on the railway to Bödendorf and Prague. Pop. (1901) 19,220. The town is regularly built, with promenades covering the site of the old fortifications; the most notable edifices are the fine Gothic parish church, built in the 16th century and restored in 1850, and the old town-hall. Excellent sandstone is found on both banks of the Elbe. There are manufactures of glass, machinery, cigars, pottery and enamelled goods; and there is a trade in grain, fruit and timber, mainly carried on by river, and in shipbuilding. Pirna, originally a Saxon town, was for a long time in the German possession of Bohemia and Meissen, but it became permanently united with the latter, and thus with Saxony, in 1405. The Sonnenstein, a fortress on a commanding eminence above the town, was erected in the 16th century on the site of an older castle by the elector of Saxony, Augustus I. It was once considered the most important fortress on the Elbe, and successfully withstood the Swedes in 1630, but it was captured and dismantled by the Prussians in 1738, and in 1814 was occupied by the French.

See R. Hofmann, *Zur Geschichte der Stadt Pirna* (Pirna, 1891); E. Küngel, *Führer durch Pirna* (Pirna, 1888); the *Urkundenbuch der Städte Dresden und Pirna*, edited by C. F. von Posern-Klett (Leipzig, 1875); and the publications of the *Verein für Geschichte der Stadt Pirna* (Pirna, 1897 seq.).

PIRGOUE, or PIRGAU (the French and Spanish forms respectively of the Italian word for this type of vessel; it has at various times taken many corrupt forms, e.g. porigaue, purgauag, pettugger, bugauger, pettuga)—originally the native name of a vessel made by hollowing out the trunk of a tree, a "dug-out"; hence applied to many different developments of this type of vessel used in the West Indies and along the American coast. An early improvement was to split the "dug-out" into two sections and insert a flat bottom of planking to widen it; another form had a leeboard, was decked in at either end, and had two masts.

PIRON, ALEXIS (1689–1773), French epigrammatist and dramatist, was born at Dijon on the 9th of July 1689. His father, Aimé Piron, was an apothecary, who wrote verse in the Burgundian patois. Alexis began life as clerk and secretary to a banker, and then studied law. In 1719, when nearly thirty years old, he went to seek his fortune at Paris. An accident brought him money and notoriety. The jealousy of the regular actors produced an edict restricting the Théâtre de la Foire, or licensed booths at fair times, to a single character on the stage. None of the ordinary writers for this theatre would attempt a monologue-drama for the purpose, and Piron made a great success with a piece called *Arlequin Découcou*, representing Découcou immediately after the Deluge, amusing himself with recreating in succession the different types of man. In 1728 he produced *Les Fils ingrats* (known later as *L'École des pères*) at the Comédie Française. He attempted tragedy in *Callisthène* (1730), *Gustave Vasa* (1733) and *Fernand Cortès* (1744), but none of these succeeded, and Piron returned to comedy with *La Métromanie* (1738), in which the hero, Damis, suffers from the verse mania. His most intimate associates at this time were Mlle Quinault, the actress, and her friend Marie Thérèse Quenaudon, known as Mlle de Bar. This lady was slightly older than Piron and not beautiful, but after twenty years' acquaintance he married her in 1741. He died on the 21st of January 1773, in his eighty-fourth year. He was elected in 1753 to the Academy, but his enemies raked up a certain *Ode à Priape*, dating from his early days, and induced Louis XV. to interpose his veto. Piron however was pensioned, and during the last half-century of his life was never in any want. His best title to remembrance lies in his epigrams. The burlesque epithalum on himself, in which he ridicules the Academy—

"Ciglit Piron, qui ne fut rien.
Pas même académicien"
—is well known, while many others are as brilliant. Grimm called him a "machine à saillies."

Piron published his own theatrical works in 1758, and after his death his friend and literary executor, Rigoley de Juvigny, published his *Œuvres complètes*. M. Bothomme produced a critical edition in 1850, completed by *Poèmes choisis et pièces inédites* in 1879.

PIROT (Turkish Shehr-Keç), a Servian town, 124 m. from the Bulgarian frontier at Tsaribrod, on the railway line between Nish and Sofia. Pop. (1900) 10,428. Piroț is the seat of the prefecture for the department of the same name, with a tribunal, several schools and a custom-house. It is the only proper industrial town in Servia, having numerous small factories for the manufacture of thin cloth (skoalj), woollen braided (gajdan), and especially carpets. Its carpets have a great reputation in the Balkan Peninsula for their quaint designs, durability and softness of colour. Piroț has a medieval fortress, believed to have been built on the site of the Roman fortress Quimedava, on the military road leading from Old Naissus to Philippopolis. The town is of great strategical importance, for which reason the Russian plenipotentiaries at the Berlin congress (1878) stubbornly tried to include it within the Bulgarian frontier, while Austria and some other Powers insisted that it should be given to Servia. In the war between Servia and Bulgaria in 1885 the Bulgarians occupied and held it until the conclusion of peace.
PIASA a town, archiepiscopal see and capital of a province of the same name, Tuscany, Italy, on the Arno, 7 m. from the sea and 49 m. west of Florence by rail. Pop. (1881), 42,779; (1902), 61,279. It still retains its ancient walls, 62 m. in circuit, and is defended by a citadel on the south-west. The principal streets run alongside the river, and are lined with fine buildings. Besides the cathedral, the baptistery and the famous leaning tower, the city possesses several notable churches, as the Renaissance church of the Tuscan order of St Stephen, built in 1562 from plans by Vasari; San Niccolo, with a four-storeyed tower (1230), built by Niccola Pisano, and the tomb of John of Swabia, the partricide; Santa Caterina (1202); Santa Maria della Spina, in the Italo-Gothic style, built in 1230 and restored in 1872; San Sepolcro, erected in 1159 by Diotisalvi; San Francesco, with frescoes by Taddeo Gaddi; and the basilica of San Michele (1018). Amongst the secular buildings may be mentioned, the palatial palace; the archiepiscopal palace; the palace of the other of St Stephen, built by Niccola Pisano and reconstructed by Vasari; the Upezzinghi (formerly Lanfreducci) palace, built of Carrara marble in 1590; the Lanfranchi, Agostini and other palaces; the university (1472); a large hospital (1528); and fine market halls. There are statues to Cosimo I. (by Francavilla), Archduke Leopold, and Ferdinando I. The city possesses also an academy of the fine arts, with a gallery of paintings; and the university a library of 120,000 volumes, a natural history museum, botanical garden and agricultural schools. The university, founded in 1338, has faculties of law, medicine, mathematics and philosophy and literature, and is to this day one of the most famous in Italy.

The architects of the cathedral were Boschetti and Rinaldo, both Italians, probably Pisans. It is in plan a Latin cross, with an internal length of 311 ft. and a breadth of 252 ft. The nave, 109 ft. high, has double vaulted aisles and the transverse single aisles; and at the intersection of nave and transepts there is a cupola. The basilica is still the predominant type, but the influence of the cathedral church of Constantinople and the mosque is also apparent. The pillars which support the nave are of marble from Elba and Giglio; those of the side aisles are the spoils of ancient Greek and Roman buildings brought by the Pisan galleys. Externally the finest part of the building is the west front, in which the note struck by the range of arches running round the base is repeated by four open arcades. Of the four doors three are by John of Bologna, who was greatly helped by Francavilla, Tacca and others; that at the north is much surpassed in beauty to be the work of Bonanno. Of the interior decorations it is enough to mention the altars of the nave, said to be after designs by Michelangelo, and the mosaics in the dome and the apse, which were among the last to be decorated by the Byzantine artists. The cathedral was consecrated only in 1278, and married in the 14th century by the introduction of Gothic details. The building is a circle 100 ft. in diameter, and is covered with a cone-surmounted dome 190 ft. high on which stand the statues of the two saints. The lowest range of the arches consists of twenty columns and the second of sixty; and above this is a row of eighteen windows in the same style separated by as many pilasters. In the interior, which is supported by four plasters and eight columns, the most striking features are the octagonal font and the hexagonal pulpit, erected in 1260 by Niccola Pisano. The campanile or "leaning tower of Pisa" is a round tower, the noblest, according to Freeman, of the southern Romanesque style. In height, at the 36th and 37th floors, it is almost as though the top about half as much, they are constructed throughout of marble. The basement is surrounded by a range of semicircular arches supported by fifteen columns, and above this rise six arcades with thirty columns. The lower stories of the foundations have a much smaller diameter than the rest of the tower, and has only twelve columns. The height of the tower is 179 ft., but the ascent is easy by a stair in the wall, and the visitor hardly perceives the inclination till he reaches the top and from the lower edge of the gallery looks down along the shaft receding to its base. The tower leans or deviates from the perpendicular, to a striking extent, which has gradually increased; it was 15 ft. out of the perpendicular when first built, and it has been 17 ft. since that time. There is no reason to suppose that the architects, Bonanno and William of Innsbruck, intended that the campanile should be built in an oblique position; it would appear to have assumed it while the work was still in progress. In the 14th century, a dome, diameter 180 ft., was added to the tower, to support the dome. The Campo Santo, lying to the north of the cathedral, owes its origin to Archbishop Ubaldo

1 In Strabo's time it was only 2 m. away, but the increase of the delta at the mouth of the river has since then pushed forward the coast-line.
brother and son, or, as some authorities aver, a wife and son, prisoners in their hands. Sardinia continued to be governed by two "judges" who were like petty sovereigns, but were now subject to the sway of Pisa. This was the primary cause of the jealousy of the Genoese, and of the wars afterwards made by them upon Pisa and carried on until its power was crushed. Meanwhile the Pisans flourished more and more, and continued hostilities against the Saracens. In 1062 their ships returned from Palermo laden with spoil. Thus it is not surprising that Pisa should have already had its own code of laws (Consuetudini di mare), which in 1075 were approved by Gregory VII. and in 1081 confirmed by a patent from the emperor Henry IV., a document which mentions for the first time the existence of a magistrature analogous to the consuls of the republic, although the latter, according to some writers, already existed in Pisa as early as the year 850; the point, however, is doubtful, and other writers place the first authentic mention of the consuls in the year 1094. The oldest of Pisan statutes still extant is the Breve dei consoli di mare of 1162.

In 1099 the Pisans joined in the second crusade, proved their valour at the capture of Jerusalem, and derived many commercial advantages from it; for within a short time they had banks, consuls, warehouses and privileges of all kinds in every Eastern port. Thus, while the commune of Pisa was still under the rule of the marquises of Tuscany, all negotiations with it were carried on as with an independent state officially represented by the archbishop and consuls. The aristocrats were the dominant party, and filled the highest offices of the republic, which, in the 12th century, rose to great power, both on sea and land, by its wars with the Lucchese, Genoese and Moslems.

In 1110 Pisa made peace with Lucca after six years of continuous hostilities. And in the years 1113 and 1115 it achieved a still greater enterprise. The Pisan fleet of three hundred sail, commanded by the archbishop of Pisa, St. Felix, attacked and captured the Balearic Isles, with as many as 20,000 Christians who were said to be held captive by the Moslems, and returned loaded with spoil and with a multitude of Christian and Moslem prisoners. The former were set at liberty or ransomed, and among the latter was the last descendant of the reigning dynasty. The chief eunuch who had governed Majorca perished in the siege. Immediately afterwards the fourteen years' war with Genoa broke out. The two republics contested the dominion of the sea, and both claimed supreme power over the islands of Corsica and Sardinia. A papal edict awarding the supremacy of Corsica to the Pisan church proved sufficient cause for the war, which went on from 1118 to 1132. Then Innocent II. transferred the supremacy over part of Corsica to the Genoese church, and compensated Pisa by grants in Sardinia and elsewhere. Accordingly, to gratify the pope and the emperor Lothair II., the Pisans entered the Neapolitan territory to combat the Normans. They sided in the vigorous defence of the city of Naples, and twice attacked and pillaged Amalfi, in 1135 and 1137, with such effect that the town never regained its prosperity. It has been said that the copy of the Pandects taken by the Pisans from Amalfi was the first known to them, but in fact they were already acquainted with those laws. The war with Genoa never came to a real end. Even after the retaking of Jerusalem by the Moslems (1187) the Pisans and Genoese again met in conflict in the East, and performed many deeds of valour. They were always ready to come to blows, and gave still more signal proofs of their enmity during the Sicilian War in behalf of the emperor Henry VI. From that moment it was plain that there could be no lasting peace between these rival powers until the one or the other should be crushed. The greatness and wealth of the Pisans at this period of their history is proved by the erection of the noble buildings by which their city is adorned. The foundations of the cathedral were laid in 1063, and its consecration took place in 1118; the baptistery was begun in 1152, and the campanile (the famous leaning tower) in 1174. And all three magnificent structures were mainly the work of Pisan artists, who gave new life to Italian architecture, as they afterwards renewed the art of sculpture.

It is asserted by some writers, especially by Tronci, that in the 12th century Pisa adopted a more democratic form of government. But in fact the chief authority was still vested in the nobles, who, both in Pisa and in Sardinia, exercised almost sovereign power. They formed the real strength of the republic, and kept it faithful to the empire and the Ghibelline party. The Guelph and popular element which constituted the force and prosperity of Florence was hostile to Pisa, and led to its downfall. The independence of the former city was of much later origin, only dating from the death of Countess Matilda (1158), but it rapidly rose to an ever-increasing power, and to inevitable rivalry with Pisa. Owing to the political and commercial interests binding Florence to the Roman court, the Guelph element naturally prevailed there, while the growth of its trade and commerce necessarily compelled that static to encroach on waters subject to Pisan rule. And, although Pisa had hitherto been able to oppose a glorious resistance to Genoa and Lucca, it was not so easy to continue the struggle when its enemies were backed by the arms and political wisdom of the Florentines, who were skilled in obtaining powerful allies. The chroniclers ascribe the first war with Florence, which broke out in 1222, to a most ridiculous motive. The ambassador of the rival states in Rome are said to have quarrelled about a lapdog. This merely shows that there were already so many general and permanent reasons for war that no special cause was needed to provoke it. In 1228 the Pisans met and defeated the united forces of Florence and Lucca near Barga in the Garfagnana, and at the same time they despatched fifty-two galleys to assist the Genoese. And it was this expedition which renewed hostilities with the Genoese on account of Sardinia. The judges who governed the island were always at strife, and, as some of them applied to Pisa and some to Genoa for assistance against one another, the Italian seas were once more stained with blood, and the war burst out again and again, down to 1259, when it terminated in the decisive victory of the Pisans and the consolidation of their supremacy in Sardinia. But meanwhile Florence had made alliance with Genoa, Lucca, and all the Guelph cities of Tuscany against its Ghibelline rival. The pope had excommunicated Frederick II. and all his adherents. And, as a crowning disaster, the death of Frederick in 1250 proved a mortal blow to the Italian Ghibelline cause. Nevertheless, the Pisans were undaunted. Summoning Siena, Pistoia and the Florentine exiles to their aid, they boldly faced their foe, but were defeated in 1254. Soon after this date we find the old aristocratic government of Pisa replaced by a more popular form. Instead of the consuls there were now twelve elders (anexiani); besides the podestà, there was a captain of the people; and there was a general council as well as a senate of forty members. The rout of the Tuscan Guelphs on the field of Montepulciano (1260) restored the fortunes of Pisa. But the battle of Benevento (1266), where Manfred fell, and the rout of Tagliacozzo (1268), holding the ruin of the house of Hohenstaufen in Italy and the triumph of that of Anjou, were fatal to Pisa. For the republic had always sided with the empire and favoured Conradin, whose cruel end struck terror into the Ghibelline faction. The pope hurled an edict against the Pisans and tried to deprive them of Sardinia, while their merchants were driven from Sicily by the Angevins. The internal condition of the city was affected by these events. Owing to the increasing influence of the Guelph and popular side, to which the more ambitious nobles began to adhere for the furtherance of personal aims, the aristocratic Ghibelline party was rapidly losing ground. The first man to step to the front at this moment was Count Ugolino della Gherardesca of the powerful house of that name. He had become the virtual head of the republic, and, in order to preserve its independence and his own sway, inclined to the
Guelphs and the popular party, in spite of the Ghibelline traditions of his race. He was supported by his kinsman Giovanni Visconti, judge of Gallura; but almost all the other great families vowed eternal hatred against him, and proclaimed him a traitor to his party, his country and his kin. So in 1274 he and Visconti were driven into exile. Both then joined the Florentines, took part in the war against their native city, and laid waste its surrounding territories. In 1276 the Pisans were compelled to agree to very grievous terms—to exempt Florentine merchandise from all harbour dues, to yield certain strongholds to Lucca, and to permit the return of Count Ugolino, whose houses they had burnt, and whose lands they had confiscated. Thus the count again became a powerful leader in Pisa. Visconti, however, was dead.

This was the moment chosen by Genoa for a desperate and decisive struggle with her perpetual rival. For some years the hostile fleets continued to harass each other and engage in petty skirmishes, as if to measure their strength and prepare for a final effort. On the 6th of August 1284 the great battle of Meloria took place. Here seventy-two Pisan galleys engaged eighty-eight Genoese, and half the Pisan fleet was destroyed. The chroniclers speak of 5000 killed and 11,000 prisoners; and, although these figures must be exaggerated, so great was the number of captives taken by the Genoese as to give rise to the saying—"To see Pisa, you must now go to Genoa." This defeat crushed the power of Pisa. She lost her dominion over the sea, and the Tuscan Guelphs again joined in attacking her by land. Count Ugolino had taken part in the battle of Meloria and was accused of treachery. At the height of his country's disasters he sought to confirm his own power by making terms with the Florentines, by yielding certain castles to Lucca, and by neglecting to conclude negotiations with the Genoese for the release of the prisoners, lest these should all prove more or less hostile to himself. This excited a storm of opposition against him. The archbishop Ruggieri, having put himself at the head of the nobility, was elected podestà by the Lanfranchi, Simondi and Gualandi, and a section of the popular party. The city was plunged into civil war. The great bell of the commune was rung together with the adorers of the archbishop; the bell of the people summoned the partisans of the count. After a day's fighting (July 1, 1288) the count, his two sons and his two grandsons were captured in the palazzo del popolo ([and town hall]), and cast into a tower belonging to the Gualandi and known as the "Tower of the Seven Streets." Here they were all left to die of hunger. Their tragic end was afterwards immortalized in the Divina commedia. The sympathies of Dante Alighieri, the Florentine patriot and foe of Rome, were naturally in favour of the victims of an aristocratic pretatebe, opposed to all reconciliation with Florence.

The Florentines were now allied with Lucca and Genoa, and a few of their vessels succeeded in forcing an entry into the Pisan port, blocked it with sunken boats, and seized its towers. Their own internal divisions, and the continuance of the campaign, but not before they had concluded an advantageous peace. They and all the members of the Guelph league were freed from all imposts in Pisa and its port. In addition to these privileges the Genoese also held Corsica and part of Sardinia; and throughout the island of Elba they were exempted from every tax. They likewise received a ransom of 160,000 lire for their Pisan prisoners. These were no longer numerous, many having succumbed to the hardships and sufferings of all kinds to which they had been exposed.

In 1312 the arrival of the emperor Henry VII. gladdened the hearts of the Pisans, but his sudden death in 1313 again overthrew their hopes. He was interred at Pisa, and Ugucinno della Faggiuola remained as imperial lieutenant, was elected podestà and captain of the people, and thus became virtual lord of the city. As a Ghibelline chief of valour and renown he was able to restore the military prestige of the Pisans, who under his command captured Lucca and defeated the Florentines at Montecatini on the 29th of August 1315. So tyrannical, however, was his rule that in 1316 he was expelled by the popular fury. But Pisa's freedom was for ever lost. He was succeeded by other lords or tyrants, of whom the most renowned was Castruccio Castracane, a political and military adventurer of much the same stamp as Ugucinno himself. With the help of Louis the Bavarian, Castruccio became lord of Lucca and Pisa, and was victorious over the Florentines; but his premature death in 1328 again left the city a prey to the conflicts of opposing factions. New lords, or petty tyrants, rose to power in turn during this period of civil discord, but the military valour of the Pisans was not yet extinguished. By sea they were almost impotent—Corsica and Sardinia were lost to them for ever; but they were still formidable by land. In 1341 they besieged Lucca in order to prevent the entry of the Florentines, to whom the city had been sold for 250,000 florins by the powerful Mastino della Scala. Aided by their Milanese, Mantuan and Paduan allies, they gave battle to their rivals, put them to rout at Altopascio (Oct. 2), and then again excluded them from their port. Thereupon the Florentines obtained Porto Talamone from Siena and established a navy of their own. By this means they were enabled to capture the island of Giglio, and, attacking the Pisan harbour, carried off its chains, bore them triumphantly to Florence, and surprised them in front of the baptistery, where they remained until 1348. Then, in pledge of the brotherhood of all Italian cities, they were given back to Pisa, and placed in the Campo Santo.

The war was now carried on by the free companies with varying fortune, but always more or less to the hurt of the Pisans. In 1369 Lucca was taken from them by the emperor Charles IV.; and afterwards Giovan Galeazzo Visconti, known as the count of Virdi, determined to forward his ambitious designs upon the whole of Italy by wresting Pisa from the Gambacorti. For at this time the conflicts of the Raspanti faction, headed by the Ghersadesca, with the Bergolini led by the Gambacorti, had left the latter family masters of the city. At Visconti's instigation Piero Gambacorti, the ruler of the moment, was treacherously assassinated by Jacopo d'Appiano, who succeeded him as tyrant of Pisa, and bequeathed the state to his son Gherardo. The latter, a man of inferior ability and daring, sold Pisa to the count of Virtu, receiving in exchange 200,000 florins, Piombino, and the islands of Elba, Pianosa and Monte Cristo. Thus in 1390 Visconti took possession of Pisa, and left it to his natural son Gabriele Maria Visconti, who was afterwards expelled from its gates. But even during this century of disaster the Pisans continued to cherish not only commerce, but also the fine arts. In the year 1378 they had entrusted the erection of their fine Campo Santo to Niccola and Giovanni Pisano, by whom the architectural part of it was completed towards the end of the century. In the following year the first artists of Italy were engaged in its decoration, and the celebrated frescoes attributed to Orcagna (q.v.) were painted on its walls. Others were afterwards supplied by Benozzo Gozzoli and men of lesser note, and the labour of ornamentation was only discontinued in 1404.

Meanwhile, in 1406, the Florentines made another attack upon Pisa, besieging it simultaneously by sea and land. Owing to the starving condition of its defenders, and aided by the treachery of Giovanni Gambacorti, they entered the city in triumph on the 9th of October, and sought to "crush every germ of rebellion and drive out its citizens by measures of the utmost harshness and cruelty." Such were the orders sent by the Ten of War to the representatives of the Florentine government in Pisa, and such was then the established policy of every Italian state. Consequently for a long time there was a continual stream of emigration from Pisa. The Medici pursued a humane course.

In 1472 Lorenzo the Magnificent tried to restore the ancient renown of the Pisan university. To that end he filled it with celebrated scholars, and, leaving only a few chairs of letters and philosophy in Florence, compelled the Florentines to resort to Pisa for the prosecution of their studies. But nothing could now allay the inextinguishable hatred of the conquered people. When Charles VIII. made his descent into Italy in 1494, and came to Sarzana on his way to Tuscany, he was welcomed by the Pisans with the greatest demonstrations of joy. And, although that monarch was ostensibly the friend of Florence, they did not
hesitate, even in his presence, to assert their own independence, and, casting the Florentine ensign, the Marzocco, into the Arno, made instant preparations for war. Between 1499 and 1505 they heroically withstood three sieges and repulsed three attacking armies. But their adversaries always returned to the assault, and, what was worse, yearly laid waste their territories and destroyed all or part of Soderini's grand viziers of Florence, and Machiavelli, the secretary of the Ten, urged on the war. In 1509 Florence encamped her forces on three sides of the distressed city, which at last, reduced to extremity by famine, was compelled to surrender on the 8th of June 1509. Thenceforth the Florentines remained lords of Pisa. But now, mainly owing to the efforts of Soderini and Machiavelli, the conquerors showed great magnanimity. They brought with them large stores of provisions, which were freely distributed to all; they tried to succour the suffering populace in every way, and gave other assistance to the wealthier classes. Nevertheless, emigration continued even on a larger scale than in 1406, and the real history of Pisa may be said to have ended. In Naples, in Palermo, in all parts of Italy, Switzerland and the south of France, we still find the names of Pisan families who quitted their beloved home at that time, and the Florentine immemorially built a new citadel, and this was a great bitterness to the Pisans. The Medici, however, remained well disposed towards the city. Leo X. was an active patron of the university, but it again declined after his death. The grand duke Cosimo I., a genuine statesman, not only restored the university, but instituted the "ufficio dei fiorini," or drainage office for the reclamation of marsh lands, and founded the knighthood of St Stephen. This order played a noble part in the protection of Tuscan commerce, by fighting the Barbary pirates and establishing the prestige of the grand-ducal navy (see MEDICI). Under the succeeding Medici, Pisa's fortunes steadily declined. Ferdinand I. initiated a few public works there, and above all restored the cathedral, which had been partly destroyed by fire in 1395. These dreary times, however, are brightened by one glorious name—that of Galileo Galilei.

The population of Pisa within the walls had been reduced in 1532 to 8,574 souls, and by 1745 it had only risen to the number of 12,606. Under the house of Lorraine, or more correctly during the reign of that enlightened reformer the grand duke Peter Leopold (1765-1790), Pisa shared in the general prosperity of Tuscany, and its population constantly increased. By 1840 it contained 21,670 souls, exclusive of the suburbs and outlying districts.

AUTHORITIES.—Paolo Tronci, Annali di Pisa, edited by E. V. Montazio (2 vols., Lucca, 1842-1843), which comes down to 1840; Ranieri Grassi, Pisa e la sua odicina (Pisa, 1851), a useful topographical guide; Roncefoni, "Istorie Pisane," in the Archivio storico italiano, vol. vi., pt. 1; "Cronache Pisane," in the Archivio, vol. vi. pt. 2; for the early constitution of the city, see G. Volpe's Studi sulle istituzioni, comunali di Pisa (Pisa, 1902), and for the laws, F. Bonafini's Statuti inediti della città di Pisa (3 vols., Florence, 1851, &c.). The maritime and commercial history of the republic is dealt with in A. For Dante's connexion with Pisa, see Dante e i Pisani, by Giovanni Sforza (Pisa, 1873). Among the more recent historical guides to Pisa of a popular character is The Story of Pisa and Lucca, by Jane K. Stoddart and Nellie Erichsen; in Dent's "Medieval Towns" (London, 1907), and T. B. Supino's Pisa, in the "Italia artistica Series." (P. V.)

PISA, COUNCIL OF (1409). The great schism of the west had already lasted thirty years, and the efforts which had been made to restore unity within the Church by the simultaneous resignation of the two rival pontiffs had been in vain, when in the spring of 1408, the state of affairs being desperate, the idea arose of assembling a council to effect a union without the co-operation of the popes. The initiative came from those cardinals who had one after the other seceded either from Gregory XII. or Benedict XIII. They were forestalled by the popes, who each summoned a council, the former to Cividale (in Friuli), the latter to Perpignan, so the dissident cardinals sent out antedated letters inviting Christendom to assemble at Pisa on the 25th of March 1409. Their appeal met with a response in a great part of Italy, France, Navarre, Portugal and England, and in Germany in the Palatinate subject to Wi, whose emperor, the Romans, the Electors of Cologne and Mainz, the margrave of Brandenburg, &c. For a time the number of the fathers exceeded five hundred.

The day after the opening of the council, proceedings were started against the two popes, who, it was agreed, were to be eliminated. An act of accusation, containing in 37 articles the chief complaints against them, was read out to the people; not only their policy, but their orthodoxy was attacked, and there was even an insinuation of sorcery. The reason is, that in order to depose them with some show of legality, it was necessary, as a preliminary, to convict them of heresy, and it began to be seen that their tenacity of power, and the ruses by which they evaded the necessity of abdicating, however harmful might be their consequences, did not in themselves constitute a clearly-defined heresy. On the 5th of June 1409 was read the definitive sentence: they were hereafter, and for ever, separated from the Church, Pedro de Luna (Benedict XIII.) and Angelo Corrario (Gregory XII.) were ipso facto deposed from any office; they must not be obeyed, nor assisted, nor harboured. In the course of the rejoicings which followed this sentence among the populace of Pisa, occurred the somewhat scandalous event of the burning of two images crowned with parchment mitres, representing Gregory XII. and Benedict XIII. It was in vain that the ambassadors of Benedict XIII. presented themselves at Pisa. The crowd greeted their arrival with mockery and derision, and being treated as the envys of heretics they escaped without having obtained a hearing.

In order to complete their task the cardinals present at Pisa, authorized by delegation of the council, shut themselves up in conclave, and elected one of their number, Peter Philargies, cardinal of Milan, as the new pope, who assumed the name of Alexander V. They had hoped to save the Church, but unfortunately the result of their efforts, generous as they were, was that the schism increased in bitterness, and that instead of the unity for which the Church craved, three popes continued to flourish. Both the deposed pontiffs protested against the legality of the council of Pisa; each had numerous partisans, and the thesis, constructed rather to meet the exigencies of the case, which attributed to a synod assembled by the cardinals the right of constituting itself judge of a sovereign pontiff, was far from being established.

Originally the council of Pisa was to have occupied itself not only with effecting the union, but also with the reform of the Church. As a matter of fact, it confined itself to expressing certain desiderata in a "libellus supplicatorius" which it submitted to the new pope. Alexander V. only partially acceded to these demands, many of which constituted serious encroachments on the prerogative of the Holy See; he then declared the work of reform suspended, and dissolved the council (August 7, 1409).

PIŠACA LANGUAGES, the name which has been given to a family of languages spoken immediately to the south of the Hindu Kush, and north of the frontier of British India. The family includes the group of Kafir languages spoken in Kafirstan, Khwar, spoken in the Chital country, and the group of Shina languages, which includes the Shina of Gilgit, Kohistan, spoken in the Kohistsans of the Indus and Swat rivers, and Kashmiri. Of all these Kashmiri is the only one which has received any literary cultivation, and of which the number of speakers is known. The Pišäca languages are Aryan by origin, but are neither Iranian nor Indo-Aryan. (See Indo-Aryan Languages and Kashmiri.) (G. A. Gr.)
PISACANE—PISANO, A.

PISACANE, CARLO, duke of San Giovanni (1818–1877), Italian revolutionary, was born at Naples, and entered the Neapolitan army in 1839; but having become imbued with Mazzinian ideas he emigrated in 1847, and after a short stay in England and France served in the French army in Algeria. The revolution of 1848 recalled him to Italy; he played a part in the brief but glorious history of the Roman Republic, and was the life and soul of the war commission in the defence of the city. After its capture by the French he again went into exile, first to London and then to Genoa, maintaining himself by teaching. He regarded the rule of the house of Savoy as no better than that of Austria. When Mazzini, undeterred by the failure of the abortive Milan rising on the 6th of February 1853, determined to organize an expedition to provoke a rising in the Neapolitan kingdom, Pisacane offered himself for the task, and sailed from Genoa with a few followers (including Giovanni Nicotera) on board the “Caglioni” on the 27th of June 1857. They landed on the island of Ponza, where the guards were overpowered and some hundreds of prisoners liberated, and on the 28th arrived at Sapri in Calabria and attempted to reach the Cilento. But hardly any assistance from the inhabitants was forthcoming, and the French troops were quickly overpowered, Pisacane himself being killed.

See P. M. Bilotti, La Spedizione di Sapri (Salerno, 1907).

PISANI, VETTOR (d. 1380), Venetian admiral, was in command of the Venetian fleet in 1378 during the war against the Genoese, whom he defeated off Capo d’Anzio; subsequently he recaptured Cattaro, Sebenico and Arbe, which had been seized by the Hungarians, the allies of the Genoese. But the Genoese fleet completely defeated Pisani at Pola in May 1379, and on his return to Venice he was thrown into prison. The enemy now pressed home their victory, and besieged and captured Chioggia, whereby Venice itself was in danger. The people thereupon demanded the liberation of Pisani, in whose skill they had the fullest confidence. The government gave way and appointed the aged commander admiral of the fleet once more. Through his able strategy and daring he recaptured Chioggia, defeated the Genoese and threatened Genoa itself until that republic agreed to peace terms. Pisani died in 1380 while on his way to Manfredonia with a squadron to ship provisions.

PISANO, ANDREA, also known as ANDREA DA PONTAVERA (c. 1270–1348), Italian sculptor, was born about 1270, and first learned the trade of a goldsmith. He became a pupil of Giovanni de la paix (1412–1413), but after the disasters of the campaign of Agincourt she retired to a convent. We have no more of her work until 1420, when she broke her silence to write a song in honour of Joan of Arc. Of the circumstances of her death nothing is known but it probably took place about this time.

Her Cité des dames contains many interesting contemporary portraits, and her Livre des trois vertus contains details of domestic life in the France of the early 15th century not supplied by more formal historians.

Her poems were edited by Maurice Roy for the Société des anciens Textes français (1886, &c.), and her Livre du chemin du long étude, by Puschel (Berlin, 1887). There are monographs by Raimond Thomassy (Paris, 1838); E. M. D. Robineau (Saint-Omer, 1882); and Friedrich Koch (Goslar, 1885). It is possible that Jean Castel, who was chronicler of France under Louis XI., was Christine’s grandson. Hoechev wrote her Épitre au dieu d’amour, in his Letter of Capid (Chaucerian and other Pieces, ed. W. W. Skeat, 1897). A translation of her Épitre d’Othée was made (c. 1440) by Stephen Scrope for his stepfather, Sir John Fastolf, and is preserved in a MS. at Longleat. This was edited (1903) for the Roxburghe Club by W. C. F. Warner as The Epistle of Otho to Hector, or the Boe of Knyghtode. The Moral Proverbs of Christyne de Pise, translated by Earl Rivers, was printed in 1478 by Caxton, who himself translated, by order of Henry VII., her Livre des faits d’armes, et de chevalerie, a treatise on the art of war, based chiefly on Vegetius. Her Cité des dames was translated by Brian Anslay (London, 1521).

PISANO, A., is a bronze Door of the Baptistery at Florence, by Andrea Pisano. Pisano about 1300, and worked with him on the sculpture for S. Maria della Spina at Pisa and elsewhere. But it is at Florence

Part of the first Bronze Door of the Baptistery at Florence, by Andrea Pisano.
that his chief works were executed, and the formation of his mature style was due rather to Giotto than to his earlier masters. Of the three world-famed bronze doors of the Florentine baptistry, the earliest one—that on the south side—was the work of Andrea; he spent many years on it; and it was finally set up in 1336. It consists of a number of small quatrefoil panels—the lower eight containing single figures of the Virtues, and the rest scenes from the life of the Baptist. Andrea Pisano, while living in Florence, also produced many important works of marble sculpture, all of which show strongly Giotto’s influence. In some cases probably they were actually designed by that artist, as, for instance, the double band of beautiful panel-reliefs which Andrea executed for the great campanile. The subjects of these are the Four Great Prophets, the Seven Virtues, the Seven Sacraments, the Seven Works of Mercy and the Seven Planets. The duomo contains the chief of Andrea’s other Florentine works in marble. In 1347 he was appointed architect to the duomo of Orvieto, which had already been designed and begun by Lorenzo Maitani. The exact date of his death is not known, but it must have been shortly before the year 1349.

Andrea Pisano had two sons, Nino and Tommaso—both, especially the former, sculptors of considerable ability. Nino was very successful in his statues of the Madonna and Child, which are full of human feeling and soft loveliness—a perfect embodiment of the Catholic ideal of the Divine Mother. Andrea’s chief pupil was Andrea di Cione, better known as Orcagna (q.v.). Balduccio di Pisa, another, and in one branch (that of sculpture) equally gifted pupil, executed the wonderful shrine of St. Eustorgio at Milan—a most magnificent mass of sculptured figures and reliefs.

PISANO, GIOVANNI (c. 1250-1330), Italian architect and sculptor, was the son of Niccola Pisano. Together with Arnolfo del Cambio and other pupils, he developed and extended into other parts of Italy the renaissance of sculpture which in the main was due to his father’s talent. After he had spent the first part of his life at home as a pupil and fellow worker of church of S. Domenico in 1304, but little of the original structure remains. The north transept, however, still contains his beautiful tomb of Benedict XI., with a sleeping figure of the pope, guarded by angels who draw aside the curtain. One of Giovanni’s most beautiful architectural works was the little chapel of S. Maria della Spina (now rebuilt, “restored”), on the banks of the Arno in Pisa; the actual execution of this chapel, and the sculpture with which it is adorned, was mostly the work of his pupils. The influence of his father Niccola is seen strongly in all Giovanni’s works, but especially in the pulpit of S. Andrea at Pistoia, executed about 1300. Another pulpit, designed on the same lines, was made by him for the nave of Pisa Cathedral between 1310 and 1311. The last part of Giovanni’s life was spent at Prato, near Florence, where with many pupils he worked at the cathedral till his death about 1330.

See M. Sauerland, Über die Bildwerke des Giovanni Pisano, &c. (1904); A. Brach, Niccola und Giovanni Pisano und die Plastik des XIV. Jahrhunderts in Siena (1904).

PISANO, NICCOLA (c. 1206-1278), Italian sculptor and architect. Though he called himself Pisano, from Pisa, where most of his life was spent, he was not a Pisan by birth. There are two distinct accounts of his parentage, both derived mainly from existing documents. According to one of these he is said to have been the son of “Petrus, a notary of Siena;” but this statement is very doubtful, especially as the word “Siena” (c. de Senis) appears to be a conjectural addition. Another opinion, which is among the Sienese accepted by some writers, is that he was the son of “Petrus de Apulia.” Most modern writers accept the latter statement, and believe that he not only was a native of the province of Apulia in southern Italy, but also that he gained there his early instruction in the arts of sculpture and architecture. Those, on the other hand, who, with most of the older writers, prefer to accept the theory of Niccola’s origin being Tuscan, suppose that he was a native of a small town called Apulia near Lucca.

Except through his works, but little is known of the history of Niccola’s life. As early as 1221 he is said to have been summoned to Naples by Frederick II., to do work in the new Castel del’Uovo. This fact supports the theory of his southern origin, though not perhaps very strongly, as, some years before, the Pisan Bonannus had been chosen by the Norman king as the sculptor to cast one of the bronze doors for Monreale Cathedral, where it still exists. The earliest existing piece of sculpture which can be attributed to Niccola is a beautiful relief of the Deposition from the Cross in the tympanum of the arch of a side door of the Lateran church at Lable; it is one of his earliest known works, small in composition and delicate finish of execution. The date is about 1237. In 1260, as an incised inscription records, he finished the marble pulpit for the Pisan baptistery; this is on the whole the finest of his works.

It is a high octagon, on semicircular arches, with trefoil cusps, supported by nine marble columns, three of which rest on white marble lions. In design it presents that curious combination of Gothic forms with classical details which is one of the characteristic features of the medieval architecture of northern Italy; though much enriched with sculpture both in relief and in the round, the general lines of the design are not sacrificed to this, but the sculpture is kept subordinate to the whole. In this respect it is superior to the more magnificent pulpit at Siena, one of Niccola’s later works, which is greatly overloaded with repose and purity of outline, owing to its being overloaded with reliefs and statuettes. Five of the sides of the main octagon have panels with subjects—the Nativity, the Adoration of the Magi, the Presentation in the Temple, the Flight into Egypt and the Doimon. These are all, especially the first three, works of the highest beauty, and a wonderful advance on anything of the sort that had been produced by Niccola’s predecessors. The drapery is gracefully arranged in broad simple folds; the heads are full of the most noble dignity; and the weight yet stately beauty of the Madonna could hardly be surpassed. The panel with the Adoration of the Magi is perhaps the one in which Niccola’s study of the antique is most apparent (see figure). The veiled and diademed figure of the Virgin Mother, seated on a throne, recalls the Roman Juno; the head of Joseph might be that of Vulcan; while the youthful beauty of an Apollo and the mature dignity of a Jupiter are suggested by the standing

\[1\] The date on the door, 1330, refers to the original wax model.

\[2\] See Schultz, Denkmäler der Kunst in Unter-Italien, vii. 5.
and kneeling figures of the Magi. Certain figures in others of the panels are no less deeply imbued with classical feeling.

The next important work of Niccola in date is the Arca di San Domenico, in the church at Bologna consecrated to that saint, who died in 1221. Only the main part, the actual sarcophagus covered with sculptured reliefs of St Dominic's life, is the work of Niccola and his pupils. The sculptured base and curved roof with its fanciful ornaments are later additions. This "Arca"

The Adoration of the Magi, one of the panels in the pulpit of the Pisan Baptistery, by Niccola Pisano.

was made when St Dominic was canonized, and his bones translated; it was finished in 1267, not by Niccola himself, but by his pupils. The most magnificent, though not the most beautiful, of Niccola's works is the great pulpit in Siena cathedral (1268). It is much larger than that at Pisa, though somewhat similar in general design, being an octagon on cusped arches and columns. Its stairs, and a large landing at the top, with carved balusters and panels, rich with semi-classical foliage, are an addition of about 1590. The pulpit itself is much overloaded with sculpture, and each relief is far too crowded with figures. An attempt to gain magnificence of effect has destroyed the dignified simplicity for which the earlier pulpit is so remarkable.

Niccola's last great work of sculpture was the fountain in the piazza opposite the west end of the cathedral at Perugia. This is a series of basins rising one above another, each with sculptured bas-reliefs; it was begun in 1274, and completed, except the topmost basin, which is of bronze, by Niccola's son and pupil Giovanni.

Niccola Pisano was not only pre-eminent as a sculptor, but was also the greatest Italian architect of his century; he designed a number of very important buildings, though not all which are attributed to him by Vasari. Among those now existing the chief are the main part of the cathedral at Pistoia, the church and convent of Sta Margherita at Cortona, and Sta Trinità at Florence. The church of Sant' Antonio at Padua has also been attributed to him, but without reason. Unfortunately his architectural works have in most cases been much altered and modernized. Niccola was also a skilled engineer, and was compelled by the Florentines to destroy the great tower, called the Gualdomo, which overshadowed the baptistery at Florence, and had for long been the scene of violent conflicts between the Guelphs and Ghibellines. He managed skilfully so that it should fall without injuring the baptistery. Niccola Pisano died at Pisa in the year 1278, leaving his son Giovanni a worthy successor to his great talents both as an architect and sculptor.

Though his importance as a reviver of the old traditions of beauty in art has been to some extent exaggerated by Vasari, yet it is probable that Niccola, more than any other one man, was the means of starting that "new birth" of the plastic arts which, in the years following his death, was so fertile in countless works of the most unrivalled beauty. Both Niccola and his son had many pupils of great artistic power, and these carried the influence of the Pisani throughout Tuscany and northern Italy, so that the whole art of the succeeding generations may be said to have owed the greater part of its rapid development to this one family.

See SCULPTURE, and general histories of Italian art; Symonds, Renaissance in Italy; A. Brach, Nicola und Giovanni Pisano und die Plastik des XIV. Jahrhunderts in Siena (Strassburg, 1904).

PISANO, VITTOR (c. 1380–1465), commonly called PISANNOLO, Italian medalist, was a native of San Vignolo sul Lago in the territory of Verona. Specimens of his work as a painter are still extant in Rome, Venice, Verona and Pistoia, and entitle him to a place of some distinction in the history of that art. The National Gallery in London possesses a very fine specimen of Pisanello's work—a panel painted with miniature-like delicacy. During the latter portion of his life he lived in Rome, where he enjoyed great repute.

PISANUM (mod. Pesaro, q.v.), an ancient town of Umbria on the Via Flaminia, 26 m. from Ariminum and 8 from Fanum Fortunae. A Roman colony was founded here in the territory of the Galli Senones in 184 B.C. at the mouth of the river Pisanus (mod. Foglia; the sea has since then receded about half a mile). Whether it took the place of an earlier town or not, is not known: an important Gaulish cemetery has been discovered near the village of Novilara between Pisaurum and Fanum, but to which of these centres (if either) it belonged is uncertain (E. Brizio in Monumenti dei Lincei [1893], v. 85 seq.). In 174 B.C. we hear that the censors built a temple of Jupiter here and paved a road. The town was afterwards called Cluentium and Cluentius, a powerful citizen, is said to have opposed Servius Tullius when he defended Cluentius in a still extant speech, as a native of Pisaurum. Catullus refers to the town as decadent or unhealthy, but this may be merely malicious, and does not seem to be borne out by facts: for it is not infrequently mentioned by classical authors. It was occupied by Caesar in 49 B.C., and was made a colony under the second triumvirate. Hence it bears the name Colonia Julia Felix. We hear little of it under the empire. It was destroyed by the Goths in 539, and restored by Belisarius in 545. From the inscriptions, nearly 200 in number, an idea of the importance of the town may be gained. Among them are a group of cippi found on the site of a sacred grove of the matrons of Pisaurum, bearing dedications to various deities, and belonging probably to the date of the foundation of the colony. There are some remains of the town walls, and an ancient bridge over the Foglia. It was, like Ariminum, a considerable place for the manufacture of bricks and pottery, though the factories cannot always be precisely localized.

PISCES (the fishes), in astronomy, the twelfth sign of the zodiac (q.v.), represented by two fishes tied together by their tails and denoted by the symbol ♒. It is also a constellation, mentioned by Eudoxus (4th century B.C.) and Aratus (3rd century B.C.); and catalogued by Ptolemy (38 stars), Tycho Brahe (36) and Hevelius (39). In Greek legend Aphrodite and Eros, while on the banks of the Euphrates, were surprised by Typhon, and sought safety by jumping into the water, where they were changed into two fishes. This fable, however, as in many other similar cases, is probably nothing more than an adaptation of an older Egyptian tale. a Piscium, a fine double star of magnitude 3 and 4; 35 Piscium, another double star, the components being a white star of the 6th magnitude and a purplish star of the 8th magnitude.

Pisciaustralis, the southern fish, is a constellation of the southern hemisphere, mentioned by Eudoxus and Aratus, and catalogued by Ptolemy, who described 18 stars. The most important star is a Pisciaustralis or Fomalhaut, a star of the first magnitude. Piscis australis, the flying fish, is a new constellation introduced by John Bayer in 1603.

PISCICULTURE (from Lat. piscis, fish). The species of fish which can be kept successfully in captivity throughout their whole life, and denoted by the symbol ♒. It is also a constellation, mentioned by Eudoxus (4th century B.C.) and Aratus (3rd century B.C.); and catalogued by Ptolemy, who described 18 stars. The most important star is a Pisciaustralis or Fomalhaut, a star of the first magnitude. Piscis australis, the flying fish, is a new constellation introduced by John Bayer in 1603.

PISCICULTURE (from Lat. piscis, fish). The species of fish which can be kept successfully in captivity throughout their whole life, and denoted by the symbol ♒. PISCICULTURE

Fish-rearing.—Of the first type of pisciculture there are few examples of commercial importance. The pond-culture of carp is an important industry in China and Germany, and has been introduced with some success in the United States, but in England it has long fallen out of use, and is not likely to be revived so long as fresh fish can be obtained and distributed so readily as is now the case. Other examples are to be found in the cultivation of the lagoons of the Adriatic, and of the salt-marshes of various parts of France. Here, as in ancient Greece and Rome, it is the practice to admit young fish from the sea by sluices, into artificial enclosures or "viviers," and to keep them there until they are large enough to be used. An interesting modification of this method of cultivation has been introduced into Denmark. The entrances to the inner lagoons of the Limfjord are naturally blocked against the immigration of flatfish by dense growths of sea-grass (Zostera), although the outer lagoons are annually invaded by large numbers of small plaice from the North Sea. The fishermen of the district consequently combined to defray the expenses of transplanting large numbers of small plaice from the outer lagoons to the inner lagoons, where they were found to thrive far better than in their natural habitat. The explanation has been shown by Dr Petersen to be due to the abundance of food, coupled with the lack of overcrowding of the small fish. This transplantation of plaice in Denmark has been annually repeated for several years with the most successful results, and a suitable subvention to the cost is now an annual charge upon the government funds.

As a result of the international North Sea fishery investigations, it has been proposed to extend the same principle for the development of the deep sea fishery in the neighbourhoud of the Dogger Bank. Experiments with larvae carried out by the Admiralty and by the Marine Biological Association, showed that small plaice transplanted to the Dogger Bank in spring grew three times as rapidly as those on the inshore grounds, and the same result, with insignificant variations, has been obtained by similar experiments in each of the following years. In this case the deep water round the Dogger Bank acts as a barrier to the emigration of the small plaice from the shores. It has consequently been proposed that the small plaice should be transplanted in millions to the Bank by well vessels every spring. It is claimed, as a further result of the experiments, that from May to October the young fish would be practically free on the shallow part of the Bank from the risk of premature capture by trawlers, and that the increased value of the fish, consequent upon their greater normal growth-rate, would greatly exceed the cost of transplantation.

The methods of oyster- and mussel-culture are similar in principle to those just described. A breeding stock is maintained to supply the young shells; these are grown in the water or in shallow tanks, and flourish quite sufficiently, is then transplanted to the most suitable feeding-grounds, care being taken to avoid the local over-crowding which is so commonly observed among shell-fish under natural conditions.

Fish-hatchery.—The second, and more familiar, type of pisciculture is that known as fish-hatchery, with which must be associated the various methods of artificial propagation.

The fertilization of the spawn is very easily effected. The eggs are collected either by "stripping" them from the mature adult immediately after capture, or by keeping the adults alive until they are ready to spawn, and then stripping them or by keeping them in reservoirs of sea-water and allowing them to spawn of their own accord. In the two former cases a little milt is allowed to fall from a male fish into a vessel containing a small quantity of water—fresh or salt as required—and the eggs are pressed from the female fish into the same vessel. In fresh-water culture the eggs thus fertilized may be at once distributed to the waters to be stocked, or they may be kept in special receptacles provided with a suitable stream of water until the fry are hatched, and then distributed, or again they may be reared in the hatchery for several months until the fry are active and hardy.

The hatching of eggs, whether of fresh-water or salt-water fishes, presents no serious difficulties, if suitable apparatus is employed; but the rearing of fry to an advanced stage, without serious losses, is less easy, and in the case of sea-fishes with pelagic eggs, the larvae of which are exceedingly small and tender, is still an unsolved problem, although recent work, carried out at the Plymouth laboratory of the Marine Biological Association, is at least promising. It has been found possible to grow pure cultures of various diatoms, and by feeding these to delicate larvae kept in sterilized sea-water, great successes have been attained. In fresh-water culture little advantage, if any, has been found to result from artificial hatching, unless this is followed by a successful period of rearing. Thus the Howetown Fishery Company recommend their customers to stock their streams either with unhatched ova or with three-month-old fry. Their experience is "that there is no half-way house between ova sown in reds and three-month-old fry. Younger fry may do, but only where ova would do as well, and at half the cost." In marine hatcheries, on the other hand, it is the invariable practice to hatch the eggs, although the fry have to be put into the sea at the most critical period of their lives. If it is a risky matter to plant out the robust young fry of trout under an age of three months, it would seem to be an infinitely more speculative proceeding to plant out the delicate week-old larvae of sea-fishes in an environment with enemies or predators to bole them.

Objects and Utility of Fish-hatcheries.—The earlier advocates of artificial propagation and fish-hatching seem to have been under the impression that the thousands of fry resulting from a single act of artificial propagation meant a corresponding increase in the numbers of edible fish when once they had been deposited in suitable waters; and also that artificial fertilization ensured a greater proportion of fertilized eggs than the natural process. For the second of these propositions there is no evidence, while the first proposition is now everywhere discredited. It is recognized that the great fertility of fishes is nature's provision to meet a high mortality—greater in sea-fishes with minute pelagic eggs than in fresh-water fishes with larger-yolked eggs, partly because of the greater risks of marine pelagic life, and partly because of the greater delicacy of marine larvae at the time of hatching. Artificially propagated eggs and fry after planting must submit to the same mortality as the other eggs and fry around them. Consequently it is useless to plant out eggs or fry unless in numbers sufficiently great to appreciably increase the stock of eggs and fry already existing.

It is this, combined always with the suitability of the external conditions, which accounts for the success of the best known experiments of American pisciculturists. The artificially propagated eggs of the shad from the eastern rivers of the United States were planted in those of California and the Mississippi, where the species did not naturally occur. The conditions were suitable, and the species became at once acclimatized. Similarly reservoirs and streams can be stocked with various kinds of fish not previously present. But in the case of indigenous species the breeding stock must be very seriously reduced before the addition of the eggs or fry of a few score or hundreds of fish can appreciably increase the local stock.

In the case of sea-fishes it is becoming increasingly recognized that the millions of cod fry which are annually turned out of the American, Newfoundland and Norwegian hatcheries are but an insignificant fraction of the billions of fry which are naturally produced. A single female cod liberates, according to its size, from one to five million eggs in a single season. Yet the annual output of fry from each of these hatcheries rarely exceeds 200 millions, i.e. the natural product of a few hundred cod at most. In Britain marine hatcheries have been established by the Fishery Board for Scotland in the bay of Nigg, near Aberdeen, by the Lancashire Sea Fisheries Committee at Peel, and by the government of the Isle of Man at Port Erin. These establishments have been principally devoted to the hatching of the eggs of plaice. But again the maximum output of fry from any one of these establishments has not exceeded 40 millions in any single year. As a single female plaice produces about 200,000 eggs per annum, this output does not exceed the natural produce of a few hundred fish. Under these circumstances the probable utility of the operations could be...
admitted only if the fry were sedentary and could be planted in suitable localities where young fish were naturally scarce. But the fry drift with the currents as helplessly as the eggs, and the a priori objections to the utility of the operations have in no case been met by evidence of tangible results. The plaice fry hatched in the Scottish establishment have been distributed for many years in the waters of Loch Fyne. Yet in this area, according to the investigations of Mr Williamson (Report of the Scottish Fishery Board for 1898), nearly 500 millions of plaice eggs are naturally produced in one spawning season. Evidence is still lacking as to whether the 20 to 30 million fry annually added from the hatchery have appreciably increased the quantities of young plaice on the surrounding shores. Supposing this could be established, the question would still remain whether the same result could not be obtained at far less expense by dispensing with the hatching operations and distributing the eggs directly after fertilization.

In the United States the utility of the cod-hatching operations has been constantly asserted by representatives of the Bureau of Fisheries, but practically the only evidence adduced is the occasional appearance of unusual numbers of cod in the neighbourhood. It has not been established that the fluctuations in the local cod fisheries bear any fixed relation to the extent of the hatching operations, while the earlier reports of the Commissioners of Fisheries contain evidence that similar fluctuations occurred before the hatching of “fish commission cod” had begun.

The situation may be summed up in the words of Mr Fryer, H.M. Superintending Inspector of Fisheries, who critically examined the evidence bearing upon the operations of the Newfoundland Hatchery at Dildo (Reports x.-xii. of the Inspectors of Sea Fisheries, E. & W.): “Where the establishment of a hatchery, even on the smallest scale, is followed by an increased take of fish, there is a tendency to connect the two as cause and effect on insufficient evidence, and without any regard to the many conditions which have always led to fluctuations in the case of any particular kind of fish.”

The most exact investigations bearing upon this problem are those which have been recently undertaken in Norway in connexion with the cod-hatching operations at Arendal under Captain Dannevig. Four fjords were selected in the south coast of Norway in proximity to the hatchery, and the usual number of fry (10-30 millions) were planted in the spring in alternate fjords, leaving the intermediate fjords unsupplied. The relative number of young cod in the various fjords was then carefully investigated throughout the succeeding summer and autumn months. It was found that there was no relation between the abundance of young fish and the presence or absence of “artificial” fry. In 1904, 33 million fry were planted in Sondelefjord and young fish were exceptionally abundant in the following autumn (three times as abundant as in 1903 when no fry were planted). But their abundance was equally striking in other fjords in which no fry had been added, and in 1905 all the fjords were deficient in young cod whether they had been planted with fry or not, the hatchery being closed.

For a summary of these investigations see papers on “Artificial Fish-hatching in Norway” by Captain Dannevig and Mr Dahl, in the Report of the Lancashire Sea Fisheries Laboratory for 1906 (Liverpool, 1907).

It would thus seem clear that the attempts hitherto made to increase the supply of sea-fish by artificial hatching have been unsuccessful. The experience gained has doubtless not been wasted, but the direction to be taken by future work is plain. The energy and money devoted to hatching operations should be diverted to the serious attempt to discover a means of rearing on a large scale the just-hatched fry of the more sedentary species to a sturdy adolescence. When that has been done (it has been achieved by the present writer in the case of the sea fish Cottus with demersal eggs) it would be possible to deposit the young fish in suitable localities on a large scale, with a reasonable prospect of influencing the local abundance of the species of fish in question.

For further details, see J. T. Cunningham, Natural History of the Marketable Marine Fishes of the British Islands (London, 1896); A Manual of Fish-Culture (Washington, 1897); Roché, La Culture des poissons artificiels (Paris, 1898); W. Garstang, Experiments on the Transplanta- tion of Marketed Fish (First Report of the North Sea Fisheries Investigation Committee, 1905).

PISCINA, a Latin word first applied to a fish-pond, and later used for any pool of water for bathing, &c., either natural or artificial, and also for a tank or reservoir. In ecclesiastical usage the term was given to a shallow stone basin (the French cuvette) placed near the altar in a church, with drains to take away the water used in the ablutions at the mass. “Piscinae” seem at first to have been mere cups or small basins, supported on perforated stems, placed close to the wall, and afterwards to have been recessed therein and covered with niche heads, which often contained shelves to serve as aumbries. They are rare in England till the 13th century, after which there is scarcely an altar without one. They frequently take the form of a double niche, with a shaft between the arched heads, which are often filled with elaborate tracing.

PISEK, a town of Bohemia, 55 m. S. of Prague by rail. Pop. (1900), 13,608, mostly Czech. It lies on the right bank of the Wottawa, which is here crossed by an interesting stone bridge of great antiquity. The most prominent buildings are the church of the Nativity, the town-hall, and a castle dating from the 15th century. The industries are iron and brass founding, brewing, and the manufacture of shoes, paper, cement and Turkish fezes. Feldspar, quartz and granite are quarried in the environs. The name of Pisek, which is the Czech for sand, is said to be derived from the gold-washing formerly carried on in the bed of the Wottawa (1571-1621).

In 1619 it was captured by the imperialist general, Karl Bonaventura de Longueval, Graf von Buquoy, and suffered so severely that the citizens opened their gates to his opponent, Ernst von Mansfeld. This was punished in October of the following year, when Duke Maximilian of Bavaria sacked the town and put nearly all the inhabitants to the sword. Pisek was one of the chief centres of the Hussites. It was occupied by the French in 1741.

PISIDIA, in ancient geography, the name given to a country in the south of Asia Minor, immediately north of Pamphylia by which it was separated from the Mediterranean, while it was bounded on the N. by Phrygia, on the E. by Lycaonia, Isauria and Cilicia, and on the W. and S.W. by Lycia and a part of Phrygia. It was a rugged and mountainous district, comprising some of the loftiest portions of the great range of Mt Taurus, together with the offshoots of the same chain towards the central table-land of Phrygia. Such a region was naturally occupied from a very early period by wild and lawless races of mountaineers, who were very imperfectly reduced to subjection by the powers that successively established their dominion in Asia Minor. The Pisidians are not mentioned by Herodotus, either among the nations that were subdued by Croesus, or among those that furnished contingents to the army of Xerxes, and the first mention of them in history occurs in the Anabasis of Xenophon, where they furnished a pretex to the younger Cyrus for levying the army with which he designed to subvert his brother’s throne, while he pretended only to put down the Pisidians who were continually harassing the neighbouring nations by their lawless forays (Anab. i. 1, 11; ii. 1, 4, &c). They are afterwards mentioned frequently by later writers among the inland nations of Asia Minor, and assume a more prominent part in the history of Alexander the Great, to whose march through their country they opposed a determined resistance. In Strabo’s time they had passed under the Roman dominion, though still governed by their own petty chieftains and retaining to a considerable extent their predatory habits (giving rise to such wars as that carried on by Quirinius, about 8–6 B.C.).

The boundaries of Pisidia, like those of most of the inland provinces or regions of Asia Minor, were not clearly defined, and appear to have fluctuated at different times. This was especially the case on the side of Lycia, where the upland
district of Milyas was sometimes included in Pisidia, at other times assigned to Lycia. Some writers, indeed, considered the Pisidians as the same people with the Milys, while others regarded them as descendants of the Solymi, but Strabo speaks of the language of the Pisidians as distinct from that of the Solymi, as well as from that of the Lydians. The whole of Pisidia is an elevated region of table-lands or upland valleys in the midst of the ranges of Mt. Taurus which descends abruptly on the side of Pamphylia. It contains several small lakes, and two of large size, Bey-Sheker Lake, the ancient Karalis, and the double lake now called the Egerdir Geul, of which the ancient name was Limnai. The latter is a fresh-water lake of about 30 m. in length, situated in the north of Pisidia on the frontier of Phrygia, at an elevation of 3007 ft. Karalis is a larger body, also of fresh water, and at a distinctly higher level above the sea. The only rivers of importance are the Cestrus and the Eurymedon, both of which take their rise in the highest ranges of Mt. Taurus, and flow down through deep and narrow valleys to the plain of Pamphylia, which they traverse on their way to the sea.

Notwithstanding its rugged and mountainous character, Pisidia contained in ancient times several considerable towns, the ruins of which have been brought to light, while others are still unknown. There were once several towns, (Acrinod, Hamali, Daniel, G. Hirschfeld, Radet, Sterrett, Lanckoronski, Ramsay, &c.), and they show to have attained under the Roman Empire to a degree of opulence and prosperity far beyond what we should have looked for in a country of predatory mountaineers. The most important of them are Termessus, near the frontier of Lycia, a strong fortress in a position of great natural strength and commanding one of the principal passes into Pamphylia; Cremna, another mountain fortress, north of the preceding, impeding over the valley of the Cestrus; Sagalassus, a little farther north, a large town in a strong position, the ruins of which are among the most remarkable in Asia Minor; Selge, on the right bank of the Eurymedon, surrounded by rugged mountains, notwithstanding which it was in Strabo's time a large and opulent city; and Antioch, known for distinction's sake as Antioch of Pisidia, and celebrated for the visit of St. Paul. This was situated in the extreme north-east of the district immediately on the frontier of Phrygia, between Lake Egerdir and the range of the Sultan Dagh and was reckoned in the Greek and earlier Roman period, e.g. by Strabo, as a city of Phrygia.

Beside these there were situated in the Roman province, the main tract of the Cestrus Cretepolis, Olbas, Pogia, Isinda, Etenna and Comama. Pednelissus was in the upper valley of the Eurymedon above Selge. The only place in the district at the present day deserving to be called a town is Isbarta, the residence of a pasha; it stands at the northern foot of the main mass of Mt. Taurus, looking over a wide and fertile plain which extends up to the northern chain of Taurus. North of this and immediately on the borders of Phrygia stood Apollonia, called also Mordiaeum. Large estates in Pisidia and the adjoining parts of Phrygia belonged to the Roman emperors; and their administration has been investigated by Ramsay and others.

We have no clue to the ethnic character and relations of the Pisidians, except that we learn from Strabo that they were distinct from the neighbouring Solymi, who were probably a Semitic race, but we find mention an early period in these mountain districts of various other tribes, as the Caball, Milmys, &c., of which, as well as the neighbouring Issaurians and Lycuaniacs, the origin is wholly unknown, and the absence of monuments of their languages must remain so. A few short Pisidian inscriptions have been published by Ramsay in "Revue des études anciennes" (1895, pp. 335-362). No inscriptions in these other languages are known.

W. M. RA.

PISO, the name of a distinguished Roman plebeian family of the Calpurnian gens which continued in existence till the end of the 2nd century A.D. Nearly fifty of its members were prominent in Roman history, but the following deserve particular mention.

1. LUCIUS CALPURNIUS PISO CAESONIUS, Roman statesman, was the father-in-law of Julius Caesar. In 58 B.C., when consul, he and his colleague Aulus Gabinius entered into a compact with P. Clodius, with the object of getting Cicero out of the way. Piso's reward was the province of Macedonia, which he administered from 57 to the beginning of 55, when he was recalled, perhaps in consequence of the violent attack made upon him by Cicero in the senate in his speech De provinciis consularibus. On his return Piso addressed the senate in his defence, and Cicero replied with the coarse and exaggerated invective known as In Pisonem. Piso issued a pamphlet by way of rejoinder, and there the matter dropped, Cicero being afraid to bring the father-in-law of Caesar to trial. At the outbreak of the civil war Piso offered his services as mediator, but when Caesar marched upon Rome he left the city by way of protest. He did not, however, definitely declare for Pompey, but remained neutral, without forfeiting the respect of Caesar. After the murder of the dictator he insisted on the provisions of his will being strictly carried out, and for a time opposed Antony. Subsequently, however, he became one of his supporters, and is mentioned as taking part in an embassy to Antony's camp at Mutina with the object of bringing about a reconciliation.

2. LUCIUS CALPURNIUS PISO, surnamed Prugi (the worthy), Roman statesman and orator, was born in 130 B.C. He is known chiefly for his lex Calpurnia repetundarum, which brought about the system of quaestiones perpetuae and a new phase of criminal procedure. As praetor (136) and consul (135) Piso fought against the slaves in Sicily. He energetically opposed Gaius Gracchus, especially in connexion with his corn law.

3. GNAEUS CALPURNIUS PISO, Roman statesman, was consul in 7 B.C., and subsequently governor of Spain and proconsul of Africa. In a.d. 17 Tiberius appointed him governor of Syria, with secret instructions to thwart Germanicus, to whom the eastern provinces had been assigned. The indignation of the people at the death of Germanicus, and the suspicion that Piso had poisoned him, forced Tiberius to order an investigation. Piso committed suicide, though it was rumoured that Tiberius, fearing incriminating disclosures, had put him to death.

See H. Schiller, Geschichte der römischen Kaiserzeit (1883), vol. i.

4. GAIS CALPURNIUS PISO, Roman statesman, orator and patron of literature in the 1st century A.D., is known chiefly for his share in the conspiracy of a.d. 65 against Nero (q.v.). He was one of the most popular men in Rome, partly for his skill in poetry and music, partly for his love of luxury and generosity. It is probably the last-named who is referred to by Calpurnius Siculus under the name of Meliboeus, and he is the subject of the panegyric De laude Pisonis.

PISSARRO, CAMILLE (1831-1903), French painter, was born at St Thomas in the Danish Antilles, of Jewish parents of Spanish extraction. He went to Paris at the age of twenty, and, as a pupil of Corot, came into close touch with the Barbizon masters. Though at first he devoted himself to subjects of the kind which will ever be associated with the name of Millet, his interest was entirely absorbed by the landscape, and not by the figures. He subsequently fell under the spell of the rising impressionist movement and threw in his lot with Monet and his friends, who were at that time the butt of public ridicule. Like Monet, he made sunlight, and the effect of sunlight on the changing nature, the chief subjects of his paintings, whether in the country round about Paris or in the colonies. About 1885 he took up the laboriously scientific method of the pointillists, but after a few years of these experiments he returned to a broader and more attractive manner. Indeed, in the closing years of his life he produced some of his finest paintings, in which he set down with admirable truth the peculiar atmosphere and colour and teeming life of the boulevards, streets and bridges of Paris and Rouen. He died in Paris in 1903.
PISTACHIO NUT—PISTOIA, SYNOD OF

Pissarro is represented in the Caillebotte room at the Luxembourg, and in almost every collection of impressionist paintings. A number of his finest works are in the collection of M. Durand-Ruel in Paris.

PISTACHIO NUT, the fruit of Pistacia vera (natural order Anacardiaceae), a small tree which is a native of Syria and generally cultivated in the Mediterranean region. Although a delicious nut and much prized by the Greeks and other Eastern nations, it is not well known in Britain. It is not so large as a hazel nut, but is rather longer and much thinner, and the shell is covered with a somewhat wrinkled skin. The pistachio nut is the species named in Gen. xliii. 11 (Heb. 15:2, Ar. bolm) as forming part of the present which Joseph's brethren took with them from Canaan, and in Egypt it is still often placed along with sweetmeats and the like in presents of courtesy. The small nut of Pistacia lentiscus, not larger than a cherry stone, also comes from Smyrna, Constantinople and Greece. P. lentiscus is the mastic tree, a native of the Mediterranean region, forming a shrub or small tree with evergreen pinnately-compound leaves with a winged stalk. “Mastic” (from masticare, to chew) is an aromatic resinous exudation obtained by making incisions in the bark. It is chiefly produced in Asia Minor and is used by the Turks as a chewing gum. It is also used as a varnish for pictures. P. terebinthus, the Cyprus turpentine tree, a native of southern Europe, Asia Minor and North Africa, yields turpentine from incisions in the trunk. A gall is produced on this tree, which is used in dyeing and tanning.

PISTIL, a term in botany for the female or seed-bearing organ of a flower (q.v.). The Lat. pistillum (diminutive from pisere, pistum, to pound), a pestle, a club-headed instrument used for crushing or braying substances in a mortar (q.v.), was taken as the name for this organ from its similarity in shape, and thence adapted in Fr. pistil about the middle of the 18th century. In its complete form a pistil consists of three parts—ovary, style and stigma, the bases of the flowers which become seeds, style (Gr. στύλος, pillar), and stigma (Gr. στυγμα, mark, στύγεω, to brand), the part which in impregnation receives the pollen.

PISTOIA, or PISTOIA (anc. Pistoriae), a town and episcopal see of Tuscany, Italy, in the province of Florence, from which it is 21 m. N.W. by rail. Pop. (1906), 27,127 (town); 68,131 (commune). It is situated on a slight eminence (210 ft.) near the Ombrone, one of the tributaries of the Arno. It is on the site of the Roman Pistoriae, which is hardly mentioned in ancient times, except for the destruction of Catiline's forces and the slaughter of their leader near it in 62 B.C., and as a station on the road between Florentia and Luca; and early still by Plautus, but only with jesting allusion to the similarity of the name to the word pistor (baker). Hardly any inscriptions of the ancient town have been found; but excavations in 1902 (see G. Pellegrini in Notizie degli Scavi, 1904, p. 241) in the Piazza del Duomo led to the discovery of a large private house, which belonged to the end of the 1st century B.C. Some mosaic pavements were found, belonging perhaps to the 3rd century A.D., while the house appears to have fallen into ruin at the beginning of the 5th. Remains of four subsequent periods were discovered above it. It was found that the tradition that the cathedral occupied the site of a temple of Mars was groundless; for the house appears to have extended under it. Aminiatus Marcellinus (5th century) mentions Pistoriae as a city of Tuscia Annannaria. During the middle ages Pistoia was at times a dangerous enemy to Florence, and the scene of constant conflicts between the Guelphs and Ghibellines; it was there that the great party struggle took place which resulted in the creation of the Bianchi and Nerli factions (see Dante, Inferno, xxiv. 121 to end). In 1302-06 it was besieged and eventually taken by the armies of Florence and Luca, and in 1235 it became subject to Castruccio of Lucca. In 1351 it was obliged to surrender to Florence, and thenceforth shared its fate.

The city is still surrounded by walls, dating from shortly after the siege of 1302-06; while two inner lines of streets represent two earlier and inner lines of wall. In the early development of architecture and sculpture Pistoia played a very important part; these arts, as they existed in Tuscany before the time of Nicola Pisano, can perhaps be better studied in Pistoia than anywhere else; nor is the city less rich in the later works produced by the school of sculptors founded by Nicola. In the 14th century Pistoia possessed a number of the most skilful artists in silver-work, a wonderful specimen of whose powers exists now in the cathedral—the great silver altar and frontal of St James, originally made for the high altar, but now placed in a chapel on the south side. The cathedral is partly of the 12th century, with a porch and facade with small arcades—in black and white marble, as is the case with several other churches of Pistoia—but was remodelled in the 13th century, and modernized inside in the worst taste. Besides the silver altar it contains many fine works of sculpture; the chief are the monument of Cino da Pistoia, lawyer and poet, Dante's contemporary (1337), by Cellino di Nese, surrounded by his scholars, and Verrocchio's finest work in marble, the monument to Cardinal Forteguerra (1474), with a large figure of Christ, surrounded by angels, in high relief. The clay model for it is in the South Kensington Museum. The monument has unfortunately been altered. The octagonal baptistery is by Cellino di Nese (1339). Among the earlier churches the principal is Sant' Andrea, enriched with sculpture, and probably designed by Gruamons and his brother Aedodatus in 1136; in the nave is Giovanni Pisano's magnificent pulpit, imitated from his father's pulpit at Pisa. Other churches of almost equal interest are S. Giovanni Fuorcivitas (so called because it was outside the line of the earliest, pentagonal, enceinte of the middle ages), with one of the long sides elaborately adorned with small arcades in the Pisian style, in black and white marble, also with sculpture by Gruamons (1162) on the facade. Within is a beautiful group of the Visitatio by Luca della Robbia. There is also a fine pulpit by Fra Guglielmo dell'Angelo of Pisa (1270). S. Bartolomeo in Fantano is an interesting 13th-century church, and S. Pietro in the Campo dei Miracoli is a fine church of the end of the 13th century with interesting frescoes of the school of Giotto. San Domenico, a noble church, begun in 1204, contains the beautiful tomb of Filippo Lazari by Bernardo and Antonio Rossellino (1462-1468). In addition to its fine churches, Pistoia contains many noble palaces and public buildings. The Palazzo del Commune and the Palazzo Pretorio, once the residence of the podestà, are both fine specimens of 14th-century domestic architecture, in good preservation. The quadrangle of the latter contains many well-painted armorial bearings of the podestât's. The Ospedale del Cepo, built originally in the 13th century, but remodelled in the 15th, is remarkable for the reliefs in enamelled and coloured terra-cotta with which its exterior is richly decorated. Besides various medallions, there is a frieze of figures in high relief extending along the whole front, over its open arcade. The reliefs consist of a series of groups representing the Seven Works of Mercy and other figures; these were executed by Giovanni Della Robbia between 1514 and 1525, and, though not equal to the best work of Luca and Andrea, are yet very fine in conception and modeling, and extremely rich in their general decorative effect. The last on the right was added in 1585 by Paladini.

The industries of Pistoia include iron and steel works, especially manufactures of glass, silk, macaroni, woolens, olive oil, ropes, paper, vehicles and fire-arms. The word "pistol" is derived (apparently through pistolea, a dagger—dagger and pistol being both small arms) from Pistoia, where that weapon was largely manufactured in the middle ages.

PISTOIA, SYNOD OF, a diocesan synod held in 1786 under the presidency of Scipione de' Ricci (1741-1810), bishop of Pistoia, and the patronage of Leopold, grand-duke of Tuscany, with a view to preparing the ground for a national council and a reform of the Tuscan Church. On the 26th of January the interesting barons of the Tuscan Church to the Tuscan bishops suggesting certain reforms, especially in the matter of the restoration of the authority of diocesan synods, the purging of the missals and breviaries of legends, the assertion of episcopal as against papal authority, the curtailting of the privileges of the monastic orders, and the better education of the clergy.
In spite of the hostile attitude of the great majority of the bishops, Bishop de' Ricci issued on the 31st of July a summons to a diocesan synod, which was solemnly opened on the 18th of September. It was attended by 233 beneficed secular and 13 regular priests, and decided with practical unanimity on a series of decrees which, had it been possible to carry them into effect, would have involved a drastic reform of the Church on the lines advocated by “Febronius” (see Febronianism).

The first decree (Decretum de fide et ecclesia) declared that the Catholic Church has no right to introduce new dogs, but only to preserve in its original purity the faith once delivered by Christ to His apostles, and is infallible only so far as it conforms to Holy Scripture and true tradition; the Church, moreover, is a purely spiritual body and has no authority in things secular. Other decrees denounced the abuse of indulgences, of festivals of saints, and of processions and suggested reforms; others again enjoined the closing of shops on Sunday during divine service, the issue of service-books with parallel translations in the vernacular, and recommended the abolition of all monastic orders except that of St Benedict, the rules of which were to be brought into harmony with modern ideas; nuns were to be forbidden to take the vows before the age of 40. The last decree proposed the convocation of a national council.

These decrees were issued together with a pastoral letter of Bishop de' Ricci, and were warmly approved by the grand-duke, at whose instance a national synod of the Tuscan bishops met at Florence on the 23rd of April 1787. The temper of this assembly was, however, wholly different. The bishops refused to allow a voice to any not of their own order, and in the end the decrees of Pistoia were supported by a minority of only three. They were finally condemned at Rome by the bull Autorem fidei of the 28th of August 1794. De' Ricci, deprived of the personal support of the grand-duke (now the emperor Leopold I.), exposed to pressure from Rome, and threatened with mob violence as a suspected destroyer of holy relics, resigned his see in 1791, and lived in Florence as a private gentleman until his death in 1810. In May 1805, on the return of Pope Pius VII. from Paris, he had signed an act of submission to the papal decision of 1794.

De' Ricci's own memoirs, Memorie di Scipione de' Ricci, vescovo di Prato e Pistoia, edited by Antonio Galli, were published at Florence in 2 vols. in 1865. Besides this his letters to Antonio Marini were published by Cesare Guasti at Prato in 1857; these were promptly put on the Index. See also De Potter, Vie de Scipione de' Ricci (3 vols., Brussels, 1828), based on a MS. life and a MS. account of the synod placed on the Index in 1829. There are many documents in Zobi, Storia civile della Toscana, vols. ii. and iii. (Florence, 1856). The acts of the synod of Pistoia were published in Italian and Latin at Pavia in 1788.

PISTOL, a small fire-arm designed for quick work and personal protection at close quarters, and for use in one hand. It was originally made as a single and also double-barrelled smooth bore muzzle-loader, involving no departure in principle from the ordinary fire-arms of the day. With the introduction of revolvers and breech-loading pistols and the application of “riffing” to musket barrels, came also, in the early half of the 19th century, the rifling of pistol-barrels.

History.—Pistols are understood to have been made for the first time at Pistoia in Italy, whence they receive their name. Caminelio Vitelli, who flourished in 1540, is the accredited inventor. The first pistols, in the 16th century, had short single barrels and heavy butts, nearly at right angles to the barrel. Shortly afterwards the pattern changed, the butts being lengthened out almost in a line with the barrels. These early pistols were usually fitted with the wheel-lock (see Gun). Short, heavy pistols, called “dagges,” were in common use about the middle of the 17th century, with butts of ivory, bone, hard wood or metal. A chiselled Italian dagg of 1620, for example, had a slightly bell-nosed barrel of about 8 in. in length and 14 bore. The German wheel-lock military pistols used by the Reiters, and those made for nobles and gentlemen, were profusely and beautifully ornamented. Pistols with metal butts were common in the 16th and 17th centuries, many beautiful specimens of which, silver-mounted, were made in Edinburgh and used by Highlanders. Duelling, when in vogue, caused the production of specially accurate and well-made single-barrelled pistols, reliable at twenty paces. The pattern of this pistol seldom varied, its accuracy at short range equaling that of more modern ones, the principle of a heavy bullet and light charge of powder being employed. The first double-barrelled pistols were very bulky weapons made with the barrels laid alongside one another, necessitating two locks and two hammers. There was also the “over and under” pistol, one barrel being laid over the other. This was a more portable weapon, only requiring one lock and hammer, the second barrel being turned round by hand, after the first had been fired, or, as an alternative, the flash-hole being adjusted to the second barrel by a key. These pistols were first made with flint and steel locks and subsequently for percussion caps. Double “over and under” pistols were also made with a trigger mechanism that served to discharge both barrels in turn.

Revolvers.—A revolver is a single-barrelled pistol with a revolving breech containing several chambers for the cartridges, thus enabling successive shots to be rapidly fired from the same weapon without reloading. The ordinary pistol is now, and has been for many years past, superseded by the revolver. The first revolver, fired with the percussion cap, was made with the whole of the barrels, six, seven or eight, revolving in one piece, and was known as the “pepper-box.” It was “single action,” i.e. the hammer was raised and the barrels rotated by the pull of the trigger. This weapon was cumbersome and no accurate aim could be taken with it owing chiefly to the strength and resistance of the main-spring and the consequent strong pull required on the trigger. The principle of a revolving breech to one barrel, which superseded the “pepper-box,” is an old one in the history of fire-arms, dating from the 16th century. At

PISTOL

Tower of London, but this was subsequently improved by introducing geared mechanism, by which the pull of the trigger or the cocking of the hammer, or both, do the work. There exists a pistol of the time of Charles I. which is rotated automatically as the hammer is raised.

In 1814 a self-acting revolver mechanism of a crude pattern was produced in England. Four years later Collier used a separate spring to rotate the chamber. In 1835, an American, Samuel Colt, produced and patented the first practical revolving pistol, the idea of which was obtained by him, it is stated, from an ancient "revolving" weapon in the Tower of London. The chambers of the first Colt revolver were loaded with powder and bullets from the muzzle end, and each chamber had a nipple that required to be capped. It was the invention of the copper cap that made the Colt revolver possible. Under the old priming system with exposed powder in a pan the difficulty of separate and effective ignition with the revolving cylinder was almost insuperable.

The first American revolver makers caused the cocking of the hammer to revolve the cylinder, while the English makers effected this by the pull of the trigger. In 1835, Adams of London, and also Tranter of Birmingham, brought out the double-action revolver, in which the revolution of the cylinder could be effected by both these methods. When the revolver is cocked and fired by pressing the trigger, greater rapidity of fire is obtained than when the hammer is cocked with the thumb, but accuracy is impaired, as the trigger requires a long pull and considerable force in order to compress the mainspring and revolve the cylinder. The double action revolver was, therefore, a great advance on the single action, enabling the first and also following shots, if desired, to be accurately fired by a moderate pressure of the trigger after the hammer had beencocked by the thumb; or, alternatively, the revolver could be forward on the frame of the pistol. The extractor, being fast to the pivot, retained the cartridges until the chamber was pushed clear of them. Then the chamber was made to swing on one side, as in the Colt pistol illustrated, enabling all the cartridges to be simultaneously extracted. Finally, self-extracting revolvers with jointed frames were introduced, in which the dropping of the barrel forces out the extractor as in an ordinary double gun, the extractor acting simultaneously in all the chambers of...
PISTOL

the pistol. A spring returns the extractor to its place when the empty cartridge cases have been ejected, and brings the barrel to an angle of about 45°, for convenience in loading. The soundness and rigidity of the weapon depend upon the efficiency of the connexion between the barrels and the standing breech, and a top snap bolt has proved the strongest and handiest with the pistol, as with the shot-gun.

This type of revolver originated with Messrs Smith & Wesson, but they and other gunmakers have greatly improved upon the original model. Between the American pattern and the English, as made by Messrs F. Webley & Son, the chief difference is that in the Smith & Wesson the holding-down bolt or catch is upon the barrel, and it engages with the top of the standing breech; whereas in the Webley the bolt is upon the standing breech and grips the extremity of the hinged barrel. Neither mechanism is as strong as could be wished if heavy charges of smokeless nitro-compounds are to be used. This hinged type of revolver is most convenient for use on horseback, as the pistol can be opened, the cartridges extracted and the weapon reloaded with one hand.

The Colt's Double-Action Revolver, calibre .38, model 1866, used in the United States army, consists (figs 7 and 8) of the barrel (B), the cylinder (C) with six chambers, the frame (F), and the firing mechanism, all of steel. The muzzle velocity, with a charge of 16 grains of black powder and a bullet of 150 grains of lead, is about 708 ft. per second, giving at 25 yards a penetration of about 5 in. in pine.

The lock mechanism consists of the hammer (h), with its stirrup (r), stirrup pin (p), strut (s), strut pin (i), strut spring (q); the trigger (t), the rebound lever (l), the handle (a), with its spring (s); the cylinder bolt (g), with its spring (x); the locking lever (v); the main spring (m), and rebound lever spring (n). The hammer (h), trigger (t), and rebound lever (l) are pivoted on their respective pins, which are fastened in the left side of the frame. The lower end of the rebound lever spring (n) is secured to the frame and the free end bears under the rear end of the rebound lever so that the latter, when the trigger is released, cams the hammer back to its safety position, and forces the trigger forward. Pressure upon the trigger causes its upper edge to engage the strut, and thereby raises the hammer until nearly in the full-cock position, when the strut will escape from the trigger, and the hammer, under the action of the mainspring, will fall and strike the cartridge. A projection on the upper part of the trigger, working in a slot in the frame, prevents the cylinder from making more than one-sixth of a revolution at a time by entering one of the grooves nearest the rear end of the surface of the cylinder. When the cylinder is swung out of the frame, these parts are arranged to prevent the cocking of the hammer. The cylinder bolt is pivoted on the trigger pin, and its spring, bearing on the rebound lever arm, causes the nose of the bolt to project through a slot in the frame ready to enter one of the corresponding cuts in the cylinder surface. During the first movement of the trigger in cocking the revolver, the nose of the bolt is withdrawn, allowing free rotation of the cylinder. The object of the bolt is to prevent rotation of the cylinder in transportation. The hand is attached by its pivot to the trigger, and, as the latter swings on its pin when the hammer is cocked, the hand is raised and revolvs the cylinder, and also serves to lock the cylinder in position at the time of firing. An abutment on the side plate supports the hand spring in rear. The spring ensures the engagement of the hand with the ratchet (y). The revolver is cocked by hand by withdrawing the hammer by the pressure of the thumb until its full-cock notch engages in the rear sharp corner of the trigger. Pulling the trigger then releases the hammer, allowing its firing pin (f) to move forward and strike the cartridge.

The locking lever is pivoted by its screw in a recess in the left side of the frame, and so connected with the latch that it locks the hammer and trigger when the latch is pushed to the rear for opening the cylinder, and does not unlock them until the cylinder is positively closed and is locked by the latch. The cylinder revolves and is supported on a central arbour of the frame (E). The arbour consists of the cylinder and is terminated in rear by the ejector with a ratchet (y). Pushing against the front end of the ejector rod will empty the chambers, the cylinder being swung out for loading. The thumb-piece of the latch (j) slides to the rear in the left side of the frame, unlocking the cylinder for opening, but upon closing the cylinder, the body of the latch firmly enters a recess in the ejector, locking the cylinder in position for firing.

One great disadvantage of revolvers is the escape of gas at the opening between the breech of the barrel and the cylinder.

This escape corrodes the surrounding parts and also materially diminishes the pressure in the barrel and the consequent velocity of the bullet. In the Nagant revolver, adopted by Russia, this disadvantage has been overcome by employing a long cartridge case which extends beyond the nose of the bullet and bridges the gap between barrel and cylinder as the cylinder is moved forward. A "mitrailleuse" pistol has also been constructed by the Braendlin Armoury Co., Ltd., on the "pepper-box" principle, with fixed barrels, either four or six, arranged in pairs, and a special striking mechanism, in which there is no revolving chamber and no escape of gas at the breech. It gives stronger shooting than a revolver, but is more cumbersome, and has the serious defect that the shock of the discharge of one barrel sometimes prematurely fires a second barrel.

In 1865, Sharp, an American, patented an invention to remedy the escape of gas, in which the four barrels of the pistol were drilled the full length out of one block of metal. The barrels were slid forward by an under lever to load, and the firing was effected by a revolving head to the hammer, set by the action of cocking the pistol.

About 1878 Messrs Lancaster introduced both two- and four-barrelled hammerless pistols, in which an internal hammer was worked by the pull of the trigger. In all the three weapons

FIG. 6.—Pepper-box revolver.

FIGS. 7 and 8.—Colt double-action revolver.
above mentioned, extraction and reloading were slow processes, which made them unsuited for use on horseback.

Hammerless Revolver.—The Smith & Wesson pocket pistol is one of the safest weapons of the size made. There is no hammer or equivalent protuberance to catch as the pistol is drawn from the pocket; or to entangle if the weapon falls. An automatic safety bolt, whose length lies half across the palm of the hand, and ensures certainty of freedom at the time of shooting, blocks the action until the pistol is firmly gripped for use.

Breech-loading Pistols.—Although the revolver has for many years practically superseded the pistol, some breech-loading varieties of pistols are still made—the small pocket pistol, for example, and occasionally the heavy double-barrelled horse pistol. At one time these latter were much used, of 577 bore, as well as the well-known short, large-bore pistol known as the Derringer, usually of .41 calibre. The double horse pistol is now usually made for a 20-bore cartridge and spherical bullet, and weighs about 34 lb. It is a clumsy, but effective weapon, and fires a charge of 13 drams of powder without unpleasant recoil. The duelling pistol, as made by Gartine Renette of Paris, is capable of wonderfully accurate shooting, firing a 9 millimetre spherical bullet and about 12 grs. of powder. This weapon is far superior in accuracy to a revolver. Single-barrelled pistols, chambered for the .22 or 297/320 calibre cartridges, with a barrel of from 6 to 10 in. in length, are also made, and when fitted with a detachable metal stock form excellent little weapons for target practice.

Automatic Revolver.—The Webley-Fosbery automatic revolver is a weapon of a distinctly new design, in which for the first time the principle of utilizing the recoil of each shot to operate the mechanism is applied to the revolver. In appearance the weapon is very similar to the Webley service model. The simple pressure of the forefinger on the trigger, the pressure being released between each shot, is all that is required to fire the six successive shots of the revolver. It is supplied with a safety bolt worked by a thumb-piece, andMessrs Webley have introduced a clip loader which enables the six chambers to be reloaded at the same time. This weapon has met with considerable success, and is made in two calibres, the .455, 6 shot, 2 lb 5½ oz. in weight; and the .38 model, 8 shot, 2 lb 3 oz. in weight.

Automatic Pistols.—These weapons are the latest and most advanced type of pistol, and it is anticipated by experts that they will ultimately supersede the revolver. They are made with one barrel and a magazine, on the principle of the repeating rifle, thus doing away with the escape of gas that takes place in revolving between the chamber and the barrel.

Automatic pistols are so constructed that the force of the recoil is utilized to open the breech, extract the empty case, cock the pistol, reload the chamber with the top cartridge from the magazine, and close the breech, leaving the pistol ready to fire on again pressing the trigger.

The Mauser "self-loading" pistol (fig. 9) is one of the earliest of the successful automatic weapons. It is usually .300 calibre, 10 shot, with a metal clip loader from which the cartridges are "stripped" into the magazine, weight 2½ lb, length of barrel 8½ in., bullet 85 grains, initial velocity about 1394 ft. per second.

The barrel (1) and body (2) are in one piece; the latter contains the bolt (3). The barrel and body slide on the frame (4); the 10-shot magazine (5) and the stock are in one piece with the frame, and the lock frame (6) and lock-work are contained in the rear part of it. The bolt (3), which is square, slides in the body, and is kept pressed up to the chamber by the bolt spring (8); the rear end of this bolt spring bears against the block (9). The striker and extractor are contained in the bolt. The bolt is locked by the bolt-lock (10). This is slotted through the centre and fits on to the projection (11) under the body; it is supported at the moment of firing by a projection on the lock frame (12); the top of the bolt-lock has two teeth (13), which in the loaded and cocked position fit into two recesses in the bolt, and the bottom of its front end [in front of the body attachment (11)] has another tooth (14) which bears on the rocker (15). This rocker is pivoted at its bottom corner. The mainspring (16) bears in front against the rocker, and in rear against the hammer mechanism. The action of the mechanism is
PISTOL

The operation of the pistol is as follows: When a charged magazine (M) is inserted, the slide (S) is drawn out to the rear by hand, thereby cocking the hammer (H). In this position of the slide, the carrier (C) and carrier spring in the magazine raise the topmost cartridge so as to bring it into the path of the bolt (K). On releasing the slide, it, with the bolt, is carried forward by the spring, which projects the bolt as the frontmost cartridge into the chamber (B). As the slide approaches its forward position the front of the bolt encounters the rear end of the barrel and forces the latter to its forward position. During this forward movement the barrel swings forward and upward on the links (I, o), and thus the locking ribs (p) on the barrel are carried into the corresponding locking recesses in the slide. The barrel and slide are thereby interlocked, and the pistol ready for firing.

A slight pull on the trigger (d) now serves to move the rear (a) so as to release the hammer (h) and fire a shot. The force of the powder gases drives the bullet from the barrel and exerts a rearward pressure on the bolt, and, overcoming the inertia of the slide and the tension of the retractor spring, causes the slide and the barrel to recoil together. After moving rearwards together, for a distance, enough to ensure the bullet having passed from the barrel, the downward swinging movement of the barrel releases the latter from the slide and stops the barrel in its rearmost position. The mechanism of the slide can now be continued so long as there are cartridges in the magazine, each discharge requiring only the slight pull on the trigger. The pistol is provided with a safety device (a) which makes it impossible to release the hammer unless the slide and barrel are in their first forward position and interlocked.

In the Borchardt-Leuger pistol (fig. 11) the bolt is solidly supported at the moment of firing by a toggle joint. The barrel (1 A) and body (1 B) slide in the frame (1 C), the bolt (2) slides in the body and is held up to the breech by the toggle joint 3 and 4 and the pins 5 and 7, which secure the links of the toggle to the body. The centre of pin (6) is below those of the other pins so that the joint cannot fail at the moment of firing. On the rear link (3 A) and there is a swivel (8) which is connected to the recoil spring (10) in the grip. This pistol is fired by a spring striker, like a rifle, instead of by a hammer. The striker is within the bolt; it is cocked in the recoil position by a claw on the end of the front link (3 A) and held thus ready to fire by the nose of the trigger sear, these engaging with a projection (8 A) on the side of the striker. The magazine (8 shot) is in the grip. The action is as follows: the first cartridge is loaded from the magazine by pulling back the toggle joint. As soon as the toggle joint is released the recoil spring acts and forces the bolt home, with the cartridge in front of it. On pressing the trigger the barrel and body recoil a little. Then the toggle joint comes
against curved ramps on the sides of the non-recoiling frame and is forced up, so that thereafter the bolt alone recoils (the ejector is similar in principle to that of a rifle). The recoil spring then acts as before on reloading.

Other varieties of the automatic pistol are the "Mannlicher," the "Mauser," the "Bergmann" and the "Webley." The last, being simple in construction, small and light, weight 18 oz. and length over all only 6 1/2 in., may be clasped as a pocket pistol.

**Qualities of Automatic Pistols.**—In reference to the general qualities of automatic pistols, while these weapons have the advantage over revolvers of longer range and greater rapidity of fire and recharging, on the other hand they are necessarily more complicated in their mechanism, which has to do the work of extraction, reloading and cocking that in the revolver is done by hand. A stoppage may occur through a cartridge missing fire, or continuous uncontrolled fire may take place through the trigger spring breaking until the magazine is exhausted. Their action is also to some extent uncertain, as it depends on the recoil of the discharge, which may be affected by variables in the cartridge; also the effective automatic working of the moving parts depends upon their cleaning and lubrification. Automatic pistols, like revolvers, are intended for personal defence at short range and for sudden use in emergencies, simplicity of mechanism and certainty of action are in their case of paramount importance. There is usually no time to rectify a stoppage or jam, however slight. From a military point of view, therefore, before the revolver is altogether superseded by the automatic pistol, it is most desirable that the latter should be as certain in its action under service conditions as the former. Some automatic pistols, as already stated, are sighted up to 1000 yards, and provided with attachable butts. The practical value of these improvements is open to question, as the sighting of a pistol differs materially when used with and without a butt, and under no circumstances can the accuracy of shooting of a pistol, even with a butt, equal that of a carbine.

The tendency in automatic pistols has been to reduce the bore to .3 in., and increase the muzzle velocity, on the lines of modern small-bore rifles. These, again, would appear to be advantages of minor importance in a weapon intended for use at short range in the field, where a heavy bullet of fairly large diameter, with a moderate muzzle velocity, has a more immediate and paralysing effect, and is therefore, from this point of view, and particularly in savage warfare, preferable to a small projectile of high muzzle velocity.

**PISTOLE,** the French name given to a Spanish gold coin in use from 1537; it was a double escudo, the gold unit, and was worth 16s. 11d. sterling. The name was also given to the **lois d’or** of Louis XIII. of France, and to other European gold coins of about the value of the Spanish coin.

**PISTON** (through Fr. from Ital. pistone or pestone, a great pestle, from Late Lat. pistare, to pound, a frequentative form of classical Lat. pisare), in the steam engine, a disk or partition placed inside the cylinder, from end to end of which it moves alternately under the pressure of the steam. By means of the "piston-rod" attached to it this forward and backward motion is communicated to the machinery which the engine is employed to drive, and is in most cases converted into rotary motion by a "connecting-rod" one end of which is joined to the "crankshaft" while the other turns the crank on the shaft. The piston in gas, oil and air engines has a similar function, but in a pump, instead of imparting motion, it has motion imparted to it by some prime-mover. In every case the piston must fit the cylinder so accurately that as little as possible of the working fluid, whether it be steam, gas or water, can escape past it, packing of various forms being commonly placed round its periphery in order to secure this fit. In music, the valves which in certain wind instruments, such as the cornet, enable the player to change the length of the air-column and thus lower the note produced, are known as pistons. (See VALVES.)

**PIT** (O. E. pyt, cognate with Du. put, Ger. Pfitsche, &c., all ultimately adaptations of Lat. puteus, well, formed from root pu-, to cleanse, whence purus, clean, pure), a term of wide application for a hole, cavity or excavation in the earth or other surface; thus it is applied to the excavations made in the ground for the purpose of extracting minerals, e.g. chalk, gravel or sand, or for carrying on some industry, e.g. tan-pit, saw-pit, or to the group of shafts which form a coal-mine. Roots and other vegetables can be stored in the winter in a pit, and the term is thus transformed to a heap of such vegetables covered with earth or straw. The word is also used of any hollow or depression in a surface, as in the body, the arm-pit, the pit of the stomach, or on the skin, as the scars left by small-pox or chicken-pox. As applied to a portion of a building or construction, the word first appears for an enclosure, often sunk in the ground, in which cock-fighting was carried on, a "cock-pit." It would seem a transference of this usage that gave the common name to that part of the auditorium of a theatre which is on the floor, the French parterre. In the United States a special usage is that of its application to that part of the floor space in an exchange where a particular branch of business is transacted; thus in the Chicago Board of Trade, transactions in the grain trade are carried on in what is known as the "Wheat Pit."

In Scottish legal history there was a hereditary privilege which in Latin is termed furca et fossa, "fork (i.e. galleries) and pit." Here the term has usually been taken to refer to the drowning-in, in which women criminals were put to death; others take it to refer to an ordnance. There is a parallel phrase in M. Dutch, *puste eckelen*; here *puste* is the pit in which women were buried alive as a penalty.

**PICTAIRN,** an island in the mid-eastern Pacific Ocean, in 25° 3’ S., 130° 6’ W., belonging to Great Britain. It lies south of the Paumotu archipelago, 100 m. from the nearest member of this group. Unlike the majority of the islands in this region, it is without coral reefs, but rises abruptly with steep and rugged cliffs of dark basaltic lava. The extreme elevation is over 2000 ft., and the area 2 sq. m. The soil in the valleys is volcanic and fertile, but the gradual utilization of natural timber increases the liability to drought, as there are no streams. The climate is variable and rainy. Stone axes, remains of carved stone pillars similar to those of Easter Island, and skeletons with a pearl-musel beneath the head have been found in the island, though it was uninhabited when discovered by Philip Carteret in 1767. Pitcairn was the name of the midshipman who first observed it.

The island was destined to become the scene of a curious social experiment. On the 28th of April 1789 a mutiny broke out on board the "Bounty," then employed by the British government in conveying young bread-fruit trees from Tahiti to the West Indies. The commander, Lieutenant William Bligh, was set adrift in the launch with part of the crew, but managed to make his way to Timor in the Malay Archipelago. The twenty-five mutineers at first all returned to Tahiti. Some remained, and six of these were ultimately court-martialled in England, three being executed in 1792. Meanwhile in 1790 a party consisting of Fletcher Christian, the leader of the mutiny, eight Englishmen, six Polynesian men and twelve Polynesian women had taken possession of Pitcairn Island and burned the "Bounty." Treachery and debauchery filled the first years of the annals of the beautiful island. By 1800 all the men were dead except Alexander Smith, afterwards known as John Adams, who rose to a sense of his responsibility and successfully trained up the youthful generation left in his charge. An American vessel, the "Topaze," discovered the strange colony in 1808; again, by accident. It was visited by the "Briton," Captain Sir F. Staines, and the "Tagus," Captain Fipon, in 1817; and by the exploring ship "Blossom" in 1825. On the death of John Adams on the 29th of March 1829 George Hunn Nobbs, who had settled at Pitcairn in 1828, was appointed pastor and chief magistrate. Through fear of drought the islanders removed to Tahiti in 1830, but disapproved of both the climate and the morals of this island, and returned to Pitcairn in 1831. Shortly after this an adventurer named Joshua Hill appeared, and, claiming government authority, tyrannized over the islanders till his removal by a British man-of-war in 1838. In 1856 the whole of the islanders—60 married persons and 134 young men, women and children—were landed on
PITCAIRNE, A.—PITCH, MUSICAL

Norfolk Island, but in 1852 two families chose to return, and their example was afterwards followed by a few others. Visited in 1873 and 1878 the colony was found in excellent order, but by the end of the century it was stated that intermarriage was bringing a deterioration of intellect, morals and energy, and that the islanders would probably drift into imbecility. Later accounts made it appear that this was an exaggeration, although the standard of morality was unquestionably low on the whole.

In religion the islanders are Seventh Day Adventists. "They have adopted an extraordinary patois, derived from the language of the Tahitian women who accompanied the mutineers of the "Bounty" to Pitcairn Island, although most of the adults can speak the English language fairly well" (R. T. Simons, Report, 1903). The island is a British colony by settlement, and is within the jurisdiction of the High Commissioner for the Western Pacific (since 1858). There is a governing body chosen from among the islanders, the constitution of which has been altered more than once owing to internal jealousies, &c. The island produces sweet potatoes, yams, melons, bananas and other fruits, arrowroot and coffee. Goats and chickens run wild. Some trade is carried on with Mangareva in a vessel owned by the islanders. The population is about 170.

PITCAIRNE, ARCHIBALD (1652–1713). Scottish physician, was born at Edinburgh on the 25th of December 1652. After obtaining some classical education at the school of Dalkeith, Pitcairne entered Edinburgh University in 1668, and took his degree of M.A. in 1671. Having been sent to France for the benefit of his health, he was induced at Paris to begin the study of medicine, and after courses at Edinburgh and Paris he obtained in 1680 the degree of M.D. at Rheims. He began practice at Edinburgh, and in a short time acquired so great a reputation that in 1692 he was appointed professor of medicine at Leiden. Among his pupils were Richard Mead and H. Boerhaave, and both of them attributed much of their skill to what they had learned from Pitcairne. In 1693 Pitcairne returned to Scotland to marry a daughter of Sir Archibald Stevenson, an eminent physician in Edinburgh. The family objected to her going abroad, so he did not return to Leiden, but settled once more in Edinburgh. He rose to be the first physician in Scotland, and was frequently called into consultation both in England and Holland. Soon after his return to Edinburgh, feeling the great want of the means of anatomical study, he importuned the town council to permit himself and certain of his medical friends to treat without fee the sick paupers in "Paul's Work," on condition of being allowed to dissect such of the bodies as were unclaimed by their relatives, and therefore had to be buried at the town's expense. Strangely enough this proposal was strongly opposed by the chief surgeons of the place, but ultimately the town council had the good sense to comply with Pitcairne's request, and in this way he may be said to have the credit of laying the foundation of the great Edinburgh school of medicine.

Pitcairne's medical opinions are chiefly contained in a volume of Dissertations medicae which he published in 1701 (2nd ed., 1713). In these he discusses the application of geometry to physic, the circulation of the blood in the smaller vessels, the difference in the quantity of the blood contained in the lungs of animals in the womb and of the same animals after birth, the motions by which food becomes fit to supply the blood, the question as to inventors in medicine (in which he repels the idea of certain medical discoveries of modern times having been known to the ancients, especially vindicating for Harvey the discovery of the circulation of the blood, and refuting the view that it was known to Hippocrates), the cure of fevers by evacuating medicines, and the effects of acids and alkalies in medicine. Pitcairne was a good classical scholar, and wrote Latin verses, occasionally with something more than mere imitative cleverness and skill. He was supposed to be the author of a comedy, The Assembly, or Scotch Reformation, and of a satirical poem Babel, containing witty sketches of prominent Presbyterian divines of the time, whom, as a loudly avowed Jacobite, he strongly disliked. He was prone to irreverent and ribald jests, and thus gained the reputation of being an unbeliever and an atheist, though he was a professed deist. The stories about his over-indulgence in drink are probably exaggerated. He was repeatedly involved in violent quarrels with his medical brethren and others, and once or twice got into scrapes with the government on account of his independent political utterances. Among his friends, however, he was evidently well liked, and he is known to have acted with great kindness and generosity to deserving men who needed his help. Thomas Ruddiman, the Scottish scholar, for example, was rescued from a life of obscurity by his encouragement and assistance, and by no one was his memory more gratefully cherished. Mead, too, appears never to have forgotten what he owed to his old teacher at Leiden. A son of Pitcairne's had gone out in the rebellion of 1715, and, having been condemned to death, was saved by the earnest interposition of Mead with Sir Robert Walpole. He pleaded, very artfully, that if Walpole's health had been bettered by his skill, or if members of the royal family were preserved by his care, it was owing to the instruction he had received from Dr Pitcairne. Pitcairne died in Edinburgh on the 20th of October 1713. He had been a great collector of books, and his library, which is said to have been of considerable value, was, through the influence of Ruddiman, disposed of to Peter the Great of Russia.

PITCH. (1) (O. Eng. pīc, an adaptation of Lat. pīx, pīcis, Gr. πίσσα, πίτα, allied with Gr. πῦρ, pine-tree, Lat. pinus), the name of various substances of dark colour and of extremely viscous and tenacious consistency when subjected to heat. Strictly the term is applied to the resinsus substance obtained as a solid residuum by the distillation of wood-tar (see TAR), or the non-resinous substance similarly produced from Coal-tar (q.v.). The name is also applied to the natural mineral substances, i.e. asphalt or bitumen (q.v.). (2) A noun of various meanings which are somewhat difficult to connect with the verb from which they apparently must be derived. "To pitch" means primarily to thrust in or fix a stake or other pointed object into the ground, hence to place in a fixed position, set in order, cast or throw, hence to incline or slope. The etymology is obscure, but it appears in Northern dialects as "pick," of which it may be a variant; there is some difficulty in connecting this form with "pick," variant of "pike" (q.v.).

PITCH, MUSICAL. The pitch of a musical sound is usually defined by its absolute position in the scale and by its relative position with regard to other musical sounds. It is precisely defined by a vibration number recording the frequency of the pulsations of a tense string, a column of air, or other vibrator, in a second of time. In Great Britain and America the complete vibration number is expressed in terms of the overtones of a pendulum as the unit; elsewhere the vibration in one direction only (swing one way of the pendulum). The official standard is the French, dating from 1859, preserved by a tuning-fork vibrating 870.0 (double vib. 435.45) at a temperature of 15°C (59°Fahr.) in a second. The vibration number stated in the specification that the Diapason Normal is 870 (435), which for comparison will be here adhered to. The natural basis for a standard musical pitch is the voice, particularly the male voice, which has been of greater importance historically. There is no reason to suppose the human voice has varied, during the period of which we have evidence, more than other physical attributes. The only difference to be reckoned with may be in recent tendencies of solo vocalists to sing for effect, and so to
extend the compass of the voice upwards. Otherwise we may assume no disturbing alteration has taken place for more than 2000 years in its position and extent. Vibrations increase in rapidity as a note rises and decrease as it falls. Any note may be a pitch note; for orchestrists custom has settled upon $d^4$ in the treble clef, for organs and pianos in Great Britain $c^2$, and for modern brass instruments $b^4$ flat.

We are not without a clue to the pitch usual in the classic Greek and Alexandrian ages: the vocal octave to which the lyre was adapted was noted as from $e$ to $e'$. As in chorus baritone and low tenor singers always prevail, $d-d'$, at French or at medium pitch, would really be the Greek singing octave; we may therefore regard it as a tone lower than that to which we are accustomed. But to sing the lower Greek modes in or near the vocal octave it was necessary to transpose (μεταδόσε) a fourth upwards, which is effected in modern notation by a flat placed upon the $b$ line of the staff; thus modulating from our major key for the low $F$, but if a larger organ is built, as we shall see, must be done with the history of our subject, ultimately influencing the ecclesiastical chant and lasting until the 17th century of our era. It does not appear from any evidence that the keyboards—when there were more than one—of the early organs were arranged for transposition, but it is certain that the Flemish harpsichords to 1650 were made with double keyboards to accommodate it (see Hipsik's History of the Pianoforte, 1897).

But a positive identity of pitch cannot be claimed for any period of time, and certainly not for the early organs; the foot-rule of the organ-builder, which had to do with the lengths of the pipes, and which varied in every country and province, could easily cause a difference of a semitone. Scale and wind-pressure are also important factors. But with all these often opposed conditions, we find less variation than might be expected, the main and really important divergence being due to the necessity of transposition, which added a very high pitch to the primarily lower one.

The first attempt to define pitch would seem to have been Arnold Schlick (Musica ausgeteucht und ausgezogen, Heidelberg, 1511), who gives a measure, a line of 43 French inches which, he says, multiplied sixteen times, should be the lowest $F$ of a small organ. He gives no diameter or wind-pressure. Dr A. J. Ellis used this indication to have an organ pipe made which with one-sixteenth diameter and a wind-pressure of 33 in., at one-fourth Schlick's length, gave $f'$ 301-6, from which he derived a just major third of $a' 377$, which would compare very well with an old Greek $a'$. Schlick goes on to say the organ is to be suited to the choir and properly tuned for singing, that the singer may be forced to sing too high or too low and the organist have to play chromatics, which is not handy for every one. Further, he says pitch cannot be exactly defined, because voices vary; he nevertheless gives the measure above mentioned, as if all others are to be used to bring in the still lower $C$, then this $C$ must be of the same measurement, the reason being that a greater part of church music ends in "grambus," a word understood by Schlick's editor to mean the transposition of a fourth. The larger high-pitch organ will therefore be at $d'$ 302-6. The Halberstadt organ, about which so much has been written, was, according to Praetorius (Syntagma musicum, Wölfenbüttel, 1618), built in 1636, and repaired and rebuilt 1495. He gives the longest pipe of this organ, $B$ natural, as 31 Buckingham feet, and the circumference 33 ft. He further tells us this pitch was a tone, nearly a tone and a half, higher than a suitable church pitch (Chorton), for which he gives a diagram. Dr Ellis had pipes (now preserved in the Royal Institution, London) made to reproduce both these pitches at 31 in. wind-pressure. The Halberstadt pitch was found to be $d'$ 305-8; the Chorton, 424-2. Ellis used mean-tone temperament in calculating this lower pitch; but as he used just intonation for the Halberstadt, it seems preferable to substitute it for the Chorton, thus reducing it to $d'$ 424-8. Praetorius's Cammeron, or chamber pitch, formulated in his diagrams for voices and instruments, is, he says, a whole tone higher; equivalent, therefore, to $a' 475-65$. Nearly all the German organs in his time were tuned to this higher pitch. Ellis offered the suggestion of a much higher pitch for this Cammeron in his lecture "On the History of Musical Pitch," read before the Society of Arts, London (Journal Soc. Arts, March 5, 1880), but the present writer is unable to accept it. The lower vibration number is justified by due consideration of the three divisions of the male voice, bass, tenor and alto, as given by Praetorius, whose Cammeron very closely corresponds with Bernhardt Schmidt's Durham organ, 1663-1668, the original pitch of which has been proved by Professor Armes to have been $a' 474-1$. The Halberstadt pitch is nearly a semitone higher, which again agrees with the statement of Praetorius, and also Schlick's high C organ. Yet it would seem there had been a still higher pitch used in the old ecclesiastical music. Upon this interesting question Praetorius is confused and difficult to understand, but he never wavers about the transposition of a fourth. In one passage he distinctly says the old organ high pitch had been a whole tone above his Cammeron, with which we shall find his tertia minore combines to make the required interval. The tertia minore, or inferior, is used by Praetorius to describe a low pitch, often preferred in England and the Netherlands, in Italy and in some parts of Germany. An organism, instead of transposing a whole tone down from the Cammeron, would for the tertia minore have to transpose a minor third. A corroboration of this pitch is found in A. Silbermann's great organ in Strasbourg minster (1717-1716), the pitch of which, taken in 1780 and reduced to 50th Fahr. (as are all pitches in this article), is $a' 393-2$. An old organ at Versailles (1780) was very near this example, $a' 395-8$. Sir Frederick Goring Ouseley (vide Ellis's lecture) regarded the French ton de chappelle as being about a minor third below the Diapason Normal, $a' 435$, and said that most of the untouched organs in the French cathedrals were at this low pitch. Strasbourg was French territory in 1713, but Silbermann's organ is not quite a whole tone below. Ellis quotes an organ at Lille, $d' 347-2$, but no other instance of the supposed pitch is known. Thus the French cathedrals might or might not have a minor third, or, as we shall see later, a whole tone, had replaced the earlier fourth. Sir Frederick Goring Ouseley's comparison of the choir and chamber pitches of Orlando Gibbons (vide Ellis's lecture) clearly shows the minor third in Great Britain in the first half of the 17th century. But the narrowing continued. Bernhardt Schmidt, better known in England as Father Smith, was invited about 1660 to build the organ for the Chapel Royal, Whitehall; two years later he built the organ in Durham Cathedral $d' 474-1$, difference a whole tone, and practically agreeing with the Cammeron of Praetorius. The Hampton Court organ of 1690 shows that Schmidt had further lowered his pitch a semitone, to $d' 441-7$. What happened at Durham was that at some subsequent date the pipes were shifted up a semitone to bring the organ into conformity with this lower pitch, with which it is probable Schmidt's organs in St Paul's and the Temple, and also Trinity College, Cambridge, agreed. This lowering tendency towards the low church pitch, and the final adoption of the latter as a general mean pitch throughout the 18th century, was no doubt influenced by the introduction of the violin, which would not bear the high tension to which the
PITCH, MUSICAL

lutes and viols had been strained. Harpsichords had long been preferred at the tertia minore. The Chorton of Praetorius, $a^1 422-5$, is practically the same pitch as the fork the possession of which has been attributed to Handel, $a^1 422-5$. It is a very fair mean between G. Silbermann's 18th-century Dresden pitch, $a^1 415$, and the organs of Renatus Harris, $a^1 428-7$. Stein tuned Mozart's piano to a fork $a^1 421-6$, and the Broadwood pianos used at the London Philharmonic Society in its first concerts (1813) were tuned to a fork $c^2 506-8$, which gives a mean tone $a^1 423-7$.

According to Schindler (Niederhessische Musik-Zeitung, 1855, Nos. 8 and 9), the report of the French Commission, 1859, the rise in pitch began at the Congress of Vienna in 1816, the military bands being the cause. With the improvements in wind instruments this continued, as a more brilliant effect was gained. In 1825 Weber's Euryanthe is recorded as having been played in Vienna at $a^1 437-5$, and in 1834 Kreutzer's Nachlager at $a^1 440$. The measurements are doubtful, but the upward tendency is clear. Scheibler, by his simple and accurate tonometer, has recorded pitches in Vienna about 1834 from $a^1 433-9$ to $a^1 440-2$. About that time, or it may be a few years earlier, Sir George Smart established a fork for the Philharmonic Society, $a^1 433-2$. Forks intended for this vibration number, stamped "Philharmonic," were sold as late as 1846. But about that year the performing pitch of the Society had reached $a^1 432-5$. Sir Michael Costa was the conductor 1846-1854, and from his acceptance of that high pitch the fork became known as Costa's, and its invention was attributed to him, though on insufficient grounds. In 1874 a further rise in the fork to $a^1 454$ was instigated by Sir Charles Halle. The British army is bound by the Majesty's Rules and Regulations to play at the Philharmonic pitch, and a fork tuned to $a^1 452-5$ in 1879 is preserved as the standard for the Military Training School at Kneiller Hall. But the Philharmonic Society adopted the Diapason Normal in 1886, and the military bands have not gone with it. In point of fact, they are gradually going higher, and the brass bands, which are so important in the North of England and in Wales, are not behind them.

It was the irrepressible upward tendency that caused the French government in 1829, acting with the advice of Halévy, Meyerbeer, Aubier, Ambroise Thomas and Rossini, to establish by law the Diapason Normal. Other countries have gradually followed. and, with few exceptions, the low pitch derived from the Diapason Normal may be said to prevail throughout the musical world. Great Britain has been the last to fall in, but the phenomenon of the rise in pitch introduced at Covent Garden Opera since 1876, is assured. The proprietors of Queen's Hall, London, did much for it when they undertook the alteration, at great expense, of their large concert organ, which had only just been erected. In 1896 the Philharmonic Society decided upon a performing pitch, ostensibly at 68° Fahr., of $a^1 430$; and in 1899 Messrs Broadwood made a successful effort to get this vibration number accepted by their competitors in Great Britain. The high pitch remains only where there are large concert organs not yet lowered, and with the military and brass bands.

The consideration of temperature as affecting the use of a standard pitch was not attended to when the French government issued its ordinance. The 15° Centigrade attached to the description of the standard fork in Paris was intended for the definition and verification of the fork only. The alteration of the fork due to heat is scarcely perceptible, but wind instruments, and particularly the organ, rise almost proportionately to the increase in temperature of the surrounding air, because sound travels at an enhanced rate as the temperature rises. The coefficient of this rise is equivalent to half a vibration (0-5) per degree Fahr. per second. D. J. Blakley (Essay on Musical Pitch, Catalogue of the Royal Military Exhibition, Chelsea, 1890), and Victor Mahillon (Catalogue descriptif et analytique du Musée, Bruxelles, troisième volume, appendix, 1900) have recorded their experience of wind instruments under changes of temperature. The French Commission, in establishing the Diapason Normal, should have chosen a temperature of 20° C.

There would then have been less disturbance owing to the breath of the players and heat of the theatres or concert-rooms. It would be a great advantage to get this higher grade generally adopted. It was proposed in the Stimm-Conferenz at Vienna in 1889, but not carried. Table I., showing orchestral pitches obtained in 1899, for the measurements of which the writer is responsible, prove how chimerical it is to hope for greater accuracy than is found between 435 and 440 vibrations a second for $a^1$, inasmuch as temperature must always be reckoned with.

Verified by A. J. Hipkins. But for Leipzig a comparison with the Gewandhaus Band may be sought. (A. J. H.)

PITCHBLENDE, or URANANITE, a mineral species consisting essentially of uranium oxide, of importance as a source of uranium and radium. It is a very heavy (specific gravity 9.0-9.3), compact mineral with a conchoidal to uneven fracture, and a brownish to velvet-black colour and pitchy lustre. Crystals are rare; they have the form of regular octahedra or less often of cubes. The hardness is 3½, and the streak is brown with a greenish tinge. The mineral has been known to occur at Joachimsthal in Bohemia since 1727, and it was early called pitchblende, because of its appearance; but its true nature was not recognized until 1789, when M. H. Klaproth's analysis of it resulted in the discovery of the element uranium. Analyses of material from different localities exhibit wide variations in chemical composition. In addition to uranium oxides, there are thorium, cerium (and lanthanum), yttrium and lead oxides, each varying in amount from a trace up to 10%. Calcium, iron, magnesium, manganese, silica, water, &c., are also present in small amounts. The amounts of uranium and uranoxide oxides (UO₂, 21-72; UO₃, 13-59%) also vary considerably. The mineral is often described as a uranate of uranil, lead, thorium and cerium; but in the least altered material from Branchville in Connecticut the uranous oxide predominates, whilst in altered specimens uranate oxide is in excess. In the closely allied mineral, thorlaniite, thorium predominates (ThO₂, 79; UO₃, 12%). Since the dioxide of uranium, thorium and cerium may be obtained artificially as cubic crystals, it seems probable that pitchblende consists of isomorphous mixtures of these dioxide, the uranous oxide being due to oxidation.

The radio-active properties of pitchblende are of special interest. The fact that this mineral is more strongly radio-active than metallic uranium led to the discovery of it in the elements radium, polonium and actinium. When pitchblende is ignited or dissolved in dilute sulphuric acid, a gas is evolved which consists largely of helium and argon; terrestrial helium was first recognized in this mineral.

The mineral occurs either as a primary constituent of granitic rocks or as one of secondary origin in metalliferous veins. Octahedral crystals ("cleveite" and "bröggerite") occur in the pegmatite veins of southern Norway, being occasionally found in the felspar quarries at Moss, Arndal and other places. Crystals are found under similar conditions at Middletown and Branchville in Connecticut, Llane county in Texas ("nivenite"), Mitchell county in North Carolina, Villeneuve in Quebec, and other American localities. Thoritane, found as water-worn cubes in the gem-gravels near Balangoda in Sabaragamuwa province, Ceylon, has also no doubt been derived from crystalline rocks. On the other hand, the mineral found in metalliferous veins, and to which the name pitchblende is more properly restricted, never occurs as crystals, but as compact masses rendered more or less impure by admixture of other minerals, the specific gravity being sometimes as low as 6-5; thorium, cerium, &c., are absent, and radium and helium are present in smaller amounts. This variety occurs with ores of silver, lead, copper, nickel, cobalt, bismuth, &c., at Joachimsthal, Przibram and Schneeberg in Saxony, Joachimsthal and Przibram in Bohemia, Rezsůna in Bihar Mountains in Hungary, Gilpin county in Colorado, St. Just, in Penwith, Redruth, Grampound Road and elsewhere in Cornwall.

Often associated with pitchblende, and resulting from its alteration, is an orange-yellow, amorphous, gum-like mineral called gummite, which is a hydrous uranic oxide with small amounts of lead, calcium, iron, &c. (L. J. S.)

PITCHER PLANTS, in botany, the name given to plants in which the leaves bear pitcher-like structures or are pitcher-like in form. The plant generally understood by this name is Nepenthes, a genus containing nearly sixty species, natives of tropical Asia, north Australia and (one only) of Madagascar. North Borneo is especially rich in species. They are shrubby plants climbing over surrounding vegetation by means of tendril-like prolongations of the midrib of the leaf beyond the leaf-tip.
PITCHER PLANTS

ridges, which are usually prolonged as teeth beyond the infolded margin. Above the mouth is the lid (operculum), which varies in size from a small narrow process to a large heart-shaped expansion. A study of the development of the pitcher, especially in the young pitchers of seedling plants, shows that the inflated portion is a development of the midrib of the leaf, while the wings, which are especially well represented in the terrestrial type of pitcher, represent the upper portion of the leaf-blade which has become separated from the lower portion by the tendril; the lid is regarded as representing two leaflets which have become fused. The short straight or curved process from the back of the pitcher behind the lid represents the organic apex of the leaf (A in fig. 1).

The size of the pitcher varies widely in the different species, from an inch to a foot or more in depth. The colour also varies considerably, even in different pitchers of the same individual, according to age, light exposure or soil conditions. It is uniformly green or more or less spotted, blotted or suffused with red or crimson, or sometimes, as in _N. sanguinea_ or _N. Edwardsiana_, largely or wholly of a rich scarlet or crimson colour. Insects are attracted to the mouth of the pitcher by a series of glands, yielding a sweet excretion, which occurs on the stem and also on the leaf from the base of the leaf-stalk to the lid and peristome. Embedded in the incurred margin of the rim which affords a very insecure foothold to insects, are a number of large glands excreting a sweet juice. The cavity of the pitcher is in some species lined throughout with a smooth glistening surface over which glands are uniformly distributed; these glands secrete a liquid which is found in the pitcher even in the young state while it is still hermatically closed by the lid. In other species the glands are confined to the lower portion of the cavity surface, while the upper part bears a smooth waxy secretion on which it is impossible, or at any rate extremely difficult, for insects to secure a foothold. This area is termed the "conducting" area, as distinguished from the lower or "detentive" gland-bearing area. It has been proved that the secretion contains a digestive ferment capable of rendering protein matter soluble. Insects, especially running insects, which have followed the track of honey glands upwards from the stem along the leaf, reach the mouth of the pitcher, and in their efforts to sip the attractive marginal glands fall over into the liquid. The smooth walls above the liquid afford no foothold, and they are drowned; their bodies are digested and the products of digestion are ultimately absorbed by the glands in the pitcher-wall. Thus _Nepenthes_ secures a supply of nitrogenous food from the animal world in a manner somewhat similar to that adopted by the British sundew, butterwort, and other insectivorous plants.

The side-saddle plant, _Suracenia_, native of the eastern United States, is also known as a pitcher-plant. There are about seven species, herbs with clusters of radical leaves some or all of which are more or less trumpet- or pitcher-shaped. The leaf has a broadly sheathing base succeeded by a short stalk bearing the pitcher, which represents a much enlarged midrib with a wing-like lamina. Above the rim of the pitcher is a broad flattened lid, which is also a laminar development. The surface of the leaf, especially the laminar wing, bears glands which in spring exude large glistening droplets of nectar. The lid and mouth of the pitcher are brighter coloured than the rest of the leaf, which varies from yellow-green to deep crimson in different species and in individuals according to exposure to sunlight and other conditions. This forms the attractive area, and the inner surface of the lid also bears numerous glands, as well as downward-pointing hairs, each with a delicately striated surface (fig. 2, A). Below it is the conducting surface (B) of glassy epidermal cells, with short downward-directed points, which facilitate the descent, but impede the ascent of an insect. Then come the glandular surface (C), which is formed of smooth polished epidermis with numerous glands that secrete the fluid contents of the pitcher, and finally the detentive surface (D), of which the cells are produced into long and strong bristles which point downwards and meet in the centre of the diminishing cavity so as to render escape impossible. The secretion wets an insect very rapidly, but, so far as is known, seems to be completely destitute of digestive power—indeed, rather to accelerate decomposition. The pitchers accumulate vast quantities of insects in the course of a season, and must thus abundantly manure the surrounding soil when they die. Moreover, the

feast is largely shared by unbidden guests. To speak of insects which feed upon the pitcher itself, some drop their eggs into the putrescent mass, where their larvae find abundant nourishment, while birds often silt open the pitchers with their beaks and devour the maggots in their turn.

Cephalotus follicularis, a native of south-west Australia, a small herbaceous plant, bears ordinary leaves close to the ground as well as pitchers. The latter somewhat resemble in general form those of Nepenthes. The lid is especially attractive to insects from its bright colour and honey secretion; three wings lead up to the mouth of the pitcher, on the inside of which a row of sharp spines points downwards, and below this a circular ridge (r, fig. 3) armed with papillae serves as a conducting area. A number of glands on the interior of the pitcher secrete a plentiful fluid which has digestive properties. Comparison with monstrous forms shows that the pitcher of Cephalotus arises by a calceolate pouching from the upper surface of the ordinary spathulate leaves, the lid here arising from the proximal side of the pitcher-ori.

**PITCHSTONE** (German *Pechstein*, from its resemblance to pitch). This is a glassy black rock having a resinous lustre and breaking with a hallow or conchoidal fracture. It differs from obsidian principally in its rather dull lustre, for obsidian is bright and vitreous in appearance; all pitchstones also contain a considerable quantity of water in combination amounting to from 5 to 10% of their weight or 10 to 20% of their volume. The majority of the rocks of this class occur as intrusive dikes or veins; they are glassy forms of quartz porphyry and other dike rocks. Their dull lustre may be connected with the great abundance of minute crystals and microlites which nearly always contain. These are visible only in microscopic sections, and their varied shapes make pitchstones very interesting to the microscopist. Although pitchstones are known which are of Devonian age (e.g. the glassy dacite of the Tay Bridge in Fife, Scotland, and the andesite-pitchstones of the Cheviot Hills), most of them are Tertiary or recent, as like all natural glasses they tend to crystallize or become devitrified in course of time. In some of the older pitchstones a larger part of the mass is changed to a felsitic substance, while only nodules or kernels of unaltered glass remain.

Some pitchstones are very acid rocks, containing 70 to 75% of silica, and have close chemical affinities to granites and rhyoliths. Others contain more alkalies and less silica, being apparently vitreous types of trachyte or kersantite; others have the composition of dacite and andesite. The pitchstones are highly basic rocks of the trachytic and rhyolitic series.

**PITHECANTHROPUS ERECTUS** (Erect Man), the name given by Dr Eugene Dubois, of the Dutch army medical service, to the imaginary creature which he constructed from fossilized bones found by him in Java. These fragments consisted of a thigh-bone, two teeth, and the upper part of a skull, and were unearthed in 1891-1892 on the left bank of the Bencawan River near Trinil. The skull appears to have been low and depressed with strong supraciliary ridges; the teeth are very large, and the femur is quite human. The teeth and skull were found together, the femur a few yards away a year afterwards. The discoverer, however, stated as his belief that the fragments were portions of the same skeleton and belonged to a creature half-way between man and the higher apes of the Pleistocene age. Much discussion followed the "find," and many authorities have given an opinion adverse to Dr Dubois's theory. The prevailing opinion is that the bones are human. They are not held to represent what has been called "the missing link," bridging over the gulf between man and the apes; but almost all authorities are agreed that they constitute a further link in the chain, bringing man nearer his Simian prototype. L. Manouvrier concludes that Homo erectus walked erect, was about almost as man was, and was a true precursor, possibly a direct ancestor, of man. He calls attention to the fact that the cranial capacity decreases in proportion to the antiquity of the human skulls found, and that the pithecanthropus skull has a capacity of from 900 to 1000 cc.—that is, "stands at the level of the smallest which have been occasionally found amongst the reputedly lowest savage peoples."

See Dubois, *Pithecanthropus erectus* (Batavia, 1894); a later paper read by Dr Dubois before the Berlin Anthropological Society was translated in the *Smithsonian Report* for 1895. Also a later paper read by Dr J. Cunningham before the Royal Dublin Society, January 23, 1895 (reported in *Nature*, February 28, 1895); O. C. Marsh,

PITHIVIERS, a town of north central France, capital of an arrondissement in the department of Loiret, 28 m. N.N.E. of Orleans, on the railway to Malherbes. Pop. (1906), 5676. The church of St Solomon, chiefly in the Renaissance style, and remains of the ancient ramparts are of interest. Statues have been erected of the mathematician Denis Poisson (d. 1840), and of the physician and agriculturist Duhamel de Monceau (d. 1782), natives of Pithiviers. The town is an agricultural market, and an important centre for the saffron of the region of Gâtinaria the cultivation of which, originally introduced by the Jews of Avignon in the 12th century was fostered by Louis XIV. The shrine of St Solomon in the 9th century and that of St Gregory, an Armenian bishop, in the 10th, formed the nucleus of the town; and the donjon built at the end of the 10th century for Héloïse, lady of Pithiviers, was one of the finest of the period.

PITHOM, one of the "treasure cities" stated to have been built for Pharaoh by the Hebrews in Goshen during the Oppression (Exod. i. 11). We have here the Hebrewized form of the Egyptian name, Horus of the City of the Great House. Horus (in Cretan, Patmos, capital of the 8th nome of Lower Egypt and situated in the Wadi Thumilat on the canal from the Nile to the Red Sea. Succoth (Egyptian Thuket) was identical with it or was in its immediate neighbourhood. The site, now Tell el-Maskhuta, has yielded several important monuments, including the best preserved of the trilingual stela of Darius which commemorated his work on the canal. The earliest name yet found is that of Rameses II. of the XIXth Dynasty, but in one case he has usurped earlier work, apparently of the XIIith Dynasty (a sphinx), and the city was evidently very ancient. Several of the monuments from Pithom have been removed to Ismailia on the Suez Canal.

See Ed. Naville, The Store City of Pithom and the route of the Exodus (London, 1885); W. M. F. Petrie, Texts, pt. i. (London, 1885); W. Golenischef. "Stèle de Darius" in Recueil de travaux relatif à la philologie et l'archéologie égyptiennes et assyriennes, xii. 99, and the article RAMESSES.

PITHOU, PIERRE (1539-1596), French lawyer and scholar, was born at Trowbridge, Wilts, on the 4th of January 1539. His taste for literature was early seen, and his father Pierre (1496-1536) cultivated it to the utmost. He was called to the Paris bar in 1560. On the outbreak of the second war of religion in 1566, Pithou, who was a Calvinist, withdrew to Sedan and afterwards to Basel, whence he returned to France on the publication of the edict of pacification. Soon afterwards he accompanied the duc de Montmorency on his embassy to England, returning shortly before the massacre of St Bartholomew, in which he narrowly escaped with his life. Next year he followed the example of Henry of Navarre by abjuring the Protestant faith. Henry, shortly after his own accession to the throne of France, recognized Pithou's talents and services by bestowing upon him various legal appointments. The most important work of his life was his co-operation in the production of the Satire Ménippée (1533), which did so much to damage the cause of the League; the harangue of the Steur d'Aubray is usually attributed to his pen. He died at Nogent-sur-Seine on the 1st of November 1596. His valuable library, specially rich in MSS., was for the most part transferred to what is now the Bibliothèque Nationale at Paris.

Pithou wrote a great number of legal and historical books, besides preparing editions of several ancient authors. His earliest publication was Adversarium subsecivorum lib. ii. (1565). Perhaps his edition of the Leges Visigothorum (1579) was his most valuable contribution to historical science; in the same line he edited the Capitula of Charlemagne, Louis the Pious, and Charles the Bald in 1588, and he also assisted his brother Francois in preparing an edition of the Corpus juris canonici (1587). His Libertés de l'église gallicane (1594) is reprinted in his Opera sacra juridica et oris miscellanea collecta (1600). In classical literature he was the first who made the world acquainted with the Fables of Phaedrus (1596); he also edited the Works of St. Jerome (1598-1599).

Three of Pithou's brothers acquired distinction as jurists: JEAN (1524-1602), author of Traité de police et du gouvernement des républiques, and, in collaboration with his twin brother NICOLAS (1524-1598), of Institution du mariage gallican and FRANCOIS (1534-1621), author of Glossarium ad libros capitularium. (1598), Traité des régulations et de l'interdit, &c. (1597).

PITIGLIANO, a town in Italy, province of Grosseto. Pop. (1901), 4416. It is the cathedral city of the bishopric named after the neighbouring town of Sovana, and possesses a 16th-century cathedral and a church of the 11th-15th centuries. Pitigliano was originally a gith of the countship of Sovana, which in 1293 came by marriage into the possession of the Orsini. In 1440 Sovana was taken by the Siennaese, but the terms of a peace concluded in 1447 the Orsini retained Pitigliano. See Orsini (nominated 1443) assuming the title of count of Pitigliano. The most famous of the line of counts was Niccolo III. (1442-1510), a celebrated condottiere. Under his successors Pitigliano became the scene of ceaseless family feuds culminating in assassinations. In 1562 the Medici of Florence seized part of their territories, and acquired the rest by exchange in 1580. The Orsini stronghold still stands in the town.

PITLOCHRY, a village of Perthshire, Scotland, 28 m. N.W. of Perth by the Highland railway. Pop. (1901), 1541. It lies on the left bank of the Tummel, a little below the confluence of that river and the Garry, 350 ft. above the sea. It is a favourite health resort and tourist centre. Among the immediate attractions are the pass of Killiecrankie, the falls of Tummel, the exquisite prospect called "Queen's View" (named after Queen Victoria) and Loch Tummel, 8 m. to the west. One m. S.E. of the village is the Black Spout, a waterfall of 80 ft. formed by the river Garry.

PITMAN, SIR ISAAC (1813-1897), English phonographer, was born at Trowbridge, Wilts, on the 4th of January 1813, and was educated at the local grammar school. He started in life as a clerk in a cloth factory, but in 1831 he was sent to the Normal College of the British and Foreign School Society in London. Between 1832 and 1839 he held masterships at Barton-on-Humber and Wotton-under-Edge, but he was dismissed by the authorities when he became a Swedenborgian, and from 1839 to 1843 he conducted a private school of his own at Bath. In 1829 he took up Samuel Taylor's system of shorthand, and from that time he became an enthusiast in developing the art of phonography. In 1837 he drew up a manual of Taylor's system and offered it to Samuel Bagster (1771-1852). The publisher did not accept the work, but suggested that Pitman should invent a new system (see SHORTHAND) of his own. The result was his Phonographic Soundhand (1837). Bagster's friendship and active help had been secured by Pitman's undertaking to verify the half-million references in the Comprehensive Bible, and he published the inventor's books at a cheap rate, thus helping to bring the system within the reach of all. Pitman devoted himself to perfecting phonography and propagating its use, and established at Bath a Phonetic Institute and a Phonetic Journal for this purpose; he printed in shorthand a number of standard works, and his book with the title Phonography (1840) went through many editions. He was an enthusiastic spelling reformer, and adopted a phonetic system which he tried to bring into general use. Pitman was twice married, his first wife dying in 1857, and his second, whom he married in 1861, surviving him. In 1894 he was knighted, and on the 22nd of January 1897 he died at Bath. Sir Isaac Pitman popularized shorthand at a time when the advent of the newspaper press and modern business methods were making it a matter of great importance. His system adapted itself readily to the needs of journalism, and its use revolutionized the work of reporting. It was a non-smoker, a vegetarian, and advocated temperance principles.

His Life was written by Alfred Baker (1898) and (1902) by his brother, Benn Pitman (1822-1911).
PITONI—PITT, WILLIAM 667

PITONI, GIUSEPPE OTTAVIO (1657–1743), Italian musical composer, was born at Rieti on the 18th of March 1657. He came to Rome as a boy and sang in the choir of SS Apostoli. Foggia gave him instructions in counterpoint, and he became maestro di Cappella, first at Terra di Rotondo and later (1673) at Assisi. In 1676 he went to Rieti, and in 1677 to Rome, where he held various appointments, dying on the 1st of Feb-

uary 1743 as maestro di Cappella at St Marco, where he was buried. Pitoni appears to have devoted himself exclusively to church music, and although he did not disdain the modern style with instrumental accompaniment, he is best known by his Masses and other works in the manner of Palestrina.

Several volumes of his autograph composition are in the Santini Library at Münster.

PITT, THOMAS (1653–1726), British East India merchant and politician, usually called “Diamond Pitt,” was born at Blandford, Dorset, on the 5th of July 1653. In early life he went to India, and from his headquarters at Balasore he made trading journeys into Persia and soon became prominent among those who were carrying on business in opposition to the East India Company. Twice he was arrested by order of the company, the second time being when he reached London in 1683, but after litigation he obtained for some years in England he returned to India in 1699 to undertake business. He then entered the East India Company took him into its service in 1695, and in 1697 he became president of Fort St George, or Madras.

Pitt was now very zealous in defending the interests of his employers against the new East India Company, and in protecting their settlements from the attacks of the natives; in directing the commercial undertakings of the company he also appears to have been very successful. Soon, however, he had a serious quarrel with William Fraser, a member of his council, and consequently he was relieved of his office in 1709, although he was afterwards consulted by the company on matters of importance. During his residence in India Pitt bought for about £20,000 the fine diamond which was named after him; in 1717 he sold this to the regent of France, Philip duke of Orleans, for £80,000 or, according to another account, for £135,000.

It is now the property of the French government. During his former stay in England Pitt had bought a good deal of property, including the manor of Old Sarum, and for a short time he had represented this borough in parliament. After his final return from India in 1710 he added to his properties and again became member of parliament for Old Sarum. He died at Swallowfield, Reading, on the 28th of April 1726. His eldest son, Robert, was the father of William Pitt, earl of Chatham (q.v.); and of Thomas Pitt (d. 1761), whose son became the first Lord Camelford; his second son, Thomas Pitt (c. 1688–1729), having married Frances (d. 1772), daughter of Robert Ridgeway, 4th earl of Londonderry (d. 1714), was himself created earl of Londonderry in 1726.

PITT, WILLIAM (1750–1806), English statesman, the second son of William Pitt, earl of Chatham, and of Lady Hester Grenville, daughter of Hester, Countess Temple, was born at Hayes, near Bromley, Kent, on the 28th of May 1759. The child inherited a name which, at the time of his birth, was the most illustrious in the civilized world, and was pronounced by every Englishman with pride, and by every enemy of England with mingled admiration and terror. During the first year of his life every month had its illuminations and bonfires, and every wind brought some messenger charged with joyful tidings and hostile standards. In Westphalia the English infantry won a great battle which arrested the armies of Louis XV. near Conques; at Ticonderoga in Canada the opposing French and English forces to the number of forty thousand engaged. On the 10th of July 1759 the British fleet defeated one of the French under Tilly, and Pitt's father, as is well known, was created earl of Chatham.

The pleasure with which William's parents observed the rapid development of his intellectual powers was alloyed by apprehensions about his health. He shot up alarmingly fast; he was often ill, and always weak; and it was feared that it would be impossible to rear a stripling so tall, so slender, and so feeble. Pitt was a brilliant, precocious child; it was said of him that he could read by the time he was two years old. His health improved, and he became a noted subject for the medical profession.

Pitt entered a school in London and was sent to Eton at the age of thirteen. He was a good scholar, and was noted for his precocity. He was a member of the Blue Stockings, a club of young men who met to discuss political and philosophical questions. Pitt was one of the most brilliant members, and it was said that he was a faithful servant of the Crown, on the other an ambitious and unprincipled conspirator. At length the king, who had been missing, reappeared, resumes his power, and rewards the faithful defender of his rights. A reader who should judge only by internal evidence would have no hesitation in pronouncing that the play was written by some Pittite poetaster at the time of the rejoicings for the recovery of George III. in 1789.

The wealth with which William's parents observed the rapid development of his intellectual powers was alloyed by apprehensions about his health. He shot up alarmingly fast; he was often ill, and always weak; and it was feared that it would be impossible to rear a stripling so tall, so slender, and so feeble. Pitt was a brilliant, precocious child; it was said of him that he could read by the time he was two years old. His health improved, and he became a noted subject for the medical profession.

Pitt was a member of the Blue Stockings, a club of young men who met to discuss political and philosophical questions. Pitt was one of the most brilliant members, and it was said that he was a faithful servant of the Crown, on the other an ambitious and unprincipled conspirator. At length the king, who had been missing, reappeared, resumes his power, and rewards the faithful defender of his rights. A reader who should judge only by internal evidence would have no hesitation in pronouncing that the play was written by some Pittite poetaster at the time of the rejoicings for the recovery of George III. in 1789.
PITT, WILLIAM

studies, though often interrupted by illness, were prosecuted with extraordinary success. He was sent, towards the close of the year 1773, to Pembroke Hall, in the university of Cambridge. The governor to whom the direction of William's academic life was confided was a bachelor of arts named Pretyman, who had been senior wrangler in the preceding year, and, who though not a man of prepossessing appearance or brilliant parts, was eminently acute and laborious, a sound scholar, and an excellent geometrician. A close and lasting friendship sprang up between the pair. The disciple was able, before he completed his twenty-eighth year, to make his preceptor bishop of Lincoln and dean of St Paul's; and the preceptor showed his gratitude by writing a life of the disciple, which enjoys the distinction of being the worst biographical work of its size in the world. Pitt, till he graduated, had scarcely one acquaintance, attended chapel regularly morning and evening, dined ever day in hall, and never went to a single evening party. At seventeen he was admitted, after the fashion of those times, by right of birth, without any examination, to the degree of master of arts. But he continued during some years to reside at college, and to apply himself vigorously, under Pretyman's direction, to the studies of the place, while mixing freely in the best academic society.

The stock of learning which Pitt laid in during this part of his life was certainly very extraordinary. The work in which he took the greatest delight was Newton's Principia. His liking for mathematics, indeed, amounted to a passion, which, in the opinion of his instructors, themselves distinguished mathematicians, required to be checked rather than encouraged. Nor was the youth's proficiency in classical learning less remarkable. In one respect, indeed, he appeared to disadvantage when compared with even ex-ex-rate and third-rate men from public schools. He had never, while under Wilson's care, been in the habit of composing in the ancient languages; and he therefore never acquired the knack of versification. It would have been utterly out of his power to produce such charming elegiac lines as those in which Wellesley bade farewell to Eton, or such Virginian hexameters as those in which Canning described the pilgrimage to Mecca. But it may be doubted whether any scholar has ever, at twenty, had a more solid and profound knowledge of the two great tongues of the old civilized world. He had set his heart on being intimately acquainted with all the extant poetry of Greece, and was not satisfied till he had mastered Lycophron's Cassandra.

To modern literature Pitt paid comparatively little attention. He knew no living language except French; and French he knew very imperfectly. With a few of the best English writers he was intimate, particularly with Shakespeare and Milton. The debate in Pandemonium was, as it well deserved to be, one of his favourite passages; and his early friends used to talk, long after his death, of the just emphasis and the melodious cadence with which they had heard him recite the incomparable speech of Belial. He had indeed been carefully trained from infancy in the art of managing his voice, a voice naturally clear and deep-toned. At a later period the wits of Brookes's, irritated by observing, night after night, how powerfully Pitt's sonorous elocution fascinated the rows of country gentlemen, reproached him with having been "taught by his dad on a stool."

His education, indeed, was well adapted to form a great parliamentary speaker. The classical studies of Pitt had the effect of enriching his English vocabulary, and of making him wonderfully expert in the art of constructing correct English sentences. His practice was to look over a page or two of a Greek or Latin author, to make himself master of the meaning, and then to read the passage straight forward into his own language. This practice, begun under his first teacher Wilson, was continued under Pretyman. Of all the remains of antiquity, the orations were those on which he bestowed the most minute examination. His favourite employment was to compare hamangues on opposite sides of the same question, to analyse them, and to observe which of the arguments of the first speaker were refuted by the second, which were evaded, and which were left untouched. Nor was it only in books that he at this time studied the art of parliamentary fencing. When he was at home he had frequent opportunities of hearing important debates at Westminster; and he heard them, not only with interest and enjoyment, but with close scientific attention. On one of these occasions Pitt, a youth whose abilities were as yet known only to his own family and to a small knot of college friends, was introduced on the steps of the throne in the House of Lords to Fox, his senior by eleven years, who was already the greatest debater, and one of the greatest orators, that had appeared in England. Fox used afterwards to relate that, as the discussion proceeded, Pitt repeatedly turned to him, and said, "But surely, Mr Fox, that might be met thus," or "Yes; but he lays himself open to this retort."

What the particular criticisms were Fox had forgotten; but he said that he was much struck at the time by the precocity of a lad who, through the whole sitting, seemed to be thinking only how all the speeches on both sides could be answered.

He had not quite completed his nineteenth year when, on the 7th of April 1778, he attended his father to Westminster. A great debate was expected. It was known that France had recognized the independence of the United States. The duke of Richmond was about to declare his opinion that all thought of subjugating those states ought to be relinquished. Chatham had early maintained that the resistance of the colonies to the mother country was justifiable. But he conceived, very erroneously, that on the day on which their independence should be acknowledged the greatness of England would be at an end. Though sinking under the weight of years and infirmities, he determined, in spite of the entreaties of his family, to be in his place. His son supported him to a seat. The excitement and exertion were too much for the old man. In the very act of addressing the peers, he fell back in convulsions. A few weeks later his corpse was borne, with gloomy pomp, from the Painted Chamber to the Abbey. The favourite child and namesake of the deceased statesman followed the coffin as chief mourner, and saw it deposited in the transept where his own was destined to lie. His elder brother, now earl of Chatham, had means sufficient, and barely sufficient, to support the dignity of the peerage. The other members of the family were much less well off. William had little more than £300 a year.

It was necessary for him to follow a profession. He had already begun to "eat his terms." In the spring of 1780 he came of age. He then quitied Cambridge, was called to the bar, took chambers in Lincoln's Inn, and joined the western circuit. In the autumn of that year a general election took place; and he offered himself as a candidate for the university; but he was at the bottom of the poll. He was, however, at the request of an hereditary friend, the duke of Rutland, brought into parliament by Sir James Lowther for the borough of Appleby.

The dangers of the country were at that time such as might well have disturbed even a constant mind. Army after army had been sent in vain against the rebellious colonists of North America. Meanwhile the house of Bourbon, humbled to the dust a few years before by the genius and vigour of Chatham, had seized the opportunity of revenge. France and Spain had united against England, and had recently been joined by Holland. The command of the Mediterranean had been for a time lost. The British flag had been scarcely able to maintain itself in the British Channel. The northern powers professed neutrality; but their neutrality had a menacing aspect. In the East, Hyder Ali had descended on the Carnatic, had destroyed the little army of Baillie, and had spread terror even to the ramparts of Fort St George. The discontents of Ireland threatened nothing less than civil war. In England the authority of Lord North's government had sunk to the
lowest point. The king and the House of Commons were alike unpopular. The cry for parliamentary reform was scarce- less loud and vehement than afterwards in 1830.

The Opposition consisted of two parties which had once been hostile to each other, but at this conjuncture seemed to act together with cordiality. The larger of these parties consisted of the great body of the Whig aristocracy, headed by Charles, marquess of Rockingham. In the House of Commons the adherents of Rockingham were led by Fox, whose dissipated habits and ruined fortunes were the talk of the whole town, but whose commanding genius, and whose sweet, generous and affectionate disposition, extorted the admiration and love of those who most lamented the errors of his private life. Burke, superior to Fox in largeness of comprehension, in extent of knowledge, and in splendour of imagination, but less skilled in that kind of logic and in that kind of rhetoric which convince and persuade great assemblies, was willing to be the lieutenant of a young chief who might have been his son. A smaller section of the Opposition was composed of the old followers of Chatham. At their head was William, earl of Shelburne, distinguished both as a statesman and as a lover of science and letters. With him were leagued Lord Camden, who had formerly held the Great Seal, and whose integrity, ability and constitutional knowledge commanded the public respect; Barré, an eloquent and acrimonious declamer; and Dunning, who had long held the first place at the English bar. It was to this party that Pitt was naturally attracted.

On the 26th of February 1781 he made his first speech in favour of Burke's plan of economical reform. Fox stood up at the same moment, but instantly gave way. The lofty yet animated deportment of the young member, his perfect self-possession, the readiness with which he replied to the orators who had preceded him, the silver tones of his voice, the perfect structure of his unpremeditated sentences, astonished and delighted his hearers. Burke, moved even to tears, exclaimed, "It is not a chip of the old block; it is the old block itself." "Pitt will be one of the first men in parliament," said a member of the Opposition to Fox. "He is so already," answered Fox, in whose nature envy had no place. Soon after this debate Pitt's name was put up by Fox at Brookes's Club. On two subsequent occasions during that session Pitt addressed the house, and on both fully sustained the reputation which he had acquired on his first appearance. In the summer, after the prorogation, he again went the western circuit, held several briefs, and acquitted himself in such a manner that he was highly complimented by Buller from the bench, and by Dunning at the bar.

On the 27th of November the parliament reassembled. Only forty-eight hours before had arrived tidings of the surrender of Corunvalis and his army. In the debate on the report of the address Pitt spoke with even more energy and brilliancy than on any former occasion. He was warmly applauded by his allies; but it was remarked that no person on his own side of the house was so loud in eulogy as Henry Dundas, the lord advocate of Scotland, who spoke from the ministerial ranks. From that night dates his connexion with Pitt, a connexion which soon became a close intimacy, and which lasted till it was dissolved by death. About a fortnight later Pitt spoke in the committee of supply on the army estimates. Symptoms of dissension had begun to appear on the treasury bench. Lord George Germaine, the secretary of state who was especially charged with the direction of the war in America, had held language not easily to be reconciled with declarations made by the first lord of the treasury. Pitt noticed the discrepancy with much force and keenness. Lord George and Lord North began to whisper together; and Welbore Ellis, an ancient placeman who had been drawn, salary almost every quarter since the days of Henry Pelham, bent down between them to put in a word. Such interruptions sometimes discompose veteran speakers. Pitt stopped, and, looking at the group, said with admirable readiness, "I shall wait till Nestor has composed the dispute between Agamemnon and Achilles." After several defeats, or victories hardly to be distinguished from defeats, the ministry resigned. The king, reluctantly and ungraciously, consented to accept Rockingham as first minister. Fox and Shelburne became secretaries of state. Lord John Cavendish, one of the most upright and honourable of men, was made chancellor of the exchequer. Thurlow, whose abilities and force of character had made him the dictator of the House of Lords, continued to hold the Great Seal. To Pitt was offered, through Shelburne, the vice-treasurership of Ireland, one of the easiest and most highly paid places in the gift of the Crown; but the offer was without hesitation declined. The young statesman had resolved to accept no post which did not entitle him to a seat in the cabinet; and a few days later (March 1782) he announced that resolution in the House of Commons.

Pitt gave a general support to the administration of Rockingham, but omitted, in the meantime, no opportunity of courting that ultra-Whig party which the persecution of Wilkes and the Misdemeanor Wilson had called into existence, and which the disastrous events of the war, and the triumph of republican principles in America, had made formidable both in numbers and in temper. He supported a motion for shortening the duration of parliaments. He made a motion for a committee to examine into the state of the representation, and, in the speech (May 7, 1782) by which that motion was introduced, avowed himself the enemy of the close boroughs, the strongholds of that corruption to which he attributed all the calamities of the nation, and which, as he phrased it in one of those exact and sonorous sentences of which he had a boundless command, had grown with the growth of England and strengthened with her strength, but had not diminished with her diminution or decayed with her decay. On this occasion he was supported by Fox. The motion was lost by only twenty votes in a house of more than three hundred members. The Reformers never again had so good a division till the year 1831.

The new administration was strong in abilities, and was more popular than any administration which had held office since the first year of George III., but was hated by the king, hesitatingly supported by the parliament, and torn by internal dissensions. It was all that Rockingham could do to keep the peace in his cabinet; and before the cabinet had existed three months Rockingham died. In an instant all was confusion. The adherents of the deceased statesman looked on the duke of Portland as their chief. The king placed Shelburne at the head of the treasury. Fox, Lord John Cavendish, and Burke immediately resigned their offices; and the new prime minister was left to constitute a government out of very defective materials. It was necessary to find some member of the House of Commons who could confront the great orators of the Opposition; and Pitt alone had the eloquence and the courage which were required. He was offered the great place of chancellor of the exchequer and he accepted it (July 1782). He had scarcely completed his twenty-third year.

The parliament was speedily prorogued. During the recess a negotiation for peace which had been commenced under Rockingham was brought to a successful termination. England acknowledged the independence of her revolted colonies; and she ceded to her European enemies some places in the Mediterranean and in the Gulf of Mexico. But the terms which she obtained were quite as advantageous and honourable as the events of the war entitled her to expect, or as she was likely to obtain by persevering in a contest against immense odds. There is not the slightest reason to believe that Fox, if he had remained in office, would have hesitated one moment about concluding a treaty on such conditions. Unhappily Fox was, at this crisis, hurried by his passions into an error which made his genius and his virtues, during a long course of years, almost useless to his country. He saw that the great body of the House of Commons was divided into three parties—his own, that of North, and that of Shelburne; that none of those three parties was large enough to stand alone; that, therefore, unless two of them united there must be a miserably feeble administration,
or, more probably, a rapid succession of miserably feeble administrations, and this at a time when a strong government was essential to the prosperity and respectability of the nation. It was then necessary and right that there should be a coalition. To every possible coalition there were objections. But of all possible coalitions that to which there were the fewest objections was undoubtedly a coalition between Shelburne and Fox. It would have been generally applauded by the followers of both.

It might have been made without any sacrifice of public principle on the part of either. Unhappily, recent bickerings had left in the mind of Fox a profound dislike and distrust of Shelburne. Pitt attempted to mediate, and was authorized to invite Fox to return to the service of the Crown. "Is Lord Shelburne," said Fox, "to remain prime minister?" Pitt answered in the affirmative. "It is impossible that I can act under him," said Fox. "Then negotiation is at an end," said Pitt; "for I cannot betray him." Thus the two statesmen parted. They were never again in a private room together. As Fox and his friends would not treat with Shelburne, nothing remained to them but to treat with North. That fatal coalition which is emphatically called "The Coalition" was formed. Not three-quarters of a year had elapsed since Fox and Burke had threatened North with impeachment, and had described him night after night as the most arbitrary, the most corrupt, and the most incapable of ministers. They now allied themselves with him for the purpose of driving from office a statesman with whom they cannot be said to have differed as to any important question. Nor had they even the prudence and the patience to wait for some occasion on which they might, without inconsistency, have combined with their old enemies in opposition to the government. That nothing might be wanting to the scandal, the great orator who had, during seven years, thumped against the war determined to join with the authors of that war in passing a vote of censure on the peace.

The parliament met before Christmas 1782. But it was not till January 1783 that the preliminary treaties were signed. On the 17th of February they were taken into consideration by the House of Commons. There had been, during some days, floating rumours that Fox and North had coalesced; and the debate indicated but too clearly that those rumours were unfounded. Pitt was suffering from indisposition—he did not rise till his own strength and that of his helpers were exhausted; and he was consequently less successful than on any former occasion. His admirers owned that his speech was feeble and petulant. He so far forgot himself as to advise Sheridan to continue himself, and to go to the House of Lords. Then his former sarcasm gave Sheridan an opportunity of retorting with great felicity. "After what I have seen and heard to-night," he said, "I really feel strongly tempted to venture on a competition with so great an artist as Ben Jonson, and to bring on the stage a second Angry Boy." On a division, the address proposed by the supporters of the government was rejected by a majority of sixteen. But Pitt was not a man to be disheartened by a single failure, or to be put down by the most lively repartee. When, a few days later, the Opposition proposed a resolution directly censuring the treaties, he spoke with an eloquence, energy and dignity which raised his fame and popularity higher than ever. To the coalition of Fox and North he alluded in language which drew forth tumultuous applause from his followers. "If," he said, "this illomened and unnatural marriage be not yet consummated, I know of a just and lawful impediment; and, in the name of the public weal, I forbid the banns." The ministers were again left in a minority, and Shelburne consequently tendered his resignation (March 31, 1783). It was accepted; but the king struggled long and hard before he submitted to the terms dictated by Fox, whose faults he detested, and whose high spirit and powerful intellect he detested still more. The first place at the board of treasury was repeatedly offered to Pitt; but the offer, though tempting, was steadfastly declined. The king, bitterly complaining of Pitt's faint-heartedness, tried to break the coalition. Every art of seduction was practised on North, but in vain. During several weeks the country remained without a government. It was not till all devices had failed, and till the aspect of the House of Commons became threatening, that the king gave way. The duke of Portland was declared first lord of the treasury. Thurlow was dismissed. Fox and North became secretaries of state, with power ostensibly equal. But Fox was the real prime minister. The year was far advanced before the new arrangements were completed; and nothing very important was done during the remainder of the session. Pitt, now seated on the Opposition Bench, brought the question of parliamentary reform a second time (May 7, 1783) under the consideration of the Commons. He proposed to add to the house at once a hundred county members and several members for metropolitan districts, and to enact that every borough of which an election committee should report that the majority of voters appeared to be corrupt should lose the franchise. The motion was rejected by 263 votes to 149.

After the prorogation Pitt visited the Continent for the first and last time. His travelling companions was one of his most intimate, friends, William Wilberforce. That was the time of Anglomania in France; and at Paris the son of the great Chatham was absolutely hunted by men of letters and women of fashion, and forced, much against his will, into political disputation. One remarkable saying which dropped from him during this tour has been preserved. A French gentleman expressed some surprise at the immense influence which Fox, a man of pleasure, ruined by the dice-box and the turf, exercised over the English nation. "You have not," said Pitt, "been under the wand of the magician."

In November 1783 the parliament met again. The government had irresistible strength in the House of Commons, and it seemed to be scarcely less strong in the House of Lords, but was, in truth, surrounded on every side by dangers. The king was impatiently waiting for the moment at which he could emancipate himself from a yoke which galled him so severely that he had more than once seriously thought of retiring to Hanover; and the king was scarcely more eager for a change than the nation. Fox and North had committed a fatal error. They ought to have known that coalitions between parties which have long been hostile can succeed only when the wish for coalition pervades the lower ranks of both. At the beginning of 1783 North had been the recognized head of the old Tory party, which, though for a moment prostrated by the disastrous issue of the American war, was still a great power in the state. Fox had, on the other hand, been the idol of the Whigs, and of one side of Protestant dissenters. The coalition at once alienated the most zealous Tories and the most zealous Whigs from Fox. Two great multitudes were at once left without any head, and both at once turned their eyes on Pitt. One party saw in him the only man who could rescue the king; the other saw in him the only man who could purify the parliament. He was supported on one side by Archbishop Markham, the preacher of divine right, and by Jenkinson, the captain of the practioner band of the king's friends; on the other side by Jebb and Priestley, Sawbridgeway and Cartwright, Jack Wilkes and Horne Tooke. On the benches of the House of Commons, however, the ranks of the ministerial majority were unbroken; and that any statesman would venture to brave such a majority was thought impossible. No prince of the Hanoverian line had ever, under any provocation, ventured to appeal from the representative body to the constituent body. The ministers, therefore, notwithstanding the sullen looks and muttered words of displeasure with which their suggestions were received in the closet, notwithstanding the roar of obloquy which was rising louder and louder every day from every corner of the island, thought themselves secure. Such was their confidence in their strength that, as soon as the parliament had met, they brought forward a singularly bold and original plan for the government of the British territories in India. What was proposed in Fox's India bill was that the whole authority which till that time had been exercised over those territories by the East India Company should be transferred to seven commissioners, who were to be
named by parliament, and were not to be removable at the pleasure of the Crown. Earl Fitzwilliam, the most intimate personal friend of Fox, was to be chairman of this board, and the eldest son of North was to be one of the members.

As soon as the outlines of the scheme were known all the hatred which the coalition had excited burst forth with an astounding explosion. Burke, who, whether right or wrong in the conclusions to which he came, had at least the merit of looking at the subject in the right point of view, vainly reminded his hearers of that mighty population whose daily rice might depend on a vote of the British parliament. He spoke with even more than his wonted power of thought and language, about the desolation of Rohilkund, about the spoliation of Benares, about the evil policy which had suffered the tanks of the Carnatic to go to ruin; but he could scarcely obtain a hearing. The contending parties, to their shame it must be said, would listen to none but English topics. Out of doors the cry against the ministry was almost universal. Town and country were united. Corporations exclaimed against the violation of the charter of the greatest corporation in the realm. Tories and democrats joined in pronouncing the proposed board an unconstitutional body. It was to consist of Fox's nominees. The effect of his Bill was to give, not to the Crown, but to him personally, whether in office or in opposition, an enormous power, a patronage sufficient to counterbalance the patronage of the treasury and of the admiralty, and to decide the elections for fifty boroughs.

He knew, it was said, that he was hateful alike to king and people; and he had devised a plan which would make him independent of both. Some nicknamed him Cromwell, and some Carlo Khan. Wilberforce, with his usual felicity of expression, and with very unusual bitterness of feeling, described the scheme as the genuine offspring of the coalition, as marked with the features of both its parents, the corruption of one and the violence of the other. In spite of all opposition, however, the Bill was read a second time by vote, and rapidly passed, and was sent up to the Lords. To the general astonishment, when the second reading was moved in the upper house, the Opposition proposed an adjournment, and carried it by eighty-seven votes to seventy-nine. The cause of this strange turn of fortune was soon known. Pitt's cousin Earl Temple, had been in the royal closet, and had there been authorized to let it be known that his majesty would consider all who voted for the bill as his enemies. The ignominious commission was performed, and instantly a troop of lords of the bedchamber, of bishops who wished to be translated, and of Scotch peers who wished to be re-elected, made haste to change sides. On a later day the Lords rejected the bill. Fox and North were immediately directed to send their seals to the palace by their under-secretaries; and Pitt was appointed first lord of the treasury and chancellor of the exchequer (December 1783).

The general opinion was that there would be an immediate dissolution. But Pitt wisely determined to give the public feeling time to gather strength. On this point he differed from his kinsman Temple. The consequence was that Temple, who had been appointed one of the secretaries of state, resigned his office forty-eight hours after he had accepted it, and thus relieved the new government from a great load of unpopularity; for all men of sense and honour, however strong might be their dislike of the India Bill, disapproved of the manner in which that bill had been thrown out. The fame of the young prime minister preserved its whiteness. He could declare with perfect truth that, if unconstitutional machinations had been employed, he had been no party to them.

He was, however, surrounded by difficulties and dangers. In the House of Lords, indeed, he had a majority; nor could any orator of the Opposition in that assembly be considered as a match for Thurlow, who was now again chancellor, or for Camden, who cordially supported the son of his old friend Chatham. But in the other house there was not a single eminent speaker among the official men who sat round Pitt. His most useful assistant was Dundas, who, though he had not eloquence, had sense, knowledge, readiness and boldness. On the opposite benches was a powerful majority, led by Fox, who was supported by Burke, North and Sheridan. The heart of the young minister, stout as it was, almost died within him. But, whatever his internal emotions might be, his language and deportment indicated nothing but unconquerable firmness and haughty confidence in his own powers. His contest against the House of Commons lasted from the 17th of December 1783 to the 5th of March 1784. In sixteen divisions the Opposition triumphed. Again and again the king was requested to dismiss his ministers; but he was determined to go to Germany rather than yield. Pitt's resolution never wavered. The cry of the nation in his favour became vehement and almost furious. Addressing assuring him of public support came up daily from every part of the kingdom. The freedom of the city of London was presented to him in a gold box. He was sumptuously feasted in Grocers' Hall; and the shopkeepers of the Strand and Fleet Street illuminated their houses in honour. These things could not but produce an effect within the walls of parliament. The ranks of the majority began to waver; a few passed over to the enemy; some skulked away; many were for capitating while it was still possible to capitulate with the honours of war. Negotiations were opened with the view of forming an administration on a wide basis, but they had scarcely been opened when they were closed. The Opposition demanded, as a preliminary article of the treaty, that Pitt should resign the treasury; and with this demand Pitt steadfastly refused to comply. While the contest was raging, the clerkship of the Pells, a sinecure place for life, worth three thousand a year, and tenable with a seat in the House of Commons, became vacant. The appointment was with the chancellor of the exchequer; nobody doubted that he would appoint himself, and nobody could have blamed him if he had done so; for such sinecure offices had always been defended on the ground that they enabled a few men of eminent abilities and opinions to live a life in which all men of public profession, and who did not wish to devote themselves to the service of the state. Pitt, in spite of the remonstrances of his friends, gave the Pells to his father's old adherent, Colonel Barré, a man distinguished by talent and eloquence, but poor and afflicted with blindness. By this arrangement a pension which the Rockingham administration had granted to Barré was saved to the public. Pitt had his reward. No minister was ever more rancorously libelled; but even when he was known to be overwhelmed with debt, when millions were passing through his hands, when the wealthiest magnates of the realm were soliciting him for marquises and garters, his bitterest enemies did not dare to accuse him of touching unlawful gain.

At length the hard-fought fight ended. A final remonstrance, drawn up by Burke with admirable skill, was carried on the 8th of March by a single vote in a full house. The supply had been voted in the Mutiny Bill had been passed; and the parliament was dissolved. The popular constituent bodies all over the country were in general enthusiastic on the side of the new government. A hundred and sixty of the supporters of the coalition lost their seats. The first lord of the treasury himself came in at the head of the poll for the university of Cambridge. Wilberforce was elected knight of the great shire of York, in opposition to the whole influence of the Fitzwilliams, Cavendishes, Dundases and SAVILES. In the midst of such triumphs Pitt completed his twenty-fifth year. He was now the greatest subject that England had seen during many generations. He domineered absolutely over the cabinet, and was the favourite at once of the sovereign, of the parliament and of the nation. His father had never been so powerful, nor Walpole, nor Marlborough.

Pitt's first administration (1783-1801) lasted seventeen years. That long period is divided by a strong marked line into two almost exactly equal parts. The first part, which ended and the second began in the autumn of 1792. Throughout both parts Pitt displayed in the highest degree the talents of a parliamentary leader. During the first
part he was fortunate and in many respects a skilful administrator. With the difficulties which he had to encounter during the second part he was altogether incapable of contending, but his eloquence and his perfect mastery of the tactics of the House of Commons concealed his incapacity from the multitude.

The eight years which followed the general election of 1784 were as tranquil and prosperous as any eight years in the whole history of England. Her trade increased. Her manufactures flourished. Her exchequer was full to overflowing. Very idle apprehensions were generally entertained that the public debt, though much less than a third of the debt which we now bear with ease, would be found too heavy for the strength of the nation. But Pitt succeeded in persuading first himself and then the whole nation, his opponents included, that a new sinking fund, which, so far as it differed from former sinking funds, differed for the worse, would, by virtue of some mysterious power of propagation belonging to money, put into the pocket of the public creditor great sums not taken out of the pocket of the tax-payer. The minister was almost universally extolled as the greatest of financiers. Meanwhile both the branches of the house of Bourbon found that England was as formidable an antagonist as ever. The crown was a great deal more solicitous for reducing Holland to vassalage. But England interposed, and France receded. Spain interrupted by violence the trade of the English merchants with the regions near the Oregon. But England armed, and Spain receded. Within the island there was profound tranquillity. The king was, for the first time, popular. From the day on which Pitt was placed at the head of affairs there was an end of secret influence. Any attempt to undermine him at court, any mutinous movement among his followers in the House of Commons, was certain to be at once put down. He had only to tender his resignation and he could dictate his own terms. For he, and he alone, stood between the king and the coalition. The nation loudly applauded the king for having the wisdom to repose entire confidence in so excellent a minister. His people heartily prayed that he might long reign over them; and they prayed the more heartily because his virtues were set off to the best advantage by the vices and follies of the prince of Wales, who lived in close intimacy with the chiefs of the Opposition. The prince was too much indebted to the king for carrying the day, and was sensible enough of the danger which attended the policy of the Opposition. His queen, she was become insane. The Opposition, eager for office, committed the great indiscretion of asserting that the heir apparent had, by the fundamental laws of England, a right to be regent with the full powers of royalty. Pitt, on the other hand, maintained it to be the constitutional doctrine that when a sovereign is, by reason of infancy, disease or absence, incapable of exercising the regal functions, it belongs to the estates of the realm to determine who shall be the viceregent, and with what portion of the executive authority such viceregent shall be entrusted. A long and violent contest followed, in which Pitt was supported by the great body of the people with as much enthusiasm as during the first months of his administration. Tories with one voice applauded him for defending the sick-bed of a virtuous and unhappy sovereign against a disloyal faction and an undutiful son. Not a few Whigs applauded him for asserting the authority of parliament and the principles of the Revolution, in opposition to a doctrine which seemed to have for its foundation the theory of indefeasible hereditary right. The middle class, always jealous on the side of decency and the domestic virtues, looked forward with dismay to a reign resembling that of Charles II. That the prince of Wales must be regent nobody ventured to deny. But he and his friends were so unpopular that Pitt could, with general approbation, propose to limit the powers of the regent by restrictions to which it would have been impossible to subject a prince beloved and trusted by the country. Some interested men, fully expecting a change of administration, went over to the Opposition. But the majority, purified by these desertions, closed its ranks, and presented a more firm array than ever to the enemy. In every division Pitt was victorious. When at length, after a stormy interregnum of three months, it was announced, on the very eve of the inauguration of the regent, that the king was himself again, the nation was wild with delight. Pitt with difficulty escaped from the tumultuous kindness of an innumerable multitude which insisted on drawing his coach from St Paul's Churchyard to Downing Street. This was the moment at which his fame and fortune may be said to have reached the zenith. His influence in the closet was as great as that of Carr or Villiers had been. His dominion over the parliament was more absolute than that of Walpole or Pelham had been. He was at the same time as high in the favour of the populace as ever Wilkes or Sacheverell had been. But now the tide was on the turn. Only ten days after the triumphant procession to St Paul's, the states-general of France, after an interval of a hundred and seventy-four years, met at Versailles.

The nature of the great Revolution which followed was long very imperfectly understood in England. Burke saw much further than any of his contemporaries; but whatever his sagacity described was refracted and discoloured by his passions and his imagination. More than three years elapsed before the principles of the English administration underwent any material change. Nothing could as yet be milder or more strictly constitutional than the minister's domestic policy. Not a single act indicating an arbitrary temper or a jealousy of the people could be imputed to him. In office, Pitt had redeemed the pledges which he had, at his entrance into public life, given to the supporters of parliamentary reform. He had, in 1785, brought forward a judicious plan for the representative system, and had prevailed on the king, not only to refrain from talking against that plan, but to recommend it to the houses in a speech from the throne. This attempt failed; but there can be little doubt that, if the French Revolution had not produced a violent reaction of public feeling, Pitt would have performed, with little difficulty and no danger, that great work which, at a later period, Lord Grey could accomplish only by means which for a time loosened the very foundations of the commonwealth. When the atrocities of the slave trade were first brought under the consideration of parliament no abolitionist was more zealous than Pitt. A humane bill, which was passed, and the memory of which is only carried by the eloquence and determined spirit of Pitt, in spite of the opposition of some of his own colleagues. In 1791 he cordially concurred with Fox in maintaining the sound constitutional doctrine that an impeachment is not terminated by a dissolution. In the course of the same year the two great rivals contended side by side in a far more important cause. They are fairly entitled to divide the high honour of having added to the statute-book the indomitable law which places the liberty of the press under the protection of juries. On one occasion, and one alone, Pitt, during the first half of his long administration, acted in a manner unworthy of an enlightened Whig. In the debate on the Test Act he stooped to gratify the master whom he served, the university which he represented, and the great body of clergymen and country gentlemen on whose support he rested, by talking, with little heartiness indeed, and with no asperity, the language of a Tory. With this single exception, his conduct from the end of 1783 to the middle of 1792 was that of an honest friend of civil and religious liberty.

Nor did anything, during that period, indicate that he loved war, or harboured any malevolent feeling against any neighbouring nation. Those French writers who have represented him as a Hannibal sworn in childhood by his father to bear eternal hatred to France, as having, by mysterious intrigues and lavish bribes, instigated the leading Jacobins to commit those excesses which dishonoured the Revolution, as having been the real

1 The speech with which the king opened the session of 1785 concluded with an assurance that his majesty would heartily concur in every measure which could tend to secure the true principles of the constitution. These words were at the time understood to refer to Pitt's Reform Bill.
author of the first coalition, know nothing of his character or of his history. So far was he from being a deadly enemy to France that his laudable attempts to bring about a closer connexion with that country by means of a wise and liberal treaty of commerce brought on him the severe censure of the Opposition. He was told in the House of Commons that he was a degenerate son, and that his partiality for the hereditary foes of our island was enough to make his great father's bones stir under the pavement of the Abbey.

And this man, whose name, if he had been so fortunate as to die in 1792, would have been associated with peace, with freedom, with philanthropy, with temperate reform, with mild and constitutional administration, lived to associate his name with arbitrary government, with harsh laws harshly executed, with alien bills, with gagging bills, with suspensions of the habeas corpus Act, with cruel punishments inflicted on some political agitators, with unjustifiable prosecutions instigated against others and with the most costly and most sanguinary wars of modern times. He lived to be held up to obloquy as the stern oppressor of England and the indefatigable disturber of Europe. Poets, contrasting his earlier with his later years, likened him sometimes to the apostle who kissed in order to betray, and sometimes to the evil angels who kept not their first estate. By the French press and the French tribune every crime that disgraced and every calamity that afflicted France was ascribed to the monster Pitt and his guineas. While the Jacobins were dominant it was he who had corrupted the Girondes, who had raised Lyons and Bordeaux against the Convention, who had subdued Paris to assassinate Lapelletier, and Cecilia Regnault to assassinate Robespierre. When the Thermidorian reaction came, all the atrocities of the Reign of Terror were laid to his charge. Collof D'Herois and Fouquier Tinville had been his pensioners. It was he who had hired the murderers of September, who had dictated the pamphlets of Marat and the carmagnoles of Barère, who had paid Lebon to deluge Arras with blood and Carrier to choke the Loire with corpses. The truth is that he liked neither war nor arbitrary government. He was a lover of peace and freedom, driven, by a stress against which it was hardly possible for any will or any intellect to struggle, out of the course to which his inclinations pointed, and for which his abilities and acquirements fitted him, and forced into a policy repugnant to his feelings and unsuited to his talents.

Between the spring of 1789 and the close of 1792 the public mind of England underwent a great change. If the change of Pitt's sentiments attracted peculiar notice, it was not because he changed more than his neighbours, for in fact his changed views were less than those of them. It was because his position was far more conspicuous than theirs, because he was, till Bonaparte appeared, the individual who filled the greatest space in the eyes of the inhabitants of the civilized world. During a short time the nation, and Pitt as one of the nation, looked with interest and approbation on the French Revolution. But soon vast confiscations, the violent sweeping away of ancient institutions, the domination of clubs, the barbarities of mobs maddened by famine and hatred, produced a reaction. The court, the nobility, the gentry, the clergy, the manufacturers, the merchants, in short nineteen-twentieths of those who had good roots over their heads and good coats on their backs, became eager intolerant Antis Jacobins. This feeling was at least as strong among the minister's adversaries as among his supporters. Fox in vain attempted to restrain his followers. All his genius, all his vast personal influence, could not prevent them from rising up against him in general mutiny. Burke set the example of revolt; and Burke was in no long time joined by Portland, Spencer, Fitzwilliam, Loughborough, Carlisle, Malmesbury, Windham, Elliot. In the House of Commons the followers of the great Whig statesman and orator diminished from about a hundred and sixty to fifty. In the House of Lords he had but ten or twelve adherents left. There can be no doubt that there would have been a similar mutiny on the ministerial benches if Pitt had obstinately resisted the general wish. Pressed at once by his master and by his colleagues, by old friends and by old opponents, he abandoned, slowly and reluctantly, the policy which was dear to his heart. He laboured hard to avert the European war. When the European war broke out he still flattered himself that it would not be necessary for this country to take either side. In the spring of 1792 he congratulated the parliament on the prospect of long and profound peace, and proved his sincerity by proposing large remissions of taxation. Down to the end of that year he continued to cherish the hope that England might be able to preserve neutrality. But the passions which raged on both sides of the Channel were not to be restrained. The republicans who ruled France were inflamed by a fanaticism resembling that of the Mussulmans, who, with the Koran in one hand and the sword in the other, went forth conquering and converting, eastward to the Bay of Bengal, and westward to the Pillars of Hercules. The higher and middle classes of England were animated by zeal not less fiery than that of the crusaders who raised the cry of Jesus vallat at Clermont. The impulse which drove the two nations to a collision was not to be arrested by the abilities or by the authority of any single man. As Pitt was in front of his fellows, and towered high above them, he seemed to lead them. But in fact he was violently pushed on by them, and, had he held back but a little more than he did, would have been thrust out of their way or trampled under their feet.

He yielded to the current; and from that day his misfortunes began. The truth is that there were only two consistent courses before him. Since he did not choose to oppose Pitt's War Policy, he should have taken the advice of Burke, and should have availed himself of that feeling to the full extent. If it was impossible to preserve peace, he should have adopted the only policy which should lead to victory. He should have proclaimed a holy war for religion, morality, property, order, public law, and should have thus opposed to the Jacobins an energy equal to their own. Unhappily he tried to find a middle path; and he found one which united all that was worst in both extremes. He went to war; but he could not understand the peculiar character of that war. He was obstinately blind to the plain fact that he was contending against a state which was also a sect, and that a new quarrel between England and France was of quite a different kind from the old quarrels about colonies in America and fortresses in the Netherlands. It was pitiable to hear him, year after year, proving to an admiring audience that the wicked republic was exhausted, that she could not hold out, that her credit was gone, that her assignats were not worth more than the paper of which they were made—as if credit was a fact, and not a question of time. As if the two nations, as if Alboin could not turn Italy into a desert till he had negotiated a loan at 5%, as if the exchequer bills of Attila had been at par. It was impossible that a man who so completely mistook the nature of a contest could carry on that contest successfully. Great as Pitt's abilities were, his military administration was that of a driver. In such an emergency, and with such means, such a statesman as Richelieu, as Louvois, as Chatham, as Wellesley, would have created in a few months one of the finest armies in the world, and would soon have discovered and brought forward generals worthy to command such an army. Germany might have been saved by another Blenheim; Flanders recovered by another Ramillies; another Potier might have delivered the Royalist and Catholic provinces of France from a yoke which they abhorred, and might have spread terror even to the barriers of Paris. But the fact is that, after eight years of war, after a vast destruction of life, after an expenditure of wealth far exceeding the expenditure of the American War, of the Seven Years' War, of the War of the Austrian Succession and of the War of the Spanish Succession united, the English army under Pitt was the laughing-stock of all Europe. It could not boast of one single brilliant exploit. It had never shown itself on the Continent but to be beaten, chased, forced to re-embark or forced to capitulate. To take some sugar island in the West Indies, to scatter some mob of half-naked Irish peasants—such were the most splendid victories.
won by the British troops under Pitt’s auspices. The English navy no mismanagement could ruin. But during a long period whatever mismanagement could do was done. The earl of Chatham, without a single qualification for high public trust, was made, by fraternal partiality, first lord of the admiralty, and was kept in that great post during two years of a war in which the very existence of the state depended on the efficiency of the fleet. Fortunately he was succeeded by George, Earl Spencer, one of those chiefs of the Whig party who, in the great schism caused by the French Revolution, had followed Burke. Lord Spencer, though inferior to many of his colleagues as an orator, was decidedly the best administrator among them. To him it was owing that a long and gloomy succession of days of fasting, and most emphatically of humiliation, was interrupted, twice in the short space of eleven months, by days of thanksgiving for great victories.

It may seem paradoxical to say that the incapacity which Pitt showed in all that related to the conduct of the war is, in some sense, the most decisive proof that he was a man of very extraordinary abilities. Yet this is the simple truth. While his schemes were sound, while his predictions were fulfilled, while the coalitions which he had laboured to form were falling to pieces, while the expeditions which he had sent forth at enormous cost were ending in rout and disgrace, while the enemy against whom he was freely contending was subjugating Flanders and Brabant, the electorate of Mainz and the electorate of Trèves, Holland, Piedmont, Liguria, Lombardy, his authority over the House of Commons was constantly becoming more and more absolute. There was his empire. There were his victories—his Lodi and his Arcola, his Rivoli and his Marengo. Of the great party which had contended against him during the first eight years of his administration more than one-half now marched under his standard, with his old competitor the duke of Portland at their head; and the rest had, after many vain struggles, quitted the field in despair. Session followed session with scarcely a single division. In the eventful year 1799 the largest minority that could be mustered against the government was twenty-five.

In Pitt’s domestic policy there was at this time assuredly no want of vigour. While he offered to French Jacobinism a resistance so feeble that it only encouraged the evil which he wished to suppress, he put down English Jacobinism with a strong hand. The Habeas Corpus Act was repeatedly suspended. Public meetings were placed under severe restraints. The government obtained from parliament power to send out of the country aliens who were suspected of evil designs; and that power was not suffered to be idle. Writers who propounded doctrines adverse to monarchy and aristocracy were proscribed and punished without mercy. The old laws of Scotland against sedition, laws which were considered by Englishmen as barbarous, and which a succession of governments had suffered to rust, were now furnished up and sharpened anew. Men of cultivated minds and polished manners were, for offences which at Westminster would have been treated as mere misdemeanours, sent to herd with felons at Botany Bay. Some reformers, whose opinions were extravagant, and whose language was intemperate, but who had never dreamed of subverting the government by physical force, were indicted for high treason; and were saved from the gallows only by the righteous verdicts of juries.

One part only of Pitt’s conduct during the last eight years of the 18th century deserves high praise. He was the first English minister who formed great designs for the benefit of Ireland. Had he been able to do all that he wished, it is probable that a wise and liberal policy would have averted the rebellion of 1798. But the difficulties which he encountered were great, perhaps insurmountable; and the Roman Catholics were, rather by his misfortune than by his fault, thrown into the hands of Jacobins. There was a third great rising of the Irishry against the Englishry, a rising not less formidable than the risings of 1641 and 1689. The Englishry remained victorious; and it was necessary for Pitt, as it had been necessary for Oliver Cromwell and William of Orange before him, to consider how the victory should be used. He determined to make Ireland one kingdom with England, and, at the same time, to relieve the Roman Catholic laity from civil disabilities, and to grant a public maintenance to the Roman Catholic clergy. Had he been able to carry these noble designs into effect the union would have been a union indeed. But Pitt could execute only one-half of what he had projected. He succeeded in obtaining the consent of the parliaments of both kingdoms to the union; but that reconciliation of races and sects without which the union could exist only in name was not accomplished. The king imagined that his coronation oath bound him to refuse his assent to any bill for relieving Roman Catholics from civil disabilities. Dundas tried to explain the matter, but was told to keep his Scotch metaphysics to himself. Pitt and Pitt’s ablest colleagues resigned their offices (March 14, 1801).

It was necessary that the king should make a new arrangement. But by this time his anger and distress had brought back the malady which had, many years before, incapacitated him for the discharge of his functions. He actually assembled his family, read the coronation oath to them, and told them that, if he broke it, the crown would immediately pass to the house of Savoy. It was not until after an interregnum of several weeks that he regained the full use of his small faculties, and that a ministry after his own heart was at length formed. In an age pre-eminently fruitful of parliamentary talents, a cabinet was formed containing hardly a single man who in parliamentary talents could be considered as even of the second rate. Henry Addington was at the head of the treasury. He had been, indeed, an hereditary friend of Pitt, and had, by Pitt’s influence been placed, while still a young man, in the chair of the House of Commons. He was universally admitted to have been the best Speaker that had sat in that chair since the retirement of Onslow. But nature had not bestowed on him very vigorous faculties; and the highly respectable situation which he long occupied with honour had rather unfitted than fitted him for the discharge of his new duties. Nevertheless, during many months, his power seemed to stand firm. The nation was put into high good humour by a peace with France. The enthusiasm with which the country rose and fell into the war had spent itself. Jacobinism was no longer formidable. Everywhere there was a strong reaction against what was called the atheistical and anarchical philosophy of the 18th century. Bonaparte, now first consul, was busied in constructing out of the ruins of old institutions a new ecclesiastical establishment and a new order of knighthood. The treaty of Amiens was therefore hailed by the great body of the English people with extravagant joy. The popularity of the minister was for the moment immense. His want of parliamentary ability was, as yet, of little consequence; for he had scarcely any adversary to encounter. The old Opposition, delighted by the peace, regarded him with favour. A new Opposition had indeed been formed by some of the late ministers, and was led by Grenville in the House of Lords and by Windham in the House of Commons. But the new Opposition could scarcely muster ten votes, and was regarded with no favour by the country.

On Pitt the ministers relied as on their firmest support. He had not, like some of his colleagues, retired in anger. He had expressed the greatest respect for the conscientious scruple which had taken possession of the royal mind; and he had promised his successors all the help in his power. But it was hardly possible that this union should be durable. Pitt, conscious of superior powers, imagined that the place which he had quitted was now occupied by a mere puppet which he had set up, which he was to govern while he suffered it to remain, and which he was to fling aside as soon as he wished to resume his old position. Nor was it long before he began to pine for the power which he had relinquished. Addington, on the other hand, was by no means inclined to descend from his high position. He took his elevation quite seriously, attributed it.
to his own merit, and considered himself as one of the great triumvirates of English statesmen, as worthy to make a third with Pitt and Fox. Meanwhile Pitt's most intimate friends exerted themselves to effect a change of ministry. His favourite disciple, George Canning, was indefatigable. He spoke; he wrote; he intrigued; he tried to induce a large number of the supporters of the government to sign a round robin desiring a change; he made game of Addington and of Addington's relations in a succession of lively pasquinades. The minister's partisans retorted with equal acrimony, if not with equal vivacity.

Pitt could keep out of the fray only by keeping out of politics altogether; and this it soon became impossible for him to do. The treaty of Amiens had scarcely been signed when the restless ambition and the insupportable insolence of the First Consul convinced the great body of the English people that the peace so eagerly welcomed was only a precarious armistice. As it became clearer and clearer that a war for the dignity, the independence, the very existence of the nation was at hand, men looked with increasing uneasiness on the weak and languid cabinet which would have to contend against an enemy who united more than the power of Louis the Great to more than the genius of Frederick the Great. They imagined that Pitt was the only statesman who could cope with Bonaparte. This feeling was nowhere stronger than among Addington's own colleagues. The pressure put on him was so strong that he could not help yielding to it. His first proposition was that some insignificant nobleman should be first lord of the treasury and nominal head of the administration, and that the real power should be divided between Pitt and himself, who were to be secretaries of state. Pitt, as might have been expected, refused even to discuss such a scheme, and talked of it with bitter mirth. "Which secretaryship was offered to you?" his friend Wilberforce asked. "Really," said Pitt, "I had not the curiosity to inquire." Addington was frightened into bidding higher. He offered to resign the treasury to Pitt on condition that there should be no extensive change in the government. But Pitt would listen to no such terms. Then came a dispute such as often arises after negotiations orally conducted, even when the negotiators are men of strict honour. Pitt gave one account of what had passed; Addington gave another; and, though the discrepancies were not such as necessarily implied any intentional violation of truth on either side, both were greatly exasperated.

Meanwhile the quarrel with the First Consul had to come to a crisis. On the 16th of May 1803 the king sent a message calling on the House of Commons to support him in withstanding the ambitious and encroaching policy of France; and on the 22nd the house took the message into consideration.

Pitt had long been living many months in retirement. There had been a general election since he had spoken in parliament, and there were two hundred members who had never heard him. It was known that on this occasion he would be in his place, and curiosity was wound up to the highest point. Unfortunately, the shorthand writers were, in consequence of some mistake, shut out on that day from the gallery, so that the newspapers contained only a very meagre report of the proceedings. But several accounts of what passed are extant; and of those accounts the most interesting is contained in an unpublished letter written by a very young member, John William Ward, afterwards earl of Dudley. When Pitt rose he was received with loud cheering. At every pause in his speech there was a burst of applause. The peroration is said to have been one of the most animated and magnificent ever heard in parliament.

"Pitt's speech," Fox wrote a few days later, "was admired very much, and very justly. I think it was the best he ever made in that style." The debate was adjourned; and on the second night Fox replied to it in an oration which, as the most zealous Pittites were forced to acknowledge, left the palm of eloquence doubtful. Addington made a pitiable appearance between the two great rivals; and it was observed that Pitt, while exhorting the Commons to stand resolutely by the executive government against France, said not a word indicating esteem or friendship for the prime minister.

War was speedily declared. The First Consul threatened to invade England at the head of the conquerors of Belgium and Italy, and formed a great camp near the Straits of Dover. On the other side of those straits the whole British population was ready to rise up as one man in defence of the soil. In the spring of 1804 it became evident that the weakest of ministries would have to defend itself against the strangest of Oppositions, an Opposition made up of three Oppositions, each of which would, separately, have been formidable from ability, and which, when united, were also formidable from number. It was necessary to give way; the ministry was dissolved, and the task of performing a government was entrusted (May 1804) to Pitt. Pitt was of opinion that there was now an opportunity, such as had never before offered itself, and such as might not offer itself again, of uniting in the public service, on honourable terms, all the eminent talents of the kingdom.

The treasury he reserved for himself; and to Fox he proposed to assign a share of power little inferior to his own. The plan was excellent; but the king would not hear of it. Dull, obstinate, unforgiving, and at that time half mad, he positively refused to admit Fox into his service. In an evil hour Pitt yielded. All that was left was to construct a government out of the wreck of Addington's feeble administration. The small circle of Pitt's personal retainers furnished him with a very few useful assistants, particularly Dundas (who had been created Viscount Melville), Lord Harrowby and Canning.

Such was the inauspicious manner in which Pitt entered on his second administration (May 12, 1804). The whole history of that administration was of a piece with the commencement. Almost every month brought some new disaster or disgrace. To the war with France was soon added a war with Spain. The opponents of the ministry were numerous, able and active. His most useful coadjutors he soon lost. Sickness deprived him of the help of Lord Harrowby. It was discovered that Lord Melville had been guilty of highly culpable laxity in transactions relating to public money. He was censured by the House of Commons, driven from office, ejected from the privy council and impeached of high crimes and misdemeanours. The blow fell heavy on Pitt. His difficulties compelled him to resort to various expedients. At one time Addington was persuaded to accept office with a peerage; but he brought no additional strength to the government. While he remained in place he was jealous and pugnacious; and he soon retired again. At another time Pitt renewed his efforts to overcome his minister's aversion to Fox; and it was rumoured that the king's obstinacy was gradually giving way. But, meanwhile, it was impossible for the minister to conceal from the public eye the decay of his health and the constant anxiety which gnawed at his heart. All who passed him in the park, all who had interviews with him in Downing Street, saw misery written in his face. The peculiar look which he wore during the last months of his life was often pathetically described by Wilberforce, who used to call it the Austerlitz look.

Still the vigour of Pitt's intellectual faculties and the intrepid haughtiness of his spirit remained unaltered. He had staked everything on a great venture. He had succeeded in forming another mighty coalition against the French ascendency. The united forces of Austria, Russia and England might, he hoped, oppose an insurmountable barrier to the ambition of the common enemy. But the genius and energy of Napoleon prevailed. The general who had so lately been a prisoner of war at Kehl for Germany, the Russian troops were slowly coming up from Poland, he, with rapidity unprecedented in modern war, moved a hundred thousand men from the shores of the ocean to the Black Forest, and compelled a great Austrian army to surrender at Ulm. To the faintest rumours of this calamity Pitt would give no credit. He was irritated by the alarms of those around him. "Do not believe a word of it," he said; "it is all a fiction." The next day he received a Dutch newspaper containing the
PITT, WILLIAM

The news of the battle of Trafalgar arrived four days later, and seemed for a moment to revive him. Forty-eight hours after that most glorious and most mournful of victories had been announced to the country came the Lord Mayor's Day; and Pitt dined at Guildhall. His popularity had declined. But on this occasion the multitude, greatly excited by the recent tidings, welcomed him enthusiastically, took off his horses in Cheapside, and drew his carriage up King Street. When his health was drunk, he returned thanks in two or three of those stately sentences of which he had a boundless command. Several of those who heard him laid up his words in their hearts; for they were the last words that he ever uttered in public: "Let us hope that England, having saved herself by her energy, may save Europe by her example."

This was but a momentary rally. Austerlitz soon completed what Ulm had begun. Early in December Pitt had retired to Bath, in the hope that he might there gather strength for the approaching session. While he was languishing there on his sofa arrived the news that a decisive battle had been fought and lost in Moravia, that the coalition was dissolved, that the Continent was at the feet of France. He sank down under the blow. Ten days later he was so emaciated that his most intimate friends hardly knew him. He came up from Bath by slow journeys, and on the 11th of January 1806 reached his villa at Putney. Parliament was to meet on the 21st. On the 20th was to be the parliamentary dinner at the house of the first lord of the treasury in Downing Street; and the cards were already issued. But the days of the great minister were numbered. On the day on which he was carried into his bedroom at Putney, the Marquess Wellesley, whom he had long loved, whom he had sent to govern India, and whose administration had been eminently able, energetic and successful, arrived in London after an absence of eight years. The friends saw each other once more. There was an affectionate meeting and a last parting. That it was a last parting Pitt did not seem to be aware. He fancied himself to be recovering, talked on various subjects cheerfully and with an unclouded mind, and pronounced a warm and discerning eulogium on the marquis's brother Arthur. "I never," he said, "met with any military man with whom it was so satisfactory to converse." The excitement and exertion of this interview were too much for the sick man. He fainted away; and Lord Wellesley left the house convinced that the close was fast approaching.

And now members of parliament were fast coming up to London. The chiefs of the Opposition met for the purpose of considering the course to be taken on the first day of the session. It was easy to guess what would be the language of the king's speech, and of the address which would be moved in answer to that speech. An amendment condemning the policy of the government had been prepared, and was to have been proposed in the House of Commons by Lord Henry Petty (afterwards 3rd marquess of Lansdowne). He was unwilling, however, to come forward as the accuser of one who was incapable of defending himself. Lord Grenville, who had been informed of Pitt's state by Lord Wellesley, and had been deeply affected by it, earnestly recommended forbearance; and Fox, with characteristic generosity and good nature, gave his voice against attacking his now helpless rival. "Sunt lacrymae rerum," he said, "et mentem mortalia tangit." On the first day therefore there was no debate. It was rumoured that evening that Pitt was better. But on the following morning his physicians pronounced that there were no hopes. It was asserted in many after-dinner speeches, Grub Street elegies and academic prize poems and prize declarations that the great minister died exclaiming, "Oh my country!" This is a fable, but it is true that the last words which he uttered, while he knew what he said, were broken exclamations about the alarming state of public affairs. He ceased to breathe on the morning of the 23rd of January 1806, the twenty-fifth anniversary of the day on which he first took his seat in parliament.

It was moved in the House of Commons that Pitt should be honoured with a public funeral and a monument. The motion was opposed by Fox in a speech which deserves to be studied as a model of good taste and good feeling. The task was the most invidious that ever an orator undertook; but it was performed with a humanity and delicacy which were warmly acknowledged by the mourning friends of him who was gone. The motion was carried by 285 votes to 89. The 22nd of February was fixed for the funeral. The corpse, having lain in state during two days in the Painted Chamber, was borne with great pomp to the northern transept of the Abbey. A splendid train of princes, nobles, bishops and privy councillors followed. The grave of Pitt had been made near to the spot where his great father may, near also to the spot where his great rival was soon to lie. Wilberforce, who carried the banner before the hearse, described the awful ceremony with deep feeling. As the coffin descended into the earth, he said, the eagle face of Chatham from above seemed to look down with consternation into the dark house which was receiving all that remained of so much power and glory.

Pitt was emphatically the man of parliamentary government, the type of his class, the minion, the child, the spoiled child, of the House of Commons. He was a distinguished member of the House of Commons at twenty-one. The ability which he had displayed in the House of Commons made him the most powerful subject in Europe before he was twenty-five. It was when the House of Commons was to be convinced and persuaded that he put forth all his powers. Of those powers we must form our estimate chiefly from tradition; for, of all the eminent speakers of that age, Pitt has suffered most from the reporters. Even while he was still living, critics remarked that his eloquence could not be preserved, that he must be heard to be appreciated. They more than once applied to him the sentence in which Tacitus describes the fate of a senator whose rhetoric was admired in the Augustan age: "Hateri canorum illud et profuens cum ipso simul exitantium est." There is, however, abundant evidence that nature had bestowed on Pitt the talents of a great orator; and those talents had been developed in a very peculiar manner, first by his education, and secondly by the high official position to which he rose early, and in which he passed the greater part of his public life.

At his first appearance in parliament he showed himself superior to all his contemporaries in command of language. He could pour forth a long succession of round and stately periods, without premeditation, without ever pausing for a word, without ever repeating a word, in a voice of silver clearness, and with a pronunciation so articulate that not a letter was slurred over. He had less amplitude of mind and less richness of imagination than Burke, less ingenuity than Windham, less wit than Sheridan, less perfect mastery of dialectical fence and less of that highest sort of eloquence which consists of reason and passion fused together than Fox. Yet the almost unanimous judgment of those who were in the habit of listening to that remarkable race of men placed Pitt, as a speaker, above Burke, above Windham, above Sheridan and not below Fox. His declamation was copious, polished and splendid. In power of sarcasm he was probably not surpassed by any speaker, ancient or modern; and of this formidable weapon he made merciless use. In two parts of the oratorical art which are of the highest value to a minister of state he was singularly expert. No man knew better how to be luminous or how to be obscure. When he wished to be understood, he never failed to make himself understood. Nothing was out of place; nothing was forgotten; minute details, dates, sums of money, were all faithfully preserved in his memory. On the other hand, when he did not wish to be explicit—and no man who is at the head of affairs always wishes to be explicit—he had a marvellous power
of saying nothing in language which left on his audience the impression that he had said a great deal.

The effect of oratory will always to a great extent depend on the character of the orator. There perhaps were never two speakers whose eloquence had more of what may be called the race, more of the flavour imparted by moral qualities, than Fox and Pitt. The speeches of Fox owe a great part of their charm to that warmth and softness of heart, that sympathy with human suffering, that admiration for everything great and beautiful, and that hatred of cruelty and injustice, which interest and delight us even in the most defective reports. No person, on the other hand, could hear Pitt without perceiving him to be a man of high, intrepid and commanding spirit, proudly conscious of his own rectitude and of his own intellectual superiority, incapable of the low vices of fear and envy, but too prone to feel and to show disdain. Pride, indeed, pervaded the whole man, was written in the harsh, rigid lines of his face, was marked by the way in which he walked, in which he sat, in which he stood, and above all, in which he bowed. Such pride, of course, inflicted many wounds. But his pride, though it made him bitterly disliked by individuals, inspired the great body of his followers in parliament and throughout the country with respect and confidence. It was that of the magnanimous man so finely described by Aristotle in the *Ethics*, of the man who thinks himself worthy of great things, being in truth worthy. It was closely connected, too, with an ambition which had no mixture of low cupidity. There was something noble in the cynical disdain with which the mighty minister scattered riches and titles to right and left among those who valued them, while he spurred them out of his way. Poor himself, he was surrounded by friends on whom he had bestowed three thousand, six thousand, ten thousand a year. Plain Mister himself, he had made more lords than any three ministers that had preceded him. The garter, for which the first dukes in the kingdom were contending, was repeatedly offered to him, and offered was vaunted.

The correctness of his private life added much to the dignity of his public character. In the relations of son, brother, uncle, master, friend, his conduct was exemplary. In the small circle of his intimate associates he was amiable, affectionate, even playful. He indulged, indeed, somewhat too freely in wine, which he had early been directed to take as a medicine, and which use had made a necessary of life to him. But it was very seldom that any indication of undue excess could be detected in his tones or gestures; and, in truth, two bottles of port were little more to him than two dishes of tea. He had, when he was first introduced into the clubs of St James's Street, shewn a strong sense for play; but he had the prudence and the resolution to stop before this taste had acquired the strength of habit. From the passion which generally exercises the most tyrannical dominion over the young he possessed an immunity, which is probably to be ascribed partly to his temperament and partly to his situation. His constitution was very feeble; he was very shy; and he was very busy. The strictness of his morals furnished such auxiliaries as Peter Pindar and Captain Morris with an inexhaustible theme for merriment of no very delicate kind. But the great body of the middle class of Englishmen could not see the joke. They warmly praised the young statesman for commanding his passions, and for covering his frailties, if he had frailties, with decorous obscurity.

The memory of Pitt has been assailed, times innumerable, often justly, often unjustly; but it has suffered much less from his assailants than from his eulogists. For, during many years, his name was the rallying cry of a class of men with whom, at one of those terrible conjunctions which confound all ordinary distinctions, he was accidentally and temporally connected, but to whom, on almost all great questions of principle, he was diametrically opposed. The haters of parliamentary reform called themselves Pittites, not in order to remember that Pitt made three motions for parliamentary reform, and that, though he thought that such a reform could not safely be made while the passions excited by the French Revolution were raging, he never uttered a word indicating that he should not be prepared at a more convenient season to bring the question forward a fourth time. The toast of Protestant ascendency was drunk on Pitt's birthday by a set of Pittites who could not but be aware that Pitt had resigned his office because he could not carry Catholic emancipation. The defenders of the Test Act called themselves Pittites, though they could not be ignorant that Pitt had laid before George III. unanswerable reasons for abolishing the Test Act. The enemies of free trade called themselves Pittites, though Pitt was far more deeply imbued with the doctrines of Adam Smith than either Fox or Grey. The very negro-drivers invoked the name of Pitt, whose eloquence was never more conspicuously displayed than when he spoke of the wrongs of the negro. This mythical Pitt, who resembles the genuine Pitt as little as the Charlemagne of Ariosto resembles the Charlemagne of Eginhard, has had his day. History will vindicate the real man from calumni disguised under the semblance of adulation, and will exhibit him as what he was—"a minister of great talents, honest intentions and liberal opinions, pre-eminently qualified, intellectually and morally, for the part of a parliamentary leader, and capable of administering with prudence and moderation the government of a prosperous and tranquil country, but unequal to surprising and terrible emergencies, and liable in such emergencies to err grievously, both on the side of weakness and on the side of violence." (M.)

**PITTA**, in ornithology, from the Telugu *pitta*, meaning a small bird, latinized by Vieillot in 1816 (*Analyse*, p. 42) as the name of a genus, and since adopted by English ornithologists as the general name for a group of birds, called by the French *Brèves*, and remarkable for their great beauty. 1 For a long while the

---

1 In ornithology the word is first found as part of the native name, "Pomunkey pitta," of a bird, given in 1713 by Petiver, in the "manitissa" to Ray's *Synopsis* (p. 195), on the authority of Buckley (see *Ornithology*). This bird is the *Pitta Bengelinsis* of modern ornithologists, and is said by Jerdon (*Birds of India*, i. 509) now to bear the Telugu name of *Pono-inki*. 

*Pitta elegant*, male and female.
family was gradually admitted. Their position was partly determined by A. H. Garrod, who, having obtained examples for dissection, in a communication to the Zoological Society of London, printed in its *Proceedings* for 1876, proved (pp. 512, 513) that the Pittidae belonged to that section of Passerine birds which he named Mesomyody, since their syrinx, like that of the Tyrannidae (see *King-Bird*), has its muscles attached to the middle of its half-rings, instead of to their extremities as in the higher Passerines or Acromyody. They are now placed as a separate family Pittidae of the Clamatoridae division of the Anisomyodine Passeres. There are about fifty species, divided into a number of genera, confined to the Old World, and ranging from India and North China to Australia, New Guinea and New Britain, with one species in West Africa, the greatest number being found in Borneo and Singapore. Few birds can vie with the pittas in brightly-contrasted coloration. Deep velvety black, pure white and intensely vivid scarlet, turquoise-blue and beryl-green—mostly occupying a considerable extent of surface—are found in a great many of the species—to say nothing of other composite or intermediate hues; and, though in some a modification of these tints is observable, there is scarcely a true blending of shade, each patch of colour standing out distinctly. This is perhaps the more remarkable as the feathers have hardly any lustre to heighten the effect produced, and in some species the brightest colours are exhibited by the plumage of the lower parts of the body. Pittas vary in size from that of a jay to that of a lark, and generally have a strong bill, a thick-set form, which is mounted on rather high legs with scutellated "tarsi," and a very short tail. In many of the forms there is little or no external difference between the sexes.

Placed originally among the Pittidae, but now created to form an allied family Philepitridae, is the genus Philepitreus, consisting of two species peculiar to Madagascar. The two species which compose it have bills of a more rounded outline than the pittas, and are of a style of coloration and being apparently of more arboreal habits. The sexes differ greatly in plumage, and the males have the skin round the eyes bare of feathers and carunculated. (A. N.)

**Pittacus** of Mytilene in Lesbos (c. 550-570 B.C.), one of the Seven Sages of Greece. About 611, with the assistance of the brothers of the poet Alcaeus, he overthrew Melanouchos, tyrant of Lesbos. In a war (666) between the Mytelenaeans and the Athenians, he slew the Athenian commander Phrynos in single combat. In 589 his fellow citizens entrusted Pittacus with despotic power (with the title of Aesymnetes) for the purpose of protecting them against the exiled nobles, at the head of whom were Alcaeus and his brother Antimenes. He resigned the government after holding it for ten years, and died ten years later. According to Diogenes Laërtius, who credits him with an undoubtedly spurious letter to Croesus (with whom his connexions are probably legendary), Pittacus was a writer of elegiac poems, from which he quotes five lines. His favourite sayings were: "It is hard to be good," and "Know when to act."

See Herodotus v. 27, 94; Diog. Laërt. i. 4; Lucian. *Macrobius*, 18; Strabo xiii. 600, 617-618; Aristotle, *Politics*, ii. 12, iii. 14; T. Berger, *Poetis lyricis graecis*.

**Pittance** (through O. Fr. *planse*, from Lat. *pietas*, loving-kindness), properly a gift to the members of a religious house for masses, consisting usually of an extra allowance of food or wine on occasions such as the anniversary of the donor's death, festivals and the like. The word was early transferred to a charitable donation and to any small gift of food or money.

**Pitt-Rivers, Augustus Henry Lane-Fox** (1827-1900), English soldier and archaeologist, son of W. A. Lane-Fox, was born on the 14th of April 1827. It was not till 1886 that he assumed the name of Pitt-Rivers, on inheriting the Dorsetshire and Wiltshire estates of his great-uncle, the second Lord Rivers. Educated at Sandhurst, he received a commission in the Grenadier Guards in 1845, being captain 1850, lieutenant-colonel 1857, colonel 1867, major-general 1877 and lieutenant-general 1882. He served in the Crimean War, and was at the Alma and the siege of Sebastopol. His talent for experimental research was utilized in investigation into improvements of the army rifle, and he was largely responsible for starting the Hythe School of Musketry. It is not, however, for his military career, but for his work as an anthropologist and archaeologist, that General Pitt-Rivers will be remembered. His interest in the evolution of the rifle early extended itself to other weapons and instruments in the history of man, and he became a collector of articles illustrating the development of human invention. His collection became famous, and, after being exhibited in 1874-1875 at the Bethnal Green Museum, was presented in 1883 to the university of Oxford. When, in 1880, General Pitt-Rivers obtained possession of his great-uncle's estates—practically untouched by the excavator since they had been the battleground of the West Saxons, the Romans and the Britons—he devoted himself to exploring them. His excavations round Rushmore resulted in valuable "finds"; he founded a local museum and published several illustrated volumes. As a scientific archaeologist he attained high rank. Oxford gave him the D.C.L. in 1886; he was president of the Anthropological Institute, and F.R.S. He married, in 1853, Alice Margaret, daughter of the second Lord Stanley of Alderley, and had a numerous family; his second daughter became in 1854 the wife of Sir John Lubbock (Lord Avebury). General Pitt-Rivers died at Rushmore on the 4th of May 1900.

**Pittsburg**, a city of Crawford county, Kansas, U.S.A., about 130 m. S.S.W. of Kansas City. (Pop. 1880, 624; 1890, 667; 1900, 10,112, of whom 850 were foreign-born; (1910 census), 14,755. It is situated at the intersection of four great railway systems—the Atchison Topeka & Santa Fe, the St Louis & San Francisco, the Kansas City Southern (which maintains shops here), and the Missouri Pacific, and is served by inter-urban electric rail lines. The city is the seat of the State Manual Training Normal School (1893) and of the Pittsburg Business College. Pittsburg is situated near the lead and zinc region of south-east Kansas and south-west Missouri, is in the midst of a large and rich bituminous coalfield, and lies near natural gas and oil fields. Among the manufactures are zinc spelter—there are large smelters here—clay products (chiefly vitrified brick, sewer pipe and tile; the clay being obtained from a great underlying bed of shale), blasting powder, packing products, planing mill products. The total value of the city's factory products in 1905 was $1,824,020. Pittsburg was settled about 1879, was chartered as a city in 1880, and became a city of the first class in 1908.

**Pittsburgh**, or Pittsburg, 1 the second largest city of Pennsylvania, U.S.A., and the county-seat of Allegheny county, on the Allegheny, Monongahela and Ohio rivers, 440 m. by rail W. by S. of New York City, 360 m. W. by N. of Philadelphia, 368 m. N.W. of Washington and 468 m. E. by S. of Chicago. Pop. (1890), 238,617; (1900), 321,616, of whom 84,878 were foreign-born, 17,040 were negroes and 154 were Chinese; (1910 census, after the annexation of Allegheny), 533,995. Of the 84,878 foreign-born in 1900, 21,222 were natives of Germany, 18,620 of Ireland, 9,092 of England, 6,243 of Russian Poland, 5,079 of Italy, 4,107 of Russia, 3,553 of Austria, 3,513 of German Poland, 2,559 of Wales, 2,264 of Scotland, 2,124 of Hungary, 1,072 of Sweden and 1,023 of Austrian Poland. Area (including Allegheny, annexed in 1856), 40-57 sq. m. Pittsburgh is served by several divisions of the Baltimore & Ohio, the Pittsburg & Lake Erie (controlled by the New York Central System), the Pittsburg, Cincinnati, Chicago & St Louis (controlled by the Pennsylvania Company), the Pittsburg, Chartiers & Youquotheny (controlled jointly by the two preceding railways; 21 m. of track), the Buffalo, Rochester & Pittsburg, and the Wabash-Pittsburg Terminal (60 m. to Pittsburg Junction, Ohio; controlled by the Wabash railway), and the Pittsburg Terminal (also controlled by the Wabash and operating the

---

1 "Pittsburgh" is the official spelling of the charter and seal; but "Pittsburg" is the spelling adopted by the U.S. Geographic Board and is in more general use.

2 In previous census years the population was as follows: (1800), 1565; (1820), 7248; (1840), 21,115; (1860), 49,221; (1880), 156,389.
West Side Belt, from Pittsburgh to Clairton, 21 m.), railways, and
by river boats on the Ohio, Monongahela and Allegheny.
Picturesque rolling plateaus, the three rivers and narrow
valleys, from which rise high hills or precipitous bluffs, are the
principal natural features of the district over which the city
extends. Retail houses, wholesale houses, banks, tall office
buildings, hotels, theatres and railway terminals are crowded
into the angle, or “The Point,” formed at the confluence of the
Allegheny and Monongahela rivers, with Fifth Avenue as the
principal thoroughfare, especially for the retail houses, and
Fourth Avenue as the great banking thoroughfare. Factories
extend for miles along the banks of all three rivers into the
tributary valleys, and are the cause of Pittsburgh's nickname,
"The Smoky City." The more attractive residential districts
are on the plateau in the eastern portion of the district between
the Allegheny and Monongahela rivers and on the hills over-
looking the Allegheny river from the north. Overlooking the
Monongahela river is Schenley Park (about 422 acres), the first
city park, of which about 400 acres were given to the city in 1890
by Mrs. Mary E. Schenley. About 2 m. to the north, overlooking
the Allegheny river, is Highland Park (about 366 acres), which
contains the city reservoirs and a picturesque lake. Adjacent
to Schenley Park are Homewood and Calvary cemeteries; and
adjacent to Highland Park is Allegheny cemetery. Across the
Allegheny river, in the Allegheny district, are the beautiful
Riverview Park (240 acres), in which is the Allegheny Observa-
yory, and West Park (about 100 acres). A number of bridges
span the rivers.

The city has some fine public buildings, office buildings and
churches. The Allegheny county court-house (1884–1888) is
one of H. H. Richardson's masterpieces. The Nixon theatre
is also notable architecturally. The high Frick Office building
has exterior walls of white granite; in its main hall is a stained-
glass window by John La Farge representing Fortune and her
wheel. A large government building of polished granite con-
tains the post office and the customs offices. St. Paul's Cathedral
(Roman Catholic, 1903–1906) is largely of Indiana limestone.
The city is the see of a Roman Catholic and a Protestant Episco-
pal bishop. In Schenley Park is the Carnegie Institute (estab-
lished by a gift of $10,000,000 from Andrew Carnegie, who made
further contributions of $9,000,000 for its maintenance), with
a main building containing a library; a department of fine arts,
a museum (see MUSEUMS OF SCIENCE) and a music hall, and
several separate buildings for the technical schools, which had
2102 students in 1909. The main building, dedicated in April
1907, is 660 ft. long and 400 ft. wide; in its great entrance hall
is a composition by Augustus Saint-Gaudens, who was born a
native of the city. The library, in which the institution had
its beginning in 1895, contains about 306,000 volumes.
The Phipps Conservatory was presented to the city in 1893 by Henry
Phipps (b. 1839), a steel manufacturer associated with Andrew
Carnegie. It is the largest in America, and, with its Hall of
Botany, which is utilized in instructing school children in botany,
is situated in Schenley Park. The conservatory is maintained
by municipal appropriations. There is a zoological garden in
Highland Park. In December 1907 it was decided that the
several departments of the Western University of Pennsylvania,
then in different parts of the city, should be brought together
on a new campus of 43 acres near the Carnegie Institute. In
July 1908 the name was changed to "The University of Pitts-
burgh." The university embraces a college and engineering
school, the Western Pennsylvania School of Mines and Mining
Engineering, a graduate department, an evening school of
Economics, accounts and finances, a summer school, evening
classes, Saturday classes, and departments of astronomy (the
Allegheny Observatory, in the Allegheny district), law (the Pitts-
burgh Law School), medicine (the Western Pennsylvania Medical
College), pharmacy (the Pittsburgh College of Pharmacy) and
dentistry (the Pittsburgh Dental College). The institution had
its beginning in the Pittsburgh Academy, which was opened about
1770 and was incorporated in 1787. It was incorporated
as the Western University of Pennsylvania in 1819,
great fleets of barges carry coal and other heavy freight, such as steel rails, cotton ties, sheet iron, wire and nails, down the Ohio in the winter and spring. A ship canal to provide water communication between Pittsburgh and Lake Erie has been projected. The railways have a heavy tonnage of coal, coke and iron and steel products, and a large portion of the iron ore that is produced in the Lake Superior region is brought to Pittsburgh. In 1908 the river traffic amounted to 9,000,146 tons, most of which was carried on barges down the Ohio. Pittsburgh is also a port of entry; in 1907 the value of its imports amounted to $2,116,367, and in 1906 to $2,062,162.

The value of the factory products in 1905 was $165,428,881, and to this may be added $45,830,272 for those of the city of Allegheny, making a total of $211,259,153. In the manufacture of iron and steel products Pittsburgh ranks first among the cities of the United States, the value of these products amounting in 1905 to $88,250,805 or 53.3% of the total for all manufactures; if the manufactures of Allegheny be added they amounted to $92,939,860 or 43.7%. Several neighboring cities and towns are also extensively engaged in the same industry, and in 1905 Allegheny County produced about 48% of the pig iron, nearly 34% of the Bessemer steel, more than 44% of the open-hearth steel, more than 53% of the crucible steel, more than 24% of the steel rails, and more than 50% of the structural shapes that were made in that year in the United States. The value of Pittsburgh's foundry and machine-shop products was $6,931,514; of the product of steam railway repair shops, $3,726,990 (being 428% more than in 1900); of malt liquors, $3,166,839; of slaughtering and meat-packing products, $2,722,072; of cigars and cigarettes, $2,207,228; of glass, $2,130,540; and of tin and terne plate, $1,045,570. Electrical machinery, apparatus and supplies were manufactured largely in the city (value in 1905, $1,769,537), and there was another large plant for their manufacture immediately outside of the city limits. Coke, cut cork, rolled brass and copper were other important products in 1905. In 1900, and for a long period preceding, Pittsburgh ranked first among American cities in the manufacture of glass, but in 1905 it was outranked in this industry by Muncie, Indiana, Millville, New Jersey, and Washington, Pennsylvania; but in the district outside of the city limits of Pittsburgh much glass is manufactured, so that the Pittsburgh glass district is the greatest in the country, and there are large glass factories at Washington (18 m. south-west), Charleroi (20 m. south) and Tarentum (15 m. north-east). In Pittsburgh or the immediate vicinity are the more important plants of the United States Steel Corporation, including that of the Carnegie Company. Here, too, are the plants of the Westinghouse Company for the manufacture of electrical apparatus, of air brakes invented by George Westinghouse (born 1846), and of devices for railway signals which he also invented. In the Allegheny district the H. J. Heinz Company has its main pickle plant, the largest establishment of its kind in the country.

The Pittsburgh charter of 1816 vested the more important powers of the city government in a common council of 15 members and a select council of 9 members, and until 1834 the mayor was appointed annually by these city councils from their own number. By the Wallace Act of the state legislature in 1874 a form of government was provided for cities of three classes, and Pittsburgh became a city of the second class (population between 100,000 and 500,000); under the act of 1895 a new classification was made, under which Pittsburgh remains in the second class. An act of 1887 had amended the provisions of the Wallace Act in regard to second class cities by changing the terms of select councilmen from two to four years and of common councilmen from one to two years. In 1901 a new act was passed for the government of cities of the second class. It provided that the executive be a "city recorder"; this provision was repealed in 1903, when the title of mayor again came into use. The mayor holds office for three years, has the powers and jurisdiction of a justice of the peace, appoints the heads of departments (public safety, public works, collector of delinquent taxes, assessors, city treasurer, law, charities and correction, and sinking fund commission), and may remove any of the officers he has appointed, by a written order, showing cause, to the select council. The city controller is elected by popular vote. The legislative bodies are the select and common council, elected under the law of 1887; by a three-fifths vote it may pass resolutions or ordinances over the mayor's veto. The department of public safety controls the bureaus of police, detectives, fire, health, electricity and building inspection; the department of public works controls bureaus of surveys, construction, highways and sewers, city property, water, assessment of water rents, parks, deed registry, bridges and light. In 1909 the taxable valuation was $100,771,321, and the tax rate was 13.8 mills for city property, 9.2 mills on rural property and 6.9 mills on agricultural property. The tax rate for separate indebtedness varied from 6.5 mills in Allegheny to 16-2 mills in the 43rd ward. The water-supply of Pittsburgh is taken from the Allegheny river and pumped into reservoirs, the highest of which, in Highland Park, is 367 ft. above the river; and there is a slow sand filtration plant for the filtration of the entire supply.

Pittsburgh owed its origin to the strategic value of its site in the struggle between the English and the French for the possession of the North American continent. A few Frenchmen attempted to establish a settlement here in 1731, but were soon driven away by the Indians. In 1753, after the French had laid formal claim to this region and the Ohio Land Company had been formed with a view to establishing a settlement within it, Robert Dinwiddie, governor of Virginia and a shareholder in the Ohio Company, sent George Washington with a letter to "the commandant of the French forces on the Ohio" (then stationed at Fort Le Boeuf, near the present Waterford, about 115 m. north of the head-waters of that river) asking him to account for his invasion of territory claimed by the English. This was Washington's first important public service. He reached the present site of Pittsburgh on the 24th of November 1753, and subsequently reported1 that what is now called "The Point," i.e. the tongue of land formed by the confluence of the Monongahela and Allegheny rivers, was a much more advantageous situation for a fort and trading post than the one about two miles up the Monongahela (near the present site of McKees Rocks) which had been tentatively selected by the Ohio Company. Accordingly, on the 17th of February 1754, a detachment of about 40 soldiers, under the command of Captain William Trent, reached "The Point," and began to build a fortification (under the auspices of the Ohio Company), which it seems to have been the intention to call Fort Trent, and which was the beginning of the permanent settlement here by whites. On the 17th of the following April, however, Ensign Edward Ward, commanding the soldiers, in the absence of Captain Trent, was forced to evacuate the unfinished fortification by a party of about 1000 French and Indians, under Captain Contrecœur, who immediately occupied the works, which he enlarged and completed, and named Fort Duquesne, in honour of Duquesne de Menneville, governor of New France in 1752-1755. In the following summer Washington attempted to recover this fort, in a campaign which included the skirmish at Fort Pitt, was ruined during Pontiac's conspiracy. At the beginning of the War of Independence he was given a major's commission to raise troops in Western Pennsylvania. See Journal of Captain William Trent (Cincinnati, Ohio, 1871), edited by Alfred T. Goodman.

1 His Journal published in 1754, gives a concise and lucid account of this expedition.

William Trent (c. 1715-1728) was a native of Lancaster county, Pennsylvania, became a captain in the state militia in 1746 and served against the French and Indians, was, for many years, after 1749, a justice of the court of common pleas and general sessions of the peace for Cumberland county, Pennsylvania, and in 1750-1756 was a member of the council of Cogan in an extensive war against the Indians. According to one account, he visited the site of Pittsburgh, and examined its availability for fortification, in August 1753—before the arrival of Washington. In 1755 he was a member of the council of Lieutenant Governor Robert H. Morris, and in 1758 he accompanied General Forbes' expedition against Fort Duquesne. He acted many times as Indian agent; his lucrative trade with the Indians, conducted from a trading house near Fort Pitt, was ruined during Pontiac's conspiracy. At the beginning of the War of Independence he was given a major's commission to raise troops in Western Pennsylvania. See Journal of Captain William Trent (Cincinnati, Ohio, 1871), edited by Alfred T. Goodman.
PITTSBURG

681

(commonly considered the beginning of the French and Indian—Seven Years—War) on the 28th of May 1754, at Great Meadows (in what is now Wharton township, Fayette county, Pennsylvania, about 30 m. south-east of Pittsburg), between a detachment under his command and a scouting party under N. Coulon de Jumonville, in which Jumonville and several of his men were killed; the building, at Great Meadows, by Washington, of Fort Necessity, and its capitulation (July 3); and the retreat of Washington to Virginia. Another expedition, led by Major-General Edward Braddock, resulted in the engagement known as "Braddock's Defeat" (July 9, 1755), fought within the present borough of Braddock (about 8 m. east of Fort Duquesne), in which Braddock's force was practically annihilated, and Braddock was mortally wounded, dying four days later. The fort was finally recaptured by the English in 1758, as the result of an elaborate expedition (involving about 7000 troops) planned by Brigadier-General John Forbes (1710-1758), and prosecuted, with the assistance of Colonel George Washington and Colonel Henry Bouquet, in the face of great difficulties. General Forbes himself was so ill that he had to be carried in a litter throughout the campaign. The troops having rendezvoused during the summer (of 1758) at Ray's Town (now Bedford, Pennsylvania), and at Loyalhanna creek (now in Westmoreland county), about 50 m. to the north-west (where Fort Ligonier was built), Colonel Bouquet, commanding the division at the latter place, despatched Major James Grant (1720-1806) at the head of about 850 men to reconnoitre the fort. Grant advanced to a hill (still known by his name, and upon the crest of which the court-house now stands) within about a quarter of a mile of the fort. Here he rashly divided his force, and in a sortie of French and Indians, on the morning of the 14th of September, one of his divisions was surrounded, and a general rout ensued in which about 270 of Grant's men were killed, about 40 were wounded, and others (including Grant) were taken prisoners. Forbes's army advanced 10 within about 15 m. of the fort on the 24th of November, whereupon the French blew up part of the works, set fire to the buildings and retreated down the Ohio in boats. The English occupied the place on the next day and General Forbes ordered the immediate erection of a stockade fort near the site of the old one. In reporting to Lieut.-Governor William Denny (Nov. 26) the success of the expedition he dated his letter from Fort Duquesne "or now Pitts-Bourgh," and this name, with its subsequent modification "Pittsburgh," was thereafter more commonly used than that of Fort Pitt, which, as designating the fortification proper appears to have been first applied by General John Stanwix to the enlarged fort built (at a cost, it was estimated, of £60,000) chiefly under his direction (June 1759 — July 1760).

The first considerable settlement around the fort sprang up in 1760; it was composed of two groups of houses and cabins, the "lower town," near the fort's ramparts; and the "upper town," built chiefly along the banks of the Monongahela, and extending as far as the present Market Street. In April 1761, according to a census of the settlement, outside of the fort, taken for Colonel Bouquet, there were 332 inhabitants and 104 houses.

Fort Pitt was one of the important objective points of Pontiac's conspiracy (1763), and as soon as the intentions of the Indians became evident, Captain Simeon Ecuyer, the Swiss officer in command of the garrison (which then numbered about 330), had the houses outside the ramparts levied and prepared for a siege. The Indians attacked the fort on the 22nd of June (1763), and kept up a continuous, though ineffective, fire upon it until the 27th of July until the 1st of August, when they drew off and advanced to meet the relieving party under Colonel Bouquet. They were defeated at Bushy Run, and Colonel Bouquet relieved the fort on the 10th of August (see PONTIAC). In 1764 Colonel Bouquet added to the fort a redoubt, the "Block House," which still stands, the sole remaining trace of Fort Pitt, and is owned and cared for by the Daughters of the American Revolution.

A second town, laid out in 1764, by Colonel John Campbell (with the permission of the commandant at Fort Pitt), is bounded in the present city by Water Street, Market Street, Second Avenue and Ferry Street, and comprises four blocks. In November 1768, at a general council of the Six Nations with Sir William Johnson and representatives of Pennsylvania and Virginia held at Fort Stanwix, on the site of the present Rome, New York (q.v.), at which was signed a treaty establishing the boundary line between the English possessions and the territory claimed by the Six Nations, the Indians sold for $10,000 to Thomas Penn (1702-1775) and Richard Penn (1706-1771), respectively, the second and third sons of William Penn—the founder of Pennsylvania—by his second wife, the remaining land in the province of Pennsylvania to which they claimed title, namely the tract lying south of the west branch of the Susquehanna river and of a straight line from the north-west corner of what is now Cambria county to the present Kittanning (in Armstrong county), and all of the territory east of the Allegheny river below Kittanning and south of the Ohio river. To this transaction the commissioner from Virginia seems to have made no objection, though the tract included the Fort Pitt region and other territory then claimed by Virginia. In January-March 1769 the Penns caused to be surveyed the "Manor of Pittsburg," a tract of about 5700 acres, including much of the original city, intending to reserve it for their private use; but in the following April they offered at public sale the lands in the remainder of their purchase of the preceding year. At this time the settlement about Fort Pitt consisted of about twenty houses, occupied chiefly by Indian traders. By order of General Thomas Gage the fort was abandoned as a military post in October 1772, and was partly dismantled. In January 1774 it was occupied by an armed force under Dr John Connolly, a partisan of Lord Dunmore, governor of Virginia, and by him was named Fort Dunmore (which name, however, was never formally recognized), this being one of Dunmore's overt acts ostensibly in support of his contention that the Fort Pitt region was included in Augusta county, Virginia. In the following April Connolly took forcible possession of the court-house at Hanna's Town (near the present Greensburg), the county-seat of Westmoreland county (which then included the Fort Pitt region), a few days afterwards arrested the three justices who lived in Pittsburg, and for the remainder of the year terrorized the settlement. Lord Dunmore himself issued a proclamation dated "Fort Dunmore," 17th September (1774), in which he called upon the inhabitants to ignore the authority of Pennsylvania, and to recognize only that of Virginia. A year afterwards Fort Pitt was occupied by a company of Virginia soldiers by order of the Virginia Provincial Convention (assembled at Williamsburg in August 1775), but thismove caused a great deal of mischief and there was a more active war than an expression on the Pennsylvania-Virginia boundary dispute; and, in November, Connolly was arrested at Fredericksburg, Maryland, on the charge of furthering Dunmore's plans for invading the western frontier. The boundary itself was in controversy until 1780, and the marking of the boundary lines was not completed until 1785. During the War of Independence the fort was maintained as a frontier Indian post, and as a protection against the British at Detroit. Soon after the close of the war it was neglected, and by 1791 it was in bad repair; therefore at the time of the Indian hostilities of 1792 another stockade fort was built near the bank of the Allegheny river and about a quarter of a mile above the site of Fort Pitt, this new fort being named Fort Lafayette, or, as it was more commonly called, Fort Fayette. After General Anthony Wayne's defeat of the Indians, at Fallen Timbers, Ohio (Aug. 20, 1794), Pittsburg lost its importance as a frontier post.

In January 1784 the sale of the land included in the "Manor of Pittsburg" was begun by the grandchildren of William Penn, John Penn (1720-1795), the second son of Richard Penn and lieutenant-governor of Pennsylvania in 1763-1771 and in 1773-1776; and John Penn (1706-1734), the fourth son of Thomas Penn; and in the following June a new series of town lots was laid out in which was incorporated Colonel Campbell's survey. Thereafter, settlers, chiefly Scotch and Irish, came rapidly.

1 This tract was confiscated by Pennsylvania in 1779.
PITTSFIELD—PITSTON

Pittsburg and its vicinity witnessed much of the disorder, and some of the violence against person and property, incident to the Whisky Insurrection of 1802. Delegates from Allegheny, Westmoreland, Washington and Fayette counties met here on the 7th of September 1791, and passed resolutions severely denouncing the excise tax; and a similarly constituted gathering, on the 24th of August 1792, voted to proscribe all persons who assisted in the enforcement of laws taxing the manufacture of liquor. Thereafter various persons who had paid the excise tax, or had assisted in collecting it, were tarred and feathered or had their houses or barns burned. General John Neville (1731-1803), having accepted the office of chief excise inspector for Western Pennsylvania, his line country residence, about 7 m. south-west of Pittsburg, was attacked by a mob of about 500 men on the 16th and 17th of July 1794. The defenders of the property (who included a squad of soldiers from the garrison at Pittsburg) killed two and wounded several of the attacking party, but they were finally forced to surrender, and General Neville's mansion and other buildings were burned to the ground. A mass meeting of about 5000 citizens of the above-mentioned counties (many of them armed militiamen), at Braddock's Field, on the 1st and 2nd of August 1794, threatened to take possession of Fort Lafayette and to burn Pittsburg, but cooler counsel prevailed, and after voting to proscribe several persons, and marching in a body through the streets of the town, the crowd dispersed without doing any damage. Upon the arrival in the following November of the troops sent by President Washington, a military court of inquiry, held at Pittsburg, caused the arrest of several persons, who were sent to Philadelphia for trial, where some of them were found guilty and sentenced to terms of imprisonment, but the sentences were not enforced.

The town was made the county-seat in 1791, it was incorporated as a borough in 1794, the charter was revived in 1804, and the borough was chartered as a city in 1816. As early as the year of its incorporation as a borough Philadelphia and Baltimore merchants had established an important trade with it. Their goods were carried in Conestoga wagons to Shippensburg and Chambersburg, Pennsylvania, and Hagerstown, Maryland, taken from there to Pittsburg on pack horses, and exchanged for Pittsburg products; these products were carried by boat to New Orleans, where they were exchanged for sugar, molasses, &c., and these were carried through the gulf and along the coast to Baltimore and Philadelphia. Boat-building was begun in Pittsburg in 1797 or earlier; the galley "President Adams," built by the government, was launched here in 1798, and the "Senator Ross," completed in the same year, was launched in 1799. In 1797 glassworks which were the first to use coal as a fuel in making glass were built here; later Pittsburg profited greatly by the use of its great store of natural gas in the manufacture of glass. In 1806 the manufacture of iron was well begun, and by 1835 this had become the leading industry. On the 10th of April 1845 a considerable portion of the city was swept by fire, and in July 1877, during the great railway strike of that year, a large amount of property was destroyed by a mob. The commercial importance of the city was increased by the canal from Pittsburg to Philadelphia, built by the state in 1834 at a cost of $10,000,000. The first petroleum pipe line reached Pittsburg in 1875. A movement to consolidate the cities of Pittsburg and Allegheny, together with some adjacent boroughs, was begun in 1833-1834. It failed entirely in that year but in 1867 Lawrenceville, Peebles, Collins, Liberty, Pitt and Oakland, all lying between the two rivers, were annexed to Pittsburg; in 1872 there was a further annexation of a district embracing 27 sq. m. south of the Monongahela river; in 1906 Allegheny (q.v.), although a large majority of those voting on the question in that city were opposed to it, was annexed, and in November 1907 the Supreme Court of the United States declared valid the act of the state legislature under which the vote was taken.

PITTSFIELD, a city and the county-seat of Berkshire county, Massachusetts, U.S.A., in the western part of the state among the Berkshire Hills, and about 150 m. W. of Boston. Pop. (1800), 17,281; (1900), 21,766, of whom 4344 were foreign-born; (1910 census), 25,121. Area, about 41 sq. m. It is served by the New York, New Haven & Hartford and the Boston & Albany (New York Central & Hudson River) railways, and by two inter-urban electric lines. Pittsfield is a popular summer resort; it lies in a plain about 1000 ft. above sea-level, is surrounded by the picturesque Berkshire Hills, and is situated in a region of numerous lakes, one of the largest—Lake Ponatouusc—being a summer pleasure resort. On either side of the city flow the east and west branches of the Housatonic river. Standing in the public green, in the centre of the city, is the statue (by Launt Thompson) of the "Massachusetts Color Bearer," which has been reproduced on the battlefield of Gettysburg, Pennsylvania. The principal institutions are the House of Mercy Hospital, with which is connected the Henry W. Bishop Memorial Training School for nurses, the Berkshire Home for aged women, the Berkshire Athenaeum, containing the public library, the Crane Art Museum and a Young Men's Christian Association. Prominent buildings are St. Joseph's Cathedral and the buildings of the Berkshire Life Insurance Company, the Agricultural National Bank and the Berkshire County Savings Bank. In the south-western part of Pittsfield, on the boundary between it and Hancock, is Shaker Village, settled about 1790 by Shakers. Pittsfield was a water-power and foundry manufacturing industry. In 1905 its factory products were valued at $8,577,358, or 49½% more than in 1900. Fully half of the manufactures consist of textile goods.

The first settlement in which is now Pittsfield was made in 1743, but was soon abandoned on account of Indian troubles. In 1749 the settlement was revived, but the settlers did not bring their families to the frontier until 1752. The settlement was first called "Boston Plantation," or "Poontosuck," but in 1761, when it was incorporated as a township, the name was changed to Pittsfield, in honour of the elder William Pitt. In 1801 Pittsfield was chartered as a city. It was here, in the Appleton (or Plunkett) House, known as "Elm Knoll," and built by Thomas Gold, father-in-law of Nathan Appleton, that in 1845 Henry W. Longfellow (who married Nathan Appleton's daughter) wrote his poem "The Old Clock on the Stairs." For thirty years (1842-1872) Pittsfield was the home of the Rev. John D. Appleton, the author of numerous books, including Lectures to Children (1834); 2nd series, 1838) and The Student's Manual (1835) were once widely read. From 1807 to 1816 Elkanah Watson (1758-1842), a prominent farmer and merchant, lived at what is now the Country Club, and while there introduced the merino sheep into Berkshire county and organized the Berkshire Agricultural Society; he is remembered for his advocacy of the building of a canal connecting the Great Lakes with the Atlantic Ocean; and as the author of Memoirs: Men and Times of the Revolution (1835), edited by his son, W. C. Watson.

PITSTON, a city of Luzerne county, Pennsylvania, U.S.A., on the Susquehanna river just below the mouth of the Lackawanna, about 11 m. S.W. of Scranton and about 9 m. N.E. of Wilkes-Barre. Pop. (1800), 10,321; (1900), 12,556, of whom 3394 were foreign-born; (1910 census), 16,267. It is served by the Erie, the Lehigh Valley, the Delaware, Lackawanna & Western, the Central of New Jersey, the Delaware & Hudson, and the Lackawanna & Wyoming Valley railways; there is an electric railway from Pittston to Scranton, and a
PITYRIASIS—PIUS (POPES) 683

belt-line electric railway connects Pittston with Avoca, Nanticoke, Plymouth and Wilkes-Barre. Two bridges connect the city with the borough of West Pittston (pop., 1910, 68,828). Pittston is in the midst of the richest anthracite coal region of the state, and fire-clay also abounds in the vicinity. In 1905 the value of the factory products was $1,474,928 (47.8% more than in 1900). Pittston, named in honour of William Pitt, earl of Chatham, was one of the five original towns founded in the Wyoming Valley by the Susquehanna Company of Connecticut; it was first settled about 1770 and was incorporated as a borough in 1803. It was chartered as a city in 1894.

PITYRIASIS VERSICOLOR (Gr. πιτυριασις, scurf, from πιτυρος, bran), a skin disease, consisting of patches of brownish discolorations of various sizes and shapes, mostly on the front of the body, and often attended with itching, especially after heating exercise. The pigmentation seems to radiate from the orifices of hair-follicles. The epidermis in a scaly condition over the patch, and among the débris of the epidermic cell there may be seen minute oval spores due to a vegetable parasite, the Microsporon furfur. The disease is mostly one of adult age, found all over the world, and not associated in any special way with poor general health. The treatment consists of rubbing in an ointment of potassium sulphide or one of the mercurial ointments, or using sulphur-soap habitually.

PIURA, the northernmost maritime department of Peru, bounded north by the Gulf of Guayaquil, N.E. by Ecuador, S. by the departments of Cajamarca and Lambayeque, and W. by the Pacific. Area, 14,840 sq. m.; pop. (1906, estimate), 154,080—both totals exclusive of the province of Tumbes, or Tumbez (area, about 1780 sq. m.; pop., in 1906, about 8000), which has been administratively separated from the department for military reasons. The department borders partly to the arid coastal plain that extends from the Gulf of Guayaquil southward nearly to Valparaiso, and partly to a broken mountainous region belonging to the Western Cordilleras. The coastal zone is traversed by the Tombe, Chincha and Piura rivers, which have their sources in the melting snows of the higher Andes and flow westward across the desert to the coast. The valleys of the Chira and Piura are irrigated and maintain large populations. Rough cotton, called "vegetable wool," and tobacco are the principal products, and are also produced in the valley of the Tumbes and in some of the elevated mountain districts. On the upland pastures cattle have long been raised, and goat-breeding has been added in modern times. Mules also are reared.

Petroleum is an important product, and there are wells at a number of places along the coast, from Tumbez to Sechura, the most productive being those of Talara and Zorritos. There are sulphur deposits in the Sechura desert, and salt is manufactured at some places on the southern coast. The making of Panama hats from the fibre of the "toquilla" palm is a household industry. The capital is Piura (est. pop. 9100 in 1906), on the Piura river, about 35 m. (direct) E.S.E. of Paita, and 104 ft. above sea-level. It is founded by Piura (1470), a settlement of the name of San Miguel, at a place called Tangarara, nearer Paita, but the present site was afterwards adopted. A railway (60 m. long) by way of Sullana connects with the port of Paita, and an extension of 6 m. runs S.S.E. to Catacaos. Other towns of the department, with their estimated populations in 1906, are: Tumbes, or Tumbez (2300), the most northern port of Peru, on the Gulf of Guayaquil, celebrated as the place where Pizarro landed in 1531; Paita; Sechura (6450), on Sechura Bay in the southern part of the department, with exports of salt and sulphur; Sullana (3500), an inland town with railway connections in the fertile Chira valley; Morropón (3800) on the upper Piura; Huancahamba, the centre of a tobacco district in the mountains; and Tambo Grande (6100) and Chulucanas (4600), both in the fertile Piura valley above the capital.

PIUS, the name of ten popes.

Pius I., pope from about 141 to 154. He was the brother of Herodes, author of the Shepherd.

Pius II. (Enea Silvio de' Piccolomini, known in literature as Aeneas Silvius), pope from 1458 to 1464, was born on the 18th of October 1405 at Corsignano (afterward called Pienza after him), near Siena. His family, though poor, was noble, and claimed to trace descent from Romulus. The eldest of eighteen children, he had to work on the farm with his father, until a priest taught him the rudiments of letters, which enabled him, at the age of eighteen, to go as a poor student to Siena, dividing his time between severe humanistic studies and a life of sensil pleasure. He was attracted to Florence by the teaching of Filippo. His father urged him to become a lawyer, but he accepted the position of secretary to Domenico Capranica, bishop of Fermo, and went with him to the council of Basel, where he stayed several years (1431–1435), changing masters whenever he could improve his position. As secretary of the bishop of Novara he became engaged in a conspiracy against Pope Eugenius IV.; his master was caught and imprisoned, and Aeneas only saved himself by a hasty flight. He was next (1435) employed as secretary of Cardinal Nicholas Albergatti (d. 1443) at the congress of Arras, where peace was made between France and Burgundy. From here he took a long journey to Scotland and England, on a secret diplomatic mission; he had numerous adventures, in one of which he nearly lost his life. In 1436 he was back at Basel, and, although a layman, obtained a seat in the council and exercised considerable influence. In order to control it better Eugenius tried to get the council to move to Florence; a minority agreed and seceded; the majority, however, stayed where they were and took vigorous measures against the pope, culminating in his deposition on the 25th of June 1438. Aeneas took an active part in the council; and though he still declined to take orders, he was given a position on the conciliar conclave which elected Amadeus of Savoy as pope under the title of Felix V. In return for his services Felix made Aeneas papal secretary.

A new period of his career opened in 1442, when he was sent by the council to take part in the diet of Frankfort-on-Main. Here he met Frederick III. of Germany, who made him poet laureate, and also became secretary. He ingratiated himself with the chancellor, Kaspar Schlick, at Vienna, one of whose adventures he celebrated in Lucrétia et Euryalias, a novel in the style of Boccaccio. At this period he also wrote his witty and immoral play, Chirisia. In 1446 he took orders as subdeacon, and wrote that he meant to reform, "forsaking Venus for Bacchus," chiefly on the ground of satiety, and also, as he frankly wrote, because the clerical profession offered him more advantages than he could secure outside it.

Aeneas was useful to Frederick as a diplomatist, and managed to give all parties the impression that he was the devoted advocate of each. During the struggle between pope and council he induced Frederick to be neutral for a while. He took an important part in the diet of Nuremberg (1444), and being sent on an embassy to Eugenius in the following year he made his peace with the pope. At the diet of Frankfort (Sept. 1446) Aeneas was instrumental in changing the majority of the electors from their hostile position towards pope and emperor into a friendly one. He brought the good news to Eugenius shortly before his death (Feb. 7, 1447), and made friends with the new pope, Nicholas V., by whom he was made bishop of Siena. He was an agent of Frederick in making the celebrated concordat of Vienna (also called concordat of Aschaffenburg) in February 1448. His services to pope and emperor brought him the titles of prince of the empire and cardinal, positions which he used rather unscrupulously to get as many lucrative benefices into his hands as possible. Those in Germany brought him two thousand ducats a year.

The death of Calixtus III. (who succeeded Nicholas V.) occurred on the 5th of August 1455. After a hot fight in the conclave, in which it seemed that the wealthy French cardinal, Guillaume d'Estouville, archbishop of Rouen and bishop of Ostia, would be elected, the intrigues of Aeneas and of his friend Rodrigo Borgia (later the notorious Alexander VI.) gave the victory to the cardinal of Siena, who took the title Pius II., with a reminiscence of Virgil's "pia Aeneas." The humanists hailed his election with joy, and flocked around to secure a share
PIUS (POPES)

of the good things, but they were bitterly disappointed, as Pius did not prove himself the liberal and undis appointed patron they hoped. The fall of Constantinople in 1453 had made a deep impression upon Pius, and he never ceased to preach the crusade against the Turks. In September 1459 he opened a congress at Mantua for the purpose of considering what could be done in this direction. His proposals for the raising of troops and money met with general opposition. The French were angry because Pius had crowned the Spanish claimant, Ferdinand, king of Naples, and thus disposed of the pretensions of René of Anjou. The Germans also objected to Pius's plans, but finally agreed to furnish some troops and money, promises which they did not carry out. Pius felt how much the position of the papacy had fallen in importance since the days of Urban and Innocent III., and, believing that the change was due to the general councils which had asserted power over the popes, he changed his position, which before his election to the papal throne had been that of a warm advocate of the conciliar claims, and issued (Jan. 1460) the bull Exequeribilis et in pristinis temporibus inauditus, in which he condemned that the councils were superior to the popes, and proclaimed the anathema against anyone who approved of his measures. He issued another bull at the same time, promising forgiveness of sins to those who would take part in the crusade, and then dissolved the congress.

While Pius was at Mantua war broke out between the French and Spanish in southern Italy, and a rising of the barons devastated the Campagna. Hurrying back to Rome Pius succeeded in quelling the disorders, and sent his nephew Antonio Todeschini to the aid of Ferdinand, who made him duke of Amalfi and gave him his natural daughter Maria in marriage. This measure still further alienated the pope from the French, with whom he was at that time negotiating for the abrogation of the Pragmatic Sanction. When Louis XI. came to the throne (Nov. 1461), he sent to Pius saying that he had abolished the Pragmatic Sanction, hoping in return to get the kingdom of Naples for his countryman René of Anjou. When Pius refused to do anything to the prejudice of Ferdinand, Louis changed his attitude, and allowed the contests of the university of Paris and the parlement to persuade him to restore the ancient liberties of the Gallican Church. At the same time a serious quarrel with the Germans prevented anything being done towards a crusade. George Podiebrad, king of Bohemia, was plotting to depose the emperor Frederick III., who was supported by Pius. Diether, archbishop of Mainz, took the side of Podiebrad, and replied to Pius's measures by appealing to a general council. He was declared deposed by the pope, but kept his seat, and in 1464 compelled the pope to recognize him again. The quarrel with Podiebrad, who was accused of supporting the Utraquist heresy, continued with increasing bitterness, but without any decisive result, until the death of Pius. In the meantime the pope did what he could to further the cause of the crusade. The discovery of alum mines at Tolfa gave him an unexpected pecuniary resource, and to stimulate the zeal of Christendom, Pius took the cross on the 18th of June 1464. He set out for Venice, where he intended to sail for the East, but he was attacked with a fever, and on the 14th of August 1464 he died.

Pius III. was a voluminous author. Besides poems, a novel and a play, he wrote a number of orations, which were considered models of eloquence in their day. His most valuable work, however, is his Commentaries, a history of his own life and times, told in an interesting and rational manner. He is very frank about himself, and most of the adverse judgments which have been pronounced on his character have been based on his own confessions. He was an opportunist, sailing along with any favourable breeze, and not quite enough in earnest about anything to pursue the same tack steadily for long. We must give him the credit, however, of advocating a statesmanlike policy in the interests of the whole of Europe in trying to get the powers to unite against the Turks, who threatened to overwhelm them all.

See Herzog-Hauck, Realencyclopaedie (1904), vol. xv., where a full bibliography will be found; M. Creighton, History of the Papacy during the Reformation, vol. ii. (London, 1882); L. Pastor, History of the Popes from the close of the Middle Ages (Eng. trans., 1896, vol. ii.); Vogt, Pius III. (1845-1863). The Commentaries of Pius were published in 1584, under the name of Gobelinus Persona. His other works are found in Aeneae Silvii opera omnia (Basel, 1551). See also W. Bouling, Aeneas Silvius (1909). (P. Sm.)

Pius III. (Francesco Nanni-Todeschini-Piccolomini), pope from the 22nd of September to the 18th of October 1553, was born at Siena on the 9th of May 1439. After studying law at Perugia, he was made archbishop of Siena and cardinal-deacon of St Eustachio, when only twenty-two years of age, by his uncle Pius II., who permitted him to assume the name and arms of the Piccolomini. He was employed by subsequent popes in several important legations, as by Paul II. at the diet of Regensburg, and by Sixtus IV. to secure the restitution of ecclesiastical authority in Umbria. He bravely opposed the policy of Alexander VI., and was elected pope, amid the disturbances consequent upon the death of the latter, through the influence of Cardinal della Rovere, afterwards Julius II., and was crowned on the 8th of October 1503. He permitted Cesare Borgia to return to Rome, but promptly took in hand the reform of the curia. Pius was a man of blameless life, and would doubtless have accomplished much had he lived. His successor was Julius II.

Pius IV. (Giovanni Angelo Medici, or "Medighino"), pope from 1559 to 1565, was born at Milan on the 31st of March 1496, of an obscure family, not related to the Medici of Florence (a claim to such relationship was advanced after Giovanni Angelo had attained to prominence). The fortune of the family was established by an elder brother, Gian Giacomo, who fought his way to the marquisate of Marignano and distinguished himself in the service of the emperor. Giovanni Angelo studied in Bologna and Pavia, and for some time followed the law. Entering the service of the Church, he found favour with Paul III., who entrusted him with the government of several important territories, and in 1549 made him a cardinal. Julius III. sent him upon the Helvetic Synod of 1551. With Paul IV. he was out of favour, because not in sympathy with his policy, and accordingly retired to Milan. In the protracted and momentous concile that followed the death of Paul the election of Pius (Dec. 25, 1559) was due to a compromise between the Spanish and French factions.

In temperament and habit Pius was the antithesis of his predecessor: affable, vivacious, convivial. He was, moreover, astute, diplomatic and experienced in affairs. He allowed the reform movement free course, but tried to repair certain injustices of Paul IV. (for example, releasing and reinstating Morone, who had been imprisoned on a charge of heresy), and mitigated some of his extreme decrees. But to the nephews of Paul he showed no mercy: they were charged with various crimes, condemned, upon testimony of suspicious validity, and executed on the 5th of March 1561. The Colomnesi, who had been active in the prosecution, recovered Palliano. But under Pius V. judgment was reversed, the memory of the Caraffa rehabilitated, and restitution made to the family. Pius IV. himself was not guiltless of nepotism; he the bestowment of the cardinalate and the archbishopric of Milan upon his nephew, the pure and upright Carlo Borromeo, redounded to the honour of his pontificate and the welfare of the church.

With England lost to the papacy, Germany overwhelmingly Protestant, and France on the verge of civil war, Pius realized how fatuous was the anti-Spanish policy of his predecessor. He therefore recognized Ferdinand as emperor, and conciliated Philip II. with extensive ecclesiastical privileges. But subsequently, antagonized by Philip's arrogance, he inclined towards France, and gave troops and money for the war against the Huguenots.
After a suspension of ten years the council of Trent reconvened on the 18th of January 1562. Among the decrees presented by the various nations was the recognition of the equality of the episcopate, communion in both kinds, clerical marriage, and the use of the vernacular in Church services. It required all the pope's diplomacy to avoid compliance on the one hand, and a breach with the powers on the other. Thanks to Morone and Borromeo, however, he achieved his end. The council was dissolved on the 4th of December 1563, and its decrees and definitions confirmed by the pope (Jan. 26, 1564), who reserved to himself the sole right of interpretation. The decrees were immediately accepted by most of the Catholic states; only tardily, however, and with reservation by France and Spain. Various measures were taken for carrying the decrees into effect: residence was strictly enjoined; plurality of benefices prohibited; the Inquisition resumed, under the presidency of Ghislieri (afterwards Pius V.); a new edition of the Index published (1564); and the “Tridentine creed” promulgated (Nov. 13, 1564).

After the termination of the council Pius indulged his desire for ease and pleasure, to the great offence of the rigorists. A certain fanatic, Benedetto Accolti, brooding over the pope’s unworthiness, set out to combat the principle of the episcopate discovered and punished (1565). Pius fortified Rome, and contributed much to the embellishment of the city—among other works, the church of Sta Maria degli Angeli in the Baths of Diocletian; the Porta Pia; the Villa Pia in the Vatican Gardens; and the Palace of the Conservatori. He died on the 9th of December, and was succeeded by Pius V.

See Panvinio, continuator of Platina, De viis pontiff. rom. (a contemporary of Pius); Ciacionius, Vitae et res gestae summorum pontificum. rom. (Rome 1601–1602; also contemporary); T. Müller, Ds Konklave Pius IV. (Gotha, 1889; more comprehensive than the title suggests); Ranke, Popes (Eng. trans., Austin), i. 323 seq., 358 seq.; and v. Reumont, Gesch. der Stadt Rom. iii. 2, 534 seq., 730 seq. (T. F. C.)

PIUS V. (Michele Ghislieri), pope from 1566 to 1572, was born on the 17th of January 1504, in the Milanese. At the age of fourteen he became a Dominican monk. His austerite life, his vehemence in attacking heresy and his rigorous discipline as prior of several monasteries proved his fitness for the work of reform, and he was appointed inquisitor in Como, where his zeal provoked such opposition as to cause his removal (1556). The attempt of Caraffa, convinced of his value, straightforwardly sent him upon a mission to Lombardy, and in 1551 appointed him commissary-general of the Holy Office. When Caraffa became pope, Ghislieri was made bishop of Nepi and Sutri, cardinal (1557), and finally grand inquisitor, which office he discharged in a manner to make the name of “Fra Michele dell’ Inquisizione” a terror. In this office he was continued by Pius IV., whom, however, he repelled by his excessive severity, and antagonized by his censoriousness and obstinacy. But the movement with which he so fully identified was irresistible; and, after the death of Pius IV., the rigorists, led by Borromeo, had no difficulty in making him pope (Jan. 7, 1566).

Though pope, Pius did not cease to be a monk: his ascetic mode of life and his devotions suffered no interruption. Without delay he applied himself to the work of reform. Decrees and ordinances were issued with astonishing rapidity: the papal court was rid of everything unseemly, and became a model of sobriety; prostitutes were driven from the city, or confined to a certain quarter; severe penalties were attached to Sunday desecration; an animal horrid, clerked residence was enforced; conventuals were compelled to live in strict seclusion according to their vows; catherinechical instruction was enjoined. A new catechism appeared in 1566, followed by an improved breviary (1568), and an improved missal (1570). The use of indulgences and dispensations was restricted, and the penitential system reformed.

Pius was the avowed enemy of nepotism. One nephew, it is true, he made cardinal, but allowed him no influence: the rest of his relatives he kept at a distance. By the constitution Admonet nos (March 29, 1567), he forbade the reinstitution of fees that should revert to the Holy See, and bound the cardinals by oath to observe it. In March 1569 Pius ordered the expulsion of the Jews from the states of the Church. For commercial reasons they were allowed to remain in Rome and Ancona, but only upon humiliating conditions. In February 1571, the Umliaitis, a degenerate monastic order of Milan, was suppressed on account of its complicity in an attempt upon the life of the archbishop, Carlo Borromeo.

The election of Pius to the papacy was the enthronement of the Inquisition: the utter extinction of heresy was his darling ambition, and the possession of power only intensified his passion. The rules governing the Holy Office were sharpened; old charges, long suspended, were revived; rank offered no protection, but rather exposed its possessor to fiercer attack; none were pursed more relentlessly than the cultured, among whom many of the Protestant doctrines had found acceptance; princes and states withdrew their protection, and courted the favour of the Holy See by surrendering distinguished offenders. Cosmo de’ Medici handed over Pietro Carnesecchi (and two years later received in reward the title of grand duke, Sept. 1560); Venice delivered Guido Zanetti; Philip II., Bartolomé de Carranza, the archbishop of Mexico. With 1571 the Congregation of the Index was established and given such strictness introduced into the pursuit of heretical literature. The result was the flight of hundreds of printers to Switzerland and Germany. Thus heresy was hunted out of Italy: the only regret of Pius was that he had sometimes been too lenient. In 1567 Pius condemned the doctrines of Michael Baius, a professor of Louvain, who sought justification by faith, asserted the sufficiency of the Scriptures, and disparaged outward forms. Baius submitted; but his doctrines were afterwards taken up by the Jansenists.

The political activities of Pius were controlled by one principle, war upon the heretic and infidel. He spurred Philip II. on in the Netherlands, and approved the bloody work of Alva. He denounced all temporizing with the Huguenots, and commanded their utter extermination (ad interinccionem usque). While it cannot be proven that he was privy to the massacre of St Bartholomew, still his violent counsels could not fail to stir up the most savage passions. He exclaimed loudly against the emperor’s toleration of Protestantism, and all but wished his defeat at the hands of the Turks. He urged a general coalition against the Protestants, and when he failed in a sharper form, the bull In coena domini (1568), which was regarded by these very states as an attack upon their sovereignty. One of his cherished schemes was the invasion of England and the dethronement of Elizabeth, whom he excommunicated and declared a usurper (Feb. 25, 1570); but he was obliged to content himself with abetting plots and fomenting rebellions. He did, however, effect an alliance with Spain and Venice against the Turks, and contributed to the victory of Lepanto (Oct. 6, 1571).

Thus lived and wrought Pius, presenting “a strange union of singleness of purpose, magnanimity, austerity and profound religious feeling with sour bigotry, relentless hatred and bloody persecution” (Ranke). He died on the 1st of May 1572; and was canonized by Clement XI. in 1712.

See Ciacionius, Vitae et res gestae summorum pontificum. rom. (Rome, 1601–1602; a contemporary of Pius); Acta sanctorum, mayi. tom. i. pp. 616 seq., containing the life by Gabuzzio (1605), based on an earlier one by Catena (1586); Falloux, Hist. de St Pie V. (3rd ed., Paris, 1858), enolosgetic; Mendham, Life and Pontificate of St Pius V. (London, 1852), a bitter polemic. The life of Pius has also been written by Fuenmayor, Madrid, 1715; by Pietro Antonio Mauffe (Rome, 1712), and by T. M. Granello (Bologna, 1877). His letters have been edited by Catena (vide supra), Gobau (Antwerp, 1640), and a select number in a French translation, by de Potter (Paris, 1826). See also Hilliger, Die Wahl Pius V. zum Papste (Leipzig, 1891); Ranke, Popes (Eng. trans., Austin), i. 361 seq., 384 seq.; and von Reumont, Gesch. der Stadt Rom. iii. 2, 557 seq. (T. F. C.)

PIUS VI. (Giovanni Angelo Braschi), pope from 1775 to 1790, was born at Cesena, on the 27th of December 1717. After taking the degree of doctor of laws he went to Ferrara and became the private secretary of Cardinal Ruffo, in whose bishopric of Ostia and Velletri he held the post of uditore until 1753. His
skill in the conduct of a mission to the court of Naples won him the esteem of Benedict XIV., who appointed him one of his secretaries and canon of St Peter's. In 1758 he was raised to the prelature, and in 1766 to the treasurership of the apostolic chamber by Clement XIII. Those who chafed under his conscientious economies cunningly induced Clement XIV. to create him cardinal-priest of San Onofrio on the 26th of April 1773, a promotion which rendered him for the time innocuous. In the four months' conclave which followed the death of Clement XIV., Spain, France and Portugal at length dropped their objection to Braschi, who was after all one of the more moderate opponents of the anti-Jesuit policy of the previous pope, and he was elected to the vacant see on the 15th of February 1775.

His earlier acts gave fair promise of liberal rule and reform in the defective administration of the papal states. He showed discrimination in his benevolences, reprimanded Potenziani, the governor of Rome, for unsuppressed disorders, appointed a council of cardinals to remedy the state of the finances and relieve the pressure of imposts, called to account Nicolò Biscchi for the expenditure of moneys intended for the purchase of grain, reduced the annual reboursments by the suppression of several pensions, and adopted a system of counties for the encouragement of agriculture. The circumstances of his elevation, however, involved him in difficulties from the outset of his pontificate. He had received the support of the ministers of the Crown and the anti-Jesuit party upon a tacit understanding that he would continue the action of Clement, by whose brief Dominus ac redemptor (1773) the dissolution of the Society of Jesus had been pronounced. On the other hand the zelanti, who believed secretely inclined towards Jesuitism, expected from him some reparation for the alleged wrongs of the previous reign. As a result of these complications Pius was led into a series of half measures which gave little satisfaction to either party: although it is perhaps largely due to him that the order was able to escape shipwreck in White Russia and Silesia; at but one juncture did he even seriously consider its universal re-establishment, namely in 1792, as a bulwark against revolutionary ideas. Besides facing dissatisfaction with this temporizing policy, Pius met with practical protests tending to the limitation of papal authority. To be sure "Febronius," the chief German literary exponent of the old Gallican ideas, was himself led (not without scandal) to retract; but his positions were adopted in Austria. Here the social and ecclesiastical reforms undertaken by Joseph II. and his minister Kaunitz touched the supremacy of Rome so nearly that in the hope of staying them Pius adopted the exceptional course of visiting Vienna in person. He left Rome on the 27th of February 1782, and, though magnificently received by the emperor, his mission proved a fiasco; he was, however, able a few years later to curb those German archbishops who, in 1786 at the Congress at Ems, had shown a tendency towards independence. In Naples difficulties necessitating certain concessions in respect of feudal homage were raised by the minister Tannucci, and more serious disagreements arose with Leopold I. and Scipione de' Ricci, bishop of Pistoia and Prato, upon the questions of reform in Tuscany; but Pius did not see fit to condemn the offensive decrees of the synod of Pistoia (1786) which, in eight years had elapsed. At the outbreak of the French Revolution Pius was compelled to see the old Gallican Church suppressed, the pontifical and ecclesiastical possessions in France confiscated and an effigy of himself burnt by the populace at the Palais Royal. The murder of the republican agent, Hugo Basseville, in the streets of Rome (January 1793) gave new ground of offence; the papal court was charged with complicity by the French Convention; and Pius threw in his lot with the league against France. In 1796 Napoleon invaded Italy, defeated the papal troops and occupied Ancona and Loreto. Pius sued for peace, which was granted at Tolentino on the 10th of February 1797; but on the 28th of December of that year, in a riot created by some Italian and French revolutionists, General Duhour of the French embassy was killed and a new pretext furnished for invasion. General Berthier marched to Rome, entered it unopposed on the 13th of February 1798, and, proclaiming a republic, demanded of the pope the renunciation of his temporal authority. Upon his refusal he was taken prisoner, and on the 20th of February was escorted from the Vatican to Siena, and thence to the Certosa near Florence. The French declaration of war against Tuscany led to his removal to the custody of Parma, Piacenza, Turin and Grenoble to the citadel of Valence, where he died six weeks later, on the 26th of August 1799. Pius VII. succeeded him.

The name of Pius VI. is associated with many and often unpopular attempts to revive the splendour of Leo X. in the promotion of art and public works—the words "Magnificentia Pii VI. P. M." graven in all parts of the city, giving rise amongst his impoverished subjects to such satire as the insertion of a minute loan in the hands of Pasquin with that inscription beneath it. He is best remembered in connexion with the establishment of the museum of the Vatican, begun at his suggestion by his predecessor, and with an unpatriotic and expensive attempt to drain the Pontine marshes.

Pius VII. (Luigi Barnaba Chiaramonti), pope from 1800 to 1823, the son of Count Scipione Chiaramonti and the deeply religious Countess Ghini, was born at Cesena on the 14th of August 1740 (not 1742). After studying at Ravenna, at the age of sixteen he entered the Benedectine monastery of St Mary in his native town: here he was known as Gregorio. Immediately he was sent by his superiors to Padua and to Rome for a further course of studies in theology. He then held various teaching appointments in the colleges of his order at Parma and at Rome. He was created an abbot of his order by his relative Pius VI., who also appointed him bishop of Tivoli on the 16th of December 1782, and on the 14th of February 1785, because of excellent conduct of office, raised him to the cardinalate and the see of Imola. At the death of Pius VI. the conclave met at Venice on the 30th of November 1799, with the result that Chiaramonti, the candidate of the French cardinal-archbishop Mauroy, who was most skilfully supported by the secretary of the concordate Ezequiell, was elected pope on the 14th of March 1800. He was crowned on the 21st of that month; in the following July he entered Rome, on the 11th of August appointed Consalvi cardinal-deacon and secretary of state, and busied himself with administrative reforms.

His attention was at once directed to the ecclesiastical anarchy of France, where, apart from the broad schism on the question of submission to the civil constitution of the clergy, discipline had been so far neglected that a large proportion of the churches were closed, dioceses existed without bishops or with more than one, Jansenism and clerical marriage were on the increase, and indifference or hostility widely prevailed amongst the people. Encouraged by Napoleon's desire for the re-establishment of the Roman Catholic religion in France, Pius negotiated the celebrated concordat, which was signed at Paris on the 15th of July and ratified by Pius on the 14th of August 1801 (see Concordat). The importance of this agreement was, however, considerably lowered by the "articles organiques" appended to it by the French government on the 8th of April 1802. In 1804 Napoleon opened negotiations to secure at the pope's hands his formal consecration as emperor. After some hesitation Pius was induced to perform the ceremony at Notre Dame and to extend his visit to Paris for four months; but in return for these favours he was able to obtain from Napoleon merely one or two minor concessions. Pius, who arrived in Rome on the 16th of May 1805, gave to the college of cardinals a rose-coloured report of his experiences; but disillusionment was rapid. Napoleon soon began to disregard the Italian concordat of 1803, and himself decreed the dissolution of the marriage of his brother Jerome with Miss Patterson of Baltimore. The irritation between France and the Vatican increased so rapidly that on the 2nd of February 1808 Rome was
occupied by General Miolli; a month later the provinces of Ancona, Macerata, Fermo and Urbino were united to the kingdom of Italy, and diplomatic relations between Napoleon and Rome were broken off; finally, by a decree issued from Schönbrunn on the 17th of May 1809, the emperor united the papal states to France. Pius retaliated by a bull excommunicating the invaders; and, to prevent insurrection, Miolli—either on his own responsibility, as Napoleon afterwards asserted, or by order of the latter—employed General Radet to take possession of the pope's person. The palace on the Quirinal was broken open during the night of July 5th, and, on the persistent refusal of Pius to rescind the bull of excommunication and to renounce his authority, he was carried off, first to Grenoble, thence after an interval to Savonna on the Gulf of Genoa. Here he steadfastly refused canonical institution to the bishops nominated by Napoleon; and, when it was discovered that he was maintaining a secret correspondence, he was deprived of all books, even of pen and ink. At length, his nerves shattered by insomnia and fever, he was willing to give satisfactory oral assurances as to the intention of the French bishops.

In May 1812 Napoleon, on the pretext that the English might liberate the pope if he were left at Savonna, caused the aged and sick pontiff to be transported to Fontainebleau; the journey was so hard that on Mount Cenis Pius received the viaticum. Arriving safely, however, at Fontainebleau, he was lodged in a suite of regal magnificence to await the return of the emperor from Moscow. When Napoleon arrived, he entered into personal negotiations with the pope, who, on the 25th of January 1815, assented to a concordat so degrading that his conscience found no relief till the 24th of March, when, on the advice of the cardinal Paccia and Consalvi, he abrogated it; and on the 9th of May he proceeded to defy the emperor by declaring invalid all the official acts of the new French bishops. In consequence of the battle of Leipzig and the entry of the allied forces into France, Napoleon ordered in January 1814 that the pope be returned to Savona for safe keeping; but soon the course of events forced him to leave the city, and to give back the States of the Church. On the 19th of March Pius left Savonna, and was received with rejoicing at Rome on the 24th of May. While Consalvi at the Congress of Vienna was securing the restitution of nearly all the papal territory, reaction had full swing at Rome; the Jesuits were restored: the French legislation, much of which was of great social value, was repealed; the Index and the Inquisition were revived. On his return Consalvi conducted a more enlightened and highly centralized administration, based largely on the famous Motu proprio of 1816; nevertheless the finances were in a desperate condition. Discontent centred perhaps in the Carbonari, a Liberal secret society condemned by the pope in 1821. The chief triumphs of Consalvi were the negotiation of a series of valuable concordats with all the Roman Catholic powers save Austria. In the latter years of Pius's life royalty often came to Rome; the pope was very gracious to exiled kings and showed notable magnanimity toward the family of Napoleon. He was also a protecter of the arts, and in the city, including the Vatican, the greatest sculptors of the time, one of whom, the Protestant Thorwaldsen, prepared the tomb in which repose the remains of the gentle and courageous pontiff, who passed into rest on the 20th of August 1823.

His successor was Leo XII.

Both these last have good bibliographies. (W. W. R.)

Pius VIII. (Francesco Xavieri Castiglioni), pope from 1829 to 1830, who came of a notable family at Cingoli near Ancona, was born on the 20th of November 1761. He studied canon law at Rome, became vicar-general at Anagni and later at Fano, and in 1800 was appointed bishop of Montalto. Because he refused the oath of allegiance to the Napoleonic king of Italy he was carried captive to France; but in 1816 his steadfastness was rewarded by his being created cardinal-priest of Sta Maria in Trastevere; and this same year he was translated from the see of Montalto to that of Cesena. In 1821 he was made cardinal-bishop of Frascati, also grand penitentiary; and later he became prefect of the Congregation of the Index. In the conclave which followed the death of Leo XII, Castiglioni, the candidate of France, was elected pope on the 31st of March 1829. He avoided nepotism, abandoned the system of espionage employed by his predecessor, and published an encyclical condemning Bible societies and secret associations. He rejoiced over Catholic emancipation in England, recognized Louis Philippe as king of the French, and exhibited a pacific spirit in dealing with the problem of mixed marriages in Germany. Worn out with work, he died on the morning of the 1st of December 1830. His successor was Gregory XVI.
Italian policy. The problem of giving the people a due share in the government was one of peculiar difficulty in the papal states. It was not simply a question of adjusting the claims of monarch and subject: it was necessary, at the same time, to oust the clergy—who, till then, had held all the more important offices in their own hands—from their dominant position, or at least to limit their privileges. That the clerical character of the administration could not be indefinitely retained was plain enough, it would seem, to any clear-thinking statesman: for, since the restoration of the papal state in 1814, the pernicious effects of this confusion of the spiritual and the secular power could no longer be denied. But Pius IX. lacked the courage and perspicacity to draw the inevitable conclusions from these premises; and the higher clergy at Rome were naturally opposed to a policy which, by laizicing the administration, would have deprived them of the power and privileges they had so long enjoyed. In these circumstances it is not surprising that the pope, while making concessions to his people, did so with reservations which, so far from restoring peace, served only to aggravate the turmoil.

By a motu proprio of the 2nd of October 1847 the government of the city of Rome was reorganized and vested in a council of 24 members, chosen by the pope and the consistory. But the pope reserved to himself the right of nominating the first members, and the new senate was only later to have the right of filling up vacancies by co-optation. The institution of a state council (consulta) was announced on the 19th of April 1847; and on the 14th of October it was called into existence by a motu proprio. It consisted of 24 councillors, who were to be selected from the pope by a list of candidates to be submitted by the provincial assemblies. A cardinal and one other prelate were to be at its head. The consulta was to be divided into four sections, dealing with (1) legislation, (2) finance, (3) internal administration, (4) the army and public works. Matters of importance were, however, to be submitted to the College of Cardinals, after being debated in the consulta. A motu proprio of the 29th of December altered the constitution of the municipal council. Nine mutually independent ministries were formed, and the principle of the responsibility of the ministers was established: but all the positions were filled by clerics.

The agitation for constitutional government was urgent in the demand for further concessions; but they came too late. On the 12th of February a proclamation of the pope transferred three portfolios to the laity; but the impression produced by the news of the revolution in Paris nullified the effect. At the formation of the Autonelli ministry (March 11), only the three departments of foreign affairs, finance, and education, were reserved by the clergy; while the remaining six were entrusted to laity. On the 14th of March 1848 Pius took the last step, and published a constitution (Fundamental Statute for the Secular Government of the States of the Church). Two chambers were to be formed. The first (alto consiglio) consisted of members nominated for life by the pope; the second, of a hundred elected deputies. The laws adopted by these two chambers had to undergo the scrutiny of the College of Cardinals, before being submitted to the pope for his assent or rejection. Ecclesiastical, or ecclesiastico-political, affairs were exempted from the jurisdiction of the parliament; which was further required to abstain from the enactment of laws conflicting with the discipline of the Church, and from criticism of the diplomatic and religious relations of the Holy See with foreign powers.

The utility of this constitution was never tested; for the demand for an extension of popular rights was now eclipsed by a still more passionate aspiration towards the national unity of Italy. This nationalist movement at once took head against Austria. On the 18th of March the revolution broke out in Milan, and King Albert of Sardinia undertook the conduct of the war against the emperor. When news of the events at Milan reached Rome the populace was swept away in a whirlwind of enthusiasm: the Austrian embassy was mobbed; the imperial arms, surmounting the main gate of the palace, were torn down; and great troops of volunteers clamoured to be led against Austria. Pius was carried away at first on the flood-tide of excitement, and seemed, after his proclamation of the 30th of March, on the point of conferring his blessing upon the war against Austria. But the course of political events during the next few weeks damped his ardour. When, on the 20th of April, in his allocation to the cardinals, he proclaimed the papal neutrality, the Romans received his vacillation as a sign of treachery; and the storm, precluded from discharging its fury on Austria, broke over his head. When the ministry in power resigned office on the 1st of May, the Mamiani administration was formed, only one cleric being included. Mamiani himself, whose writings were on the Index, had little sympathy with the pope, and did all that was possible to complete the secularization of government in the States of the Church. He received his dismissal on the 1st of August, and was followed by Count Fabbrini, then by Count de Rossi, who made the last attempt to restore order by a moderate liberal policy. On the 15th of November, as he was about to open the Chambers, he was assassinated on the staircase leading to the hall of session. A state of anarchy ensued. Armed bands gathered before the Quirinal, and attempted to storm it. To avoid further bloodshed the pope was compelled to assent to the formation of a radically democratic ministry under Gisletti. The Swiss, who had come to the papal garrison, were sent home; and the protection of the pontiff was transferred to the civil militia; in other words, Pius IX. was a prisoner. On the evening of the 24th of November he contrived by the aid of the French and Bavarian ambassadors—the duc d'Harcourt and Count Spaur—to leave the palace unobserved, in the dress of a common priest, and to reach Gaeta in the kingdom of Naples. From this refuge he issued a brief on the 27th of November, protesting against the sacrefice practised on himself, declaring all actions forced upon him null and void, and appointing a commission to carry on the government in his absence. Since the Chamber declined to recognize this step, and the pope was equally resolute in refusing to hold any intercourse with the deputation which it despatched to him, a supreme Giunta was provisionally created by the Chamber on the 11th of December to discharge all the functions assigned to the executive power by the constitution. On the 17th of the same month Pius made a public protest; and, as soon as the elections for a national assembly were announced, he forbade any participation in them, menacing the males, in the name of the papal Chambers (Jan. 1, 1849). The elections, however, were held; and on the 9th of February the constituent assembly decreed, by 142 votes to 23, the erection of a Roman republic. Pius answered by a protest dated the 14th of February. All the ecclesiastical property of the Roman state was now declared to be vested in the republic; convents and religious edifices were requisitioned for secular purposes; benevolent institutions were withdrawn from clerical influence; and church establishments were deprived of the right to realize their possessions. In the beginning of December Pius had already appealed to the European powers for assistance; and on the 7th of February 1849 it was resolved in the Consistory to approach officially France, Austria, Spain and Naples, with a view to their armed intervention. The French republic, under the presidency of Louis Napoleon, was the first state to throw troops into Italy. On the 24th of April General Oudinot appeared before Civita Vecchia; only to be defeated at first by Garibaldi. But, after receiving reinforcements, he prosecuted the war successfully, and made his entry into Rome on the 3rd of July, in the early part of May an Austrian army advanced into the north of the papal states. On the 14th of July Oudinot proclaimed the restoration of the pontifical dominion; and, three days later, Pius IX. issued a manifesto entrusting the government to a commission appointed by himself.

On the 12th of April 1850 Pius returned to Rome, supported by foreign arms, embittered, and hostile henceforward to every form of political liberalism or national sentiment. In Gaeta he had mentally cut himself loose from all ideas of progress, and had thrown himself into the arms of the Jesuits. His subsequent policy was stamped by reaction. Whether it might have been possible to avoid the catastrophe of 1870 is a difficult question. But there can be no question whatever that the policy which
Pius now inaugurated, of restoring the old pre-revolutionary conditions, sealed the fate of the temporal dominion of the papacy. He made no attempt to regain the estranged affections of the populace, and took no measures to liberate himself and his subjects from the incubus of the last few years. He even sought to exact vengeance for the events of that period: the state officials, who had compromised themselves, lost their offices; and all grants in aid were forfeited if the recipients were discovered by the secret commissions (consigli di censura) to have taken part in the revolutionary movement. The tribunals extorted declarations on the part of witnesses by flogging, deprivation of food, and, like methods of torture. In many cases the death sentence was executed at their instance, though the guilt of the accused was never established. The system of precautionary arrest, as it was termed, rendered it possible for any man to be thrown into prison, without trial and without verdict, simply on the ground that he lay under suspicion of plotting against the government. The priests, who usurped the judicial function, displayed such cruelty on several occasions that officers of the Austrian army were compelled to record a protest. The consequence of these methods was that every victim—innocent or guilty—ranked as a martyr in the estimation of his fellow-citizens. A subsidiary result was the revival of brigandage, which found a suspicious degree of support among the people. Corruption was rampant among the officials; the police were accused of illicit bargaining with criminals; and nothing but contempt was entertained for the papal army, which was recruited from the dregs of humanity. To this was added a disastrous financial administration, under which the efficiency and credit of the country sank to appalling depths. The system of taxation was calculated with a view to relieving the Church and the clergy, and imposing the main burden upon the laity. In this department the family of Cardinal Antonelli seems to have played a fatal part. The secretary of state was born in humble circumstances: when he died he left a fortune of more than 100,000,000 lire, to which a daughter succeeded in establishing her claim. His brother Felippo was president of the Roman Bank, and his brother Luigi the head of the Annona—an office created to regulate the import of grain. The pope himself had neither the will nor the power to institute searching financial reforms: possibly, also, he was ignorant of the facts.

The mismanagement which obtained in the papal dominions could not escape the observation of the other powers. As early as the Congress of Paris in 1856 the English ambassador, Lord Clarendon, had directed an annihilating criticism against the government of the pontiff; and a convincing proof of the justice of his verdict was given by Pius himself, in his treatment of the famous Mortara case. A Jewish boy of this name had been torn from his parents in Rome and the rite of baptism performed on him without their knowledge or consent. The pope flatly refused to restore the "Christian" to his Jewish parents, and turned a deaf ear both to the protest of public opinion and the diplomatic representations of France and England. The sequel to this mode of government was that the growing embitterment of the subjects of the Church came to be sympathized with outside the bounds of Italy, and the question whether the secular authority of the papacy could be allowed to continue became a much-debated problem. Even the expression of the doubt was symptomatic. In 1859 appeared an anonymous brochure, Le Pope e le congreg, composed by Laguernonnire, the friend of Napoleon III., in which it was proposed to ensure the pope "un revenu considerable" and the city of Rome, but to turn him of a political task to which he had been torn from his munificent patron. Pro causa italica ad episcopos catholicaos, was published in Florence, advocating the ecclesiastico-political programme of Cavour; and the pope was horrified when he discovered that it came from the pen of Passaglia, the professor of dogmatic theology. In spite of all, the national idea gained strength in Italy, and the movement towards unity found powerful champions in King Victor Emmanuel of Sardinia and his great statesman Cavour. Free scope was given when the understanding between the two powers protecting the papal state—France and Austria—broke down. So soon as Napoleon and Cavour had come to an agreement war ensued, France and Sardinia being ranged against Austria (1859). The result was that Austria lost the greater part of her Italian possessions, while the pope also forfeited two-thirds of his dominions. By the war of 1866, in which Italy fought on the Prussian side, Victor Emmanuel gained Venice in addition; so that the States of the Church now formed the last remaining obstacle to complete national unity. In September 1864, France—who had been the protectress of these states since 1849—had concluded a treaty with Victor Emmanuel, undertaking to withdraw her garrison from Rome if two years time; while, on his part, the king agreed to abstain from any attack on the papal dominions, and to guarantee the safety of the pope and the "pairirioninmum Ferei." The emperor Napoleon had, in point of fact, recalled his troops in 1866; but in 1867, when Garibaldi crossed the frontiers of the papal state at the head of his volunteers, he declared the treaty violated and again threw his regiments into Rome. Three years later the time came when he could employ his arms more advantageously elsewhere, and after the outbreak of the war with Germany Rome was evacuated. The news that the French Empire had fallen produced an electrical effect in Italy; the Italian parliament called on the king to occupy Rome; on the 8th of September Victor Emmanuel crossed the borders; and on the 20th of September the green-white-and-red of the tricolour floated over the Capitol. The protests of Pius IX. remained unheeded, and his attempts to secure another foreign intervention met with no success. On the 2nd of October Victor Emmanuel instituted a plebiscite in Rome and the possessions of the Church to decide the question of annexation. The result of the suffrage was that 153,681 votes were given in favour of union with Italy, and 1507 against the proposed incorporation; that is to say, only the direct dependants of the Vatican were opposed to the change. The papal state was now merged in the kingdom of Italy, which proceeded to define its diplomatic relations with the Holy See by the law of the 13th of May 1871 (see Italy: History).

In his capacity as head of the Church, Pius IX. adhered to the principles of the Ultramontanist party, and contributed materially to the victory of that cause. The political reaction which followed the revolutionary era in most quarters of Europe offered a favourite soil for his efforts; and in several countries he found it possible to regulate the relations between Church and state from the standpoint of the curia. In 1853 he concluded a concordat with Queen Isabella II. of Spain, proclaiming Roman Catholicism the sole religion of the Spanish people, to the exclusion of every other creed (art. 1); and we find the same provision in another concordat with the Southern American republic of Ecuador (1862). A third concordat, negotiated with the emperor Francis Joseph I. of Austria (1857), entrusted the supervision of schools and the censorship of literature to the clergy, recognized the canon law, and repealed all secular legislation conflicting with it. France came into line with the wishes of the pope in every respect, as Napoleon needed clerical support in his political designs. Even in Germany he found no resistance; on the contrary, he was able to secure advantageous compacts from individual states (Hesse, 1854; Wurttemberg, 1857). In fact, the growing tendency to romanize Catholicism—to bring it, that is to say, into close connexion with Rome, and to a state of dependency on the guidance and instructions of the curia—made special progress in Germany.

Among the most important acts of Pius IX. must be counted his protestation of the dogma of the immaculate Conception of the Virgin Mary, by the bull Ineffabilis Deus, on the 8th of December 1854. In this bull the preservation of Mary from every stain of hereditary sin, in the first moment of her conception, was declared to be a divinely revealed truth, which consequently demanded universal acceptance (see IMMACULATE CONCEPTION). By this means a view, which till then had been no more than a pious belief, was elevated into a dogma to be held de fide; though grave doubts on the subject had always been entertained, even in the midst of the Church itself. For the inner life of that
PIVOT—PIZARRO

Church this solution of the controversy was of great significance, and created a desire for further dogmatic decisions on the Virgin Mary—her resurrection and ascension. But the procedure of Pius IX, proved of far-reaching importance from another point of view. True, he had taken the opinion of the bishops on the subject, and had received the assent of a large majority; none the less, the verdict was pronounced by himself alone, not by an ecumenical council. Thus, by arrogating the function formerly exercised by the ecumenical council, he virtually laid claim to the infallibility which had always been regarded as inherent only in the doctrinal pronouncements of such a council: in other words, he availed himself of a privilege not accorded to him till the 18th of July 1870.

Though the Marian dogma of 1854 received, with very few exceptions, an enthusiastic welcome in Roman Catholic circles, another measure of the pope, ten years later, excited a painful sensation even among the orthodox members of the Church. As reigning sovereign of the papal states Pius IX. had passed through a “liberal period”: as head of the Church, he had never been liable to attacks of liberalism. Nevertheless, his return from exile left its mark on his spiritual administration. For from this period onwards he deliberately and stubbornly set his face against the influence of modernism on ecclesiastical life; showed his displeasure at and distrust of the scientific theology and philosophy which marked a moderate advance (Günther, Frohnhämer and Dollinger); and, entrenched in the strong hold of mediaeval legalism, he transformed the foundations of the new order of society, and the changes in the relationship between Church and state, which obtained in most countries of Europe since the French Revolution. After long and careful consultation, the adverse criticisms which he had expressed on various occasions were published on the 8th of December 1864, together with the encyclical Quanta cura, under the title Syllabus complectens praecipuos nostrae aetatis errores (see SYLLABUS). In this Pius claimed for the Church the control of all culture and all science, and of the whole educational system. He rejected the liberty of faith, conscience and worship enjoyed by other creeds; and bade an easy farewell to the idea of tolerance. He claimed the complete independence of the Church from state control; upheld the necessity of a continuance of the temporal power of the Roman See; and finally, in the last clause, declared that “the pontiff neither can be nor ought to be reconciled with progress, liberalism and modern civilization.”

The publication of this syllabus created a profound impression: for it declared war on modern society, and committed the papacy to the principles of Ultramontanism (q.v.). But, as any attempt to translate its precepts into practice would entail a disastrous collision with existing rights as established by law, Roman Catholic circles have frequently shown a tendency to belittle the significance of the manifesto and to deny that its rules are absolutely binding. But these well-meant explanations, however comprehensible, are refuted by the unequivocal pronouncements of Pius IX., Leo XIII., and many recognized ecclesiastical authorities—e.g. Cardinal Manning, archbishop of Westminster, who described the syllabus as an emanation from the highest doctrinal authority in the Church.

The zenith of Pius’s pontificate was attained on the 18th of July 1870 when the Vatican council proclaimed the infallibility of the pope and the universality of his episcopate, thus elevating him to a pinnacle which none of his predecessors had reached and at the same time fulfilling his dearest wish. That, personally, he laid great stress on the acceptance of the dogma, was a fact which he did not attempt to conceal during the long preliminary deliberations of the council; and his attitude was a not inconsiderable factor in determining its final resolutions. But the loss of the papal states, immediately afterwards, was a blow from which he never recovered. Whenever he brought himself to speak of the subject—and it was not rarely—he repeated his protest in the bitterest terms, and, to the end of his days, refused to be reconciled with the “sacriligious” king of Italy. When, in Germany, the situation created by the Vatican council led to the outbreak of the Kulturkampf, Pius IX. failed to display the tact peculiar to his successor. For, in the encyclical Quod numquam (Dec. 5, 1875), he took the rash step of declaring invalid the Prussian laws regulating the relationship between Church and state. The only result being that the feud was still further embittered.

In these later years the dark days of his “captivity” were amply compensated by the proofs of reverence displayed by Roman Catholic Christianity, which accorded him magnificent ovations as his period of jubilee began to fall due. The twenty-fifth anniversary of his pontificate was celebrated with great splendour on the 16th of June 1871; for he was the first pope who had thus reached the traditional “years of Peter.” In 1872 his 80th birthday gave occasion for new demonstrations; and 1875 was a so-called “year of jubilee.” Finally, in 1877, the fifty years of his priesthood were completed: an event which brought him innumerable expressions of loyalty and led to a great manifestation of devotion to the Holy See from all the Roman Catholic world. On the 7th of February 1878 Pius IX. died. His successor was Leo XIII.

Pius X. (Giuseppe Sarto), elected pope in 1903, was born on the 2nd of June 1853, of humble parents, at the little town of Rieti in the province of Treviso, Italy. He studied theology at the episcopal seminaries of Treviso and Padua, and was ordained priest in 1878. For seventeen years he acted as parish priest at various small places in Venetia, until in 1875 he was appointed canon of the cathedral and superior of the seminary at Treviso. In 1882 he was raised to the rank of bishop, but in 1884, on the death of his uncle, Pius IX, he was created cardinal, and on 15th June 1893 was made a cardinal, and three days later was nominated patriarch of Venice. In Venice he made himself very popular owing to his piety, his simplicity and geniality, and by his readiness to act in harmony with the Italian government. He succeeded Leo XIII. in his election to the papal chair on the 4th of August 1903. (See Papacy, ad fin.)

PIVOT (Fr. pivot; probably connected with Ital. piovo, peg, pin, diminutive of pivo, pipa, pipe), that on which something turns, specifically a metal pointed pin or short shaft in machinery, such as the end of an axle or spindle. The term occurs frequently in combination with other words, chiefly in technical usage, e.g. “pivot-gearing,” for a system of gearing in machinery which admits of the shifting of the axis of a driving wheel, so that the power may be communicated in various directions.

PIZARRO, FRANCISCO (c. 1471 or 1475–1541), discoverer and conqueror of Peru, was born at Trujillo in Estremadura, Spain, about 1471 (or 1475). He was an illegitimate son of Gonzalo Pizarro, who as colonel of infantry afterwards served in Italy under Gonsalvo de Cordova, and in Navare, with some distinction. Of Pizarro’s early years hardly anything is known; but he appears to have been poorly cared for, and his education was neglected. Shortly after the news of the discovery of the New World had reached Spain he was in Seville, and thence found his way across the Atlantic. There he is heard of in 1510 as having taken part in an expedition from Hispaniola to Urabá.
PIZZICATO—PLACENTA

under Alonzo de Ojeda, by whom he was entrusted with the charge of the unfortunate settlement at San Sebastian. He accompanied Balboa (whom he afterwards helped to bring to the block) in the discovery of the Pacific; and under Pedrazas d'Avila he received a repartimento, and became a cattle-farmer at Panama. Here in 1532 he entered into a partnership with a priest named Hernando de Luque, and a soldier named Diego de Almagro, for purposes of exploration and conquest towards the south. Pizarro, Almagro and Luque afterwards renewed their compact in a more solemn and explicit manner, agreeing to conquer and divide equally among themselves the opulent empire they hoped to reach. Explorations were then undertaken down the west coast of South America, in which Pizarro, though left for months with but thirteen followers on a small island without ship or stores, persisted till he had coasted as far as about 6° S. and obtained distinct accounts of the Peruvian Empire. The governor of Panama showing little disposition to encourage the adventurers, Pizarro resolved to apply to the sovereign in person for help, and with this object sailed from Panama for Spain in the spring of 1538, reaching Seville in early summer. Charles V. was won over, and on the 26th of July 1539 was executed at Toledo the famous capitacion, by which Pizarro was upon certain conditions made governor and captain-general of the province of New Castile for the distance of 200 leagues along the newly discovered coast, and invested with all the authority and prerogatives of a vicaroy, his associates being left in wholly secondary positions. One of the conditions of the grant was that within six months Pizarro should raise a sufficiently equipped force of two hundred and fifty men, of whom one hundred might be drawn from the colonies; as he could not make up his due complement he sailed clandestinely from San Lucar in January 1540. He was afterwards joined by his brother Hernando with the remaining vessels, and when the expedition left Panama in January of the following year it numbered three ships, one hundred and eighty men, and twenty-seven horses. The subsequent movements of Pizarro belong to the history of Peru (q.v.). After the final effort of the Incas to recover Cuzco in 1535-37 had been defeated by Diego de Almagro, a dispute occurred between him and Pizarro respecting the limits of their jurisdiction. This led to battle; Almagro was defeated (1538) and executed; but his supporters conspired and, assassinated Pizarro on the 26th of June 1541.

PIZZICATO (from Ital. pizzicare, to pluck or twitch), a term in music for a direction to the players of stringed instruments, that the passage so marked is to be played by plucking the strings with the fingers instead of using the bow.

PIZZO, a seaport of Calabria, Italy. In the province of Cosenza, 72 m. by rail N.E. of Reggio, situated on a steep cliff overlooking the Gulf of Santa Eufemia, 377 ft. above sea-level. Pop. (1901), 972. It has an old castle, in which Joachim Murat, ex-king of Naples, was shot on the 13th of October 1815. The people engage in tunny and cod-fishing. In 1783 the town was almost destroyed by an earthquake, and it suffered some damage from the same cause in 1905.

PLACARD (15th cent. Fr. placart, from placoire; mod. plaquer, to plaster), a bill or poster pasted or affixed to a wall or in any prominent position for the purpose of giving notice to the public of a proclamation, police or other regulations, or of forthcoming events or the like.

PLACE (through Fr. from Lat. platea, street; Gr. πατρίς, wide), a definite position in space, whether of limited or unlimited extent, situation or locality; also position in a series or rank; or an office, or employment, particularly one in the service of a government. Special applications are to an open space in a town, a group of buildings, row of houses, or as the name of a residence or manor-house. In certain cases this latter use accounts for the occurrence of parts of a town being known as Place, e.g. Ely Place in London, formerly the site of the town residence of the bishops of Ely. A "place of arms" (Fr. place d'armes), in fortification, means the wide spaces (suitable for the assembly of troops for a sortie) made by the salients and re-entrants of the covered way. The phrase is also used in a strategic sense to express an entrenched camp or fortress in which a large army can be collected under cover previous to taking the field.

PLACENTA (Lat. for a cake), in anatomy, the organ by which the embryo is nourished within the womb of its mother. When the young one is born the placenta and membranes come away as the "afterbirth." In human anatomy the organ is a circular disk about seven or eight inches in diameter and one and a quarter inches in thickness at its centre, while at its margin it is very thin and is continuous with the foetal membranes. It weighs about a pound.

In order to explain the formation of the placenta it is necessary to encroach to some extent on the domain of physiology. Before each menstrual period, during the child-bearing age of a woman, the mucous membrane of the uterus hyperplrophises, and, at the period, is cast off and renewed, but if a fertilized ovum reaches the uterus the casting off is postponed until the birth of the child. From the fact that the thickened mucous membrane lining the interior of the uterus is cast off so late, it is spoken of as the "decidua." The fertilized ovum, on reaching the uterus, sinks into and embeds itself in the already prepared decidua, and, as it enlarges, there is one part of the decidua lying between it and the uterine wall ("decidua vera" or "basalis"), one part stretched over the surface of the enlarging ovum ("decidua reflexa" or "capsularis") and one part lining the rest of the uterus ("decidua vera") (see fig. 1).

From A. H. Young and A. Robison, in Cunningham's Text-Book of Anatomy.

---

**Fig. 1.** Diagram representing a very young human ovum almost immediately after its entrance into the decidua, and whilst the place of its entrance is still covered with a plug of fibrin. The ectoderm has already proliferated and embraced spaces which contain maternal blood and are continuous with the maternal blood-vessels.

It is the decidua basalis which is specially interesting in considering the formation of the placenta. That part which is nearest the ovum is called the "stratum compactum," but farther away the uterine glands dilate and give a spongy appearance to the mucous membrane which is the particular layer of the name of "stratum spongiosum." Processes grow out from the surface of the ovum which penetrate the stratum compactum of the decidua basalis and capularis and push their way into the enlarged maternal blood sinuses; these are the chorionic villi. Later, the "allantoic" or "abdominal stalk" grows from the mesoderm of the hind end of the embryo into the chorionic villi which enter the decidua basalis, and in these blood-vessels pass which push their way into the maternal blood sinuses. Eventually the original walls of these sinuses are separated from the same by the false amnion, disappear, and nothing now separates the maternal from the foetal blood except the delicate walls of the foetal vessels covered by some nucleated noncellular tissue, known as syncyitis, derived from the chorionic epithelium, so that the embryo is able to take its supply of oxygen and materials for growth from the blood of its mother and to give up carbonic acid and excretery matters. It is the gradual enlargement of the chorionic villi in the decidua basalis together with the intervillous maternal blood sinuses that forms the placenta; the decidua capularis and vera eventually become pressed
PLAGIARISM—PLAGIOCLASE

Together as the embryo enlarges, and then, as pressure continues, atrophy. The allantoic stalk elongates enormously, and in its later stages contains two arteries (umbilical) and only one vein (owing to the obliteration of the right one) embedded in some loose connective tissue known as Wharton's jelly. At first the stalk of the yolk-sac is quite distinct from this, but later the two structures become bound up together (see fig. 2), after which they are known as the umbilical cord. A distinction must be made between the allantoic stalk and the allantois; the latter is an entodermal outgrowth from the hind end of the mesoderm or primitive alimentary canal, which in the human subject only reaches a little way toward the placenta. The allantoic stalk is the mass of mesoderm containing blood-vessels which is pushed in front of the placenta and, as has been shown, reaches and blends with the decidua basalis to form the placenta.

For further details see Quain's Anatomy, vol. i. (London, 1868); and, for literature, O. Hertwig's Handbuch der Entwickelungslehre (Jena).

Comparative Anatomy.—If the placenta is to be regarded as a close union between the vascular system of the parent and embryo, the condition may be found casually scattered throughout the phylum of the Chordata. In such a very lowly member of the Placenta, an ovum has a great deal of yolk, and the young, born in a very immature condition, finish their development in the mother's pouch; but although these mammals have no allantoic placenta there is an intimate connection between the walls of the yolk-sac and the uterine mucous membrane, and so an umbilical or omphalo-placenta exists. The name Aplacentalia therefore only means that they have no allantoic placenta. Among the Placentalia, the umbilical and allantoic placenta are sometimes coexist for some time, as in the case of the hog, in which the allantois is a blind pouch. In most of the lower placentals the allantois is much more developed than in man, and the most primitive type of placenta is that in which yolk are formed over the whole surface of the chorion projecting into the decidua of the tubular cornu of the uterus. This is known as a diffuse placenta, and is met with in the pangolin, pig, hippopotamus, camel, cheetah, horse, rhinoceros, tapir and whale. When the villi are collected into a number of round tufts or cotyledons, as in most ruminants, the type is spoken of as a cotyledonous placenta, and an intermediate stage between this and the last is found in the giraffe.

In the Carnivora, elephant, procapric (Hyrax) and aard vark (Orycteropus), there is a zonary-placenta which forms a girdle round the embryo. In bats and lemurs the placenta is dome-shaped, while in rodents, insectivores and bats, it is a ventral disk or closely applied pair of disks, thus differing from the dorsal disk of the ant-eater, armadillo and higher Primates, which is known as the metadosal or placenta. It thus be seen that the form of the placenta is not an altogether trustworthy indication of the systemic position of its owner. In the diffuse and cotyledonous placenta the villi do not penetrate very deeply and at the decidua simply withdrawn, the decidua being left behind in the uterus, so that these placentae are spoken of as non-decidual while other kinds are deciduate.

(F. G. P.)

PLAGIARISM, an appropriation or copying from the work of another, in literature or art, and the passing off of the same as original or without acknowledgment of the real authorship or source. The Lat. plagiarus meant a kidnapper, stealer or abductor of a slave or child, though it is also used in the modern sense of a literary pilfer or purloiner by Martial (I. 53, 9). The word plagiarism is used in the Digest of the offence of kidnapping or abduction, and the ultimate source is probably to be found in plagia, net, snare, trap, cognate with Gr. πλαγέω, to weave, plait. The idea of plagiarism as a wrong is comparatively modern, and has grown up with the increasing sense of property in works of the intellect. (See Copyright.)

PLAGIOCLASE, an important group of rock-forming minerals, constituting an isomorphous series between albite, or soda-felspar, and anorthite, or lime-felspar. Intermediate members are thus soda-lime-felspars, which in their crystallographical, optical and other physical characters vary progressively with the chemical composition between the two extremes albite (NaAlSiO₃) and anorthite (CaAl₂Si₂O₆). This variation is continuous in the series, and the names are used only within certain arbitrary limits, viz.: Albite, Ab (= NaAlSiO₃); Oligoclase, AbAn to AbAn; Andesine, AbAn to AbAn; Labradorite, AbAn to AbAn; Bytownite, AbAn to AbAn; Anorthite, AbAn to CaAl₂Si₂O₆. All the members of the series crystallize in the anorhistic (triclinic) system. They possess a perfect cleavage parallel to the basal pinacoid P (001) and a somewhat less pronounced cleavage parallel to the pinacoid M (010). The angle between these two cleavages varies from 86° 24' in albite to 85° 50' in anorthite. It was on account of the oblique angle between the cleavages that A. Breithaupt in 1847 gave the name plagioclase (Gr. πλαγιός, oblique, and κλαίω, to cleave) to these felspars, to distinguish them from the orthoclase felspar in which the corresponding cleavage angle is a right angle. It should be noted that the potash-and potash-soda-felspars, microcline (q.v.) an anorthocor, though also anorhistic, are not included in the plagioclase series of soda-lime-felspars. Crystals are from A. H. Young and A. Robinson, in Cunningham's Text-Book of Anatomy.

Fig 2.—Diagram. Later stage in the development of the placenta, showing the relations of the foetal villi to the placental sinuses, the fusion of the amnion with the inner surface of the chorion, and the thinning of the fused decidua capsularis and vera. In Amphibia as salpa, a placenta is formed, and the embryo is nourished within the body of its parent. In some of the viviparous sharks, e.g. the blue shark (Carcharias), the yolk-sac has ridges which fit into grooves in the wall of the oviduct and allow an interchange of materials between the maternal and foetal blood. This is an example of an umbilical placenta. In the viviparous bennies (Zoarcus viviparus), among the teleostean fishes, two or three hundred young are nourished in the hollow ovary, which develops villi secreting nutritive material. Among the Amphibia the alpine salamander (Salamandra alpina) nourishes its young in its oviducts until the gilled stage of development is past, while in the reptilia the young of a viviparous lizard (Seps chalcides) establishes a communication between the yolk-sac anteriorly and the allantois posteriorly, on the one hand, and the walls of the oviduct on the other. In this way both an umbilical and an allantoic placenta are formed.

The mammals are divided into Placentalia and Aplacentalia; in the latter group, to which the monotremes and most marsupials
usually tabular in habit, parallel to the plane \( M \), as shown in the accompanying figure; sometimes, however, they are flattened parallel to \( P \), this being a characteristic habit of the plagioclase variety of albite; microlite crystals forming the ground-mass of volcanic rocks are usually elongated in the direction of the edge between \( P \) and \( M \).

Twinned is an important character, which is almost invariably present and affords a ready means of distinguishing the plagioclases from other felspars. Most frequent is the twinning according to the "albite law" with \( M \) as twin-plane. One half of the twin is turned through 180° from the normal to this plane and the two portions are united along the same plane (for figures of twinned crystals see ALBITE). The basal planes of the two portions incline to each other at a small re-entrant angle of 7° 12' in albite and 8° 20' in anorthite. This twinning is usually polysynthetically, being many times repeated, and giving rise to numerous thin lamellae, which are the cause of fine striations on the cleavage planes \( P \) and parallel to the edge \( P M \), so characteristic of the plagioclases as seen in hand specimens. Viewed in polarized light, thin sections of twinned crystals show a very characteristic banded structure parallel to \( M \). A second twinning law is known as the "pericline" because of its frequent occurrence in pericline. Here the axis of rotation is the edge \( P \) (the crystallographic axis \( b \)) and the plane of composition is the "rhombic section"; the latter is a plane which intersects the prism faces \( T \) and \( L \) in a rhombic form; it is a possible face of the crystal, and its position varies in the different species. In addition to being twinned according to these two laws, plagioclase may also be twinned on the Carlsbad-, Baveno- and Manebach-laws, as in orthoclase (\( P P \)).

The optical characters of the plagioclases have been the subject of much study, since they are of great value in determining the constituents of rocks in this section under the microscope. The mean indices of refraction and the angles of extinction on the cleavages \( P \) and \( M \) are given in the accompanying table. (The meaning of the + and - directions will be seen from the figure, where the angle + \( P \) is taken from left to right, i.e. the angle between the normals to the faces lettered \( P \) and \( M \) is less than 90°.) The extinction angles on other faces, or in sections of known orientation in the crystal, also give constants of determinative value: for instance, in sections perpendicular to the plane \( P \) the extinction which in crystals twinned according to the albite-law are symmetrical with respect to this plane. The maximum value is given in the table. Not only do the directions of extinction (axes of light-elasticity) vary in the different species, but also the optic axial angle, so that while albite is optically positive, anorthite is negative, and a member near anorthite has an axial angle of 90°. The figures seen in convergent polarized light through the \( P \) and \( M \) cleavages are characteristic of the different species. A detailed summary of the optical characters and the employment in discriminating the several members of the plagioclase series is given by H. Rosenbusch, Mikroskopische Physiographie der Mineralien und Gesteine (4th ed. Stuttgart, 1905).

The plagioclases occur as primary constituents of igneous rocks of almost every kind, and are also frequent as secondary minerals in metamorphic rocks. Albite and oligoclase are more characteristic of acidic rocks, whilst the basic members at the anorthite end of the series are characteristic of rocks containing less silica. The composition may, however, vary even in the same crystal, zoned crystals with half or less anorthite being successively more and more acid towards the exterior being common.

For further particulars respecting individual species and their modes of occurrence see ALBITE; ANDESINE; ANORTHITE; BYTOSITE; LABRADORITE; OLIGOCLASE.

PLAGUE (in Gr. Noonos; in Lat. pestis, pestilentia), in medicine, a term given to any epidemic disease causing a great mortality, and used in this sense by Galen and the ancient medical writers, but now confined to a special disease, otherwise called Oriental, Levantine, or Bubonic Plague, which may be shortly defined as a specific infectious fever, one variety being characterized by buboes (glandular swellings) and carbuncles. This definition excludes many of the celebrated pestilences recorded in history—such as the plague of Athens, described by Thucydides; that not less celebrated one which occurred in the reign of Marcus Aurelius and spread over nearly the whole of the Roman world (A.D. 163-180), which is referred to, though not fully described, by the contemporary pen of Galen; and that of the 3rd century (about 253), the symptoms of which are known from the allusions of St Cyprian (Sermo de mortalitate). There is a certain resemblance between all these, but they were very different from Oriental plague. "Plague" was formerly divided into two chief varieties: (1) mild plague, pestis minor, larval plague (Radcliffe), peste fruste, in which the special symptoms are accompanied by little fever or general disturbance; and (2) ordinary epidemic or severe plague, pestis major, in which the general disturbance is very severe. Cases which are rapidly fatal from the general disturbance without marked local symptoms have been distinguished as fulminant plague (pestis siderans, peste foudroyante).

History up to 1880.—The first historical notice of the plague is contained in a fragment of the physician Rufus of Ephesus, who lived in the time of Trajan, preserved in the Collections of Orosius.2 Rufus speaks of the buboes called pestilential as being especially fatal, and as being found chiefly in Libya, Egypt and Syria. He refers to the testimony of a physician Dionysius, who lived probably in the 3rd century B.C. or earlier, to Dioscorides and Posidonius, who fully described these buboes in a work on the plague which prevailed in Libya in their time. Whatever the precise date of these physicians may be, this passage shows the antiquity of the plague in northern Africa, which for centuries was considered as its home. The great plague referred to by Livy (Ix. Epitome) and more fully by Orosius (Hist. iv. 11) was probably the same, though the symptoms are not recorded. It is reported to have destroyed a million of persons in Africa, but is not stated to have passed into Europe.

It is not till the 6th century of our era, in the reign of Justinian, that we find bubonic plague in Europe, as a part of the great cycle of pestilence, accompanied by extraordinary natural phenomena, which lasted fifty years, and is described with a singular misunderstanding of medical terms by Gibbon in his fourth chapter. The descriptions of the contemporary writers Procopius, Evagrius and Gregory of Tours are quite unmistakable.3 The plague of Justinian began at Pelusium in Egypt in A.D. 542; it spread over Egypt, and in the same or the next year passed to Constantinople, where it carried off 10,000 persons in one day, with all the symptoms of bubonic plague. It appeared in Gaul in 546, where it is described by Gregory of Tours with the same symptoms as lues inguinaria (from the frequent seat of buboes in the groin). In Italy there was a great mortality in 543, but the most notable epidemic was in 565, which so depopulated the country as to leave it an easy prey to the Lombards. In 571 it is again recorded in Liguria,

1 Amm. Marcell. xiii. 7; see Hecker, De peste Animantia (Berlin, 1837).
3 Evagrius, Hist. eccles. iv. 29; Procopius, De bello persico, ii. 22, 23.
and in 900 a great epidemic at Rome is connected with the pontificate of Gregory the Great. But it spread in fact over the whole Roman world, beginning in maritime towns and radiating inland. In another direction it extended from Egypt along the north coast of Africa. Whether the numerous pestilences recorded in the 7th century were the plague cannot now be said; but it is possible the pestilences in England chronicled by Bede in the years 664, 672, 679 and 683 may have been of this disease, especially as in 690 *pestis inguinaria* is again recorded in Rome. For the epidemics of the succeeding centuries we must refer to more detailed works.  

It is impossible, however, to pass over the great cycle of epidemics in the 14th century known as the Black Death.

The Black Death.

Whether in all the pestilences known by this name the disease was really the same may admit of doubt, but it is clear that in some at least it was the bubonic plague. Contemporary observers agree that the disease was introduced from the East; and one eyewitness, Gabriel de Mussis, an Italian lawyer, traced, or indeed accompanied, the march of the plague from the Crimea (whither it is said to have been transported from Tartary), where with a handful of survivors of a Genoese expedition he landed probably at the end of the year 1347. He narrates how the few that had themselves escaped the pest transmitted the contagion to all they met. Other accounts, especially old Russian chronicles, place the origin of the disease still farther east, in Cathay (or China), where, as is confirmed to some extent by Chinese records, pestilence and destructive inundations are said to have destroyed the enormous number of thirteen millions. It appears to have passed by way of Armenia into Asia Minor and thence to Egypt and northern Africa. Nearly the whole of Europe was gradually overrun by the pestilence. It reached Sicily in 1346, Constantinople, Greece and parts of Italy early in 1347, and towards the end of that year Marseilles. In 1348 it attacked Spain, northern Italy and Rome, eastern Germany, many parts of France including Paris, and England; from England it is said to have been conveyed to the Scandinavian countries. In England the western counties were first invaded early in the year, and London in November. In 1349 we hear of it in the midlands; and in subsequent years, at least till 1357, it prevailed in parts of the country, or generally, especially in the towns. In 1352 Oxford lost two-thirds of her academical population. The outbreaks of 1361 and 1368, known as the second and third plagues of the reign of Edward III., were doubtless of the same disease, though by some historians not called the black death. Scotland and Ireland, though later affected, did not escape.

The nature of this pestilence has been a matter of much controversy, and some have doubted its being truly the plague. But when the symptoms are fully described they seem to justify this conclusion, one character only being thought to make a distinction between this and Oriental plague, viz. the special implication of the lungs as shown by spitting of blood and other symptoms. Guy de Chauliac notes this feature in the earlier epidemic at Avignon, not in the later. Moreover, as this complication was a marked feature in certain epidemics of plague in India, it has been noted that a Hiper variety of plague, *pestis indica*, still found in India, is that which overruns the whole in the 14th century. But the same symptoms (haemoptysis) have been seen, though less notably, in many

2 See the original account reprinted with other documents in Häser, *op. cit.;* also Hecker, *Epidermische der MittelAlg. trans*, by Babington, Sydenham Soc. (London, 1844); Volkskrankheiten des Mittelalters, ed. Hirsch (Berlin, 1865); R. Hoening, *Der schwere Tod in Deutschland* (London, 1882).

In the 15th century the plague recurred frequently in nearly all parts of Europe. In the first quarter it was very destructive in Italy, in Spain (especially Barcelona and Seville), in Germany and in England, where London was severely visited in 1400 and 1406, and again in 1428. In 1427, 80,000 persons died in Dantzic and the neighbourhood. In 1438-1439 the plague was in Germany, and there was a new appearance at Bremen in 1439 with 9,000 towards Pope Pius II. In 1448-1450 Italy (Kircher), Germany (Lersch, from old chronicles), France and Spain, were ravaged by a plague supposed to have arisen in Asia, scarcely less destructive than it is said the black death was. England was free from plague, but the next great outbreak is recorded in 1472 and following years. In 1466, 40,000 persons died of plague in Paris; in 1477-1485 the cities of northern Italy were devastated, and in the Netherlands. In the fifteenth year of Henry VII. (1499-1500) a severe plague in London caused the king to retire to Calais.

The 16th century was not more free from plague than the 15th. Simultaneously with a terrible pestilence which is reported to have affected England, a great pestilence occurred in the Netherlands, Holland, Italy and Spain, in the first decade of the century, and revived at various times in the first half. In 1529 there was plague in Edinburgh; in London in 1537-1539, and again 1547-1548; and also in the north of England, though probably not absent before. Some of the epidemics of this period in Italy and Germany are known by the accounts of eminent physicians, as Vechs, Fracastor, Mercurialis, Borgarucci, Ingrassia, Massaria, Amici, &c., whose statements are important because the question of contagion first began to be raised, and also plague had to be distinguished from typhus fever, which began in this century to appear in Europe.

The epidemic of 1553-1554 in London and England was very severe, but a thousand thousand deaths occurred. It was a plague of an early occurrence, of which some were less afraid than of a headache (Borgarucci). In 1570, 200,000 persons died in Moscow and the neighbourhood, in 1572, 50,000 at Lyons; in 1568 and 1574 plague was at Edinburgh, and in 1570 at New-York.

When, however, the pestilence had spread over Europe, its origin was referred to Constantinople, whence it was said to have spread by sea to Malta, Sicily and Italy, and by land through the Austrian territories to Germany. Others contended that it had arisen in Greece, but that the most destructive plague known in its history. The great plague of 1522 in London seems to have been a part of the same epidemic, which was hardly extinguished by the end of the century, and is noted in London plague records from 1533. On the whole, this century shows a decrease of plague in Europe.

In the first half of the 17th century the plague was still prevalent in Europe, though considerably less so than in the middle ages. In the second half of the century the epidemic disappeared, but the third quarter the disease had disappeared or was disappearing from a great part of western Europe. The epidemics in England will be most conveniently considered in one series. From this time
onwards we have the guidance of the "Bills of Mortality" issued in London, which, though drawn up on the evidence of ignorant persons, are doubtless rather true. The accession of James I. in 1603 was marked by a very destructive plague which killed 38,000 in London, and subsequent plagues were also very destructive. The disease was not always confined to England, and it spread to the Continent and to other parts of Europe, including the Netherlands, where it was known as the "pestis annorum," or plague of the years. The disease was also known in other parts of Europe, such as France, Germany, and Italy.

It prevailed at the same time in Holland, and had done so some years previously in northern Germany. In the same year (1603) one more pest in England is said to have died of plague. The plague is said to have lasted eight years in London. At all events in 1609 we have the second great plague year, with a mortality of 11,785. After this there is a remission till about 1630, when plague again began to spread in northern Europe, especially Germany and Holland, which was at that time ravaged by war. In 1625 (the year of the siege of Breda in Holland) the third great London plague with 35,417 deaths—though the year 1624 was very excessive, and 1625 nearly so. In 1630 was the great plague of Milan, described by Ripamonti. In 1632 a severe epidemic, apparently plague, was in Derbyshire. 1636 is the fourth great plague year in London with a mortality of 10,400, and in the next year (1637) we find another great outbreak of the disease. The same year 7000 out of 20,000 inhabitants of Newcastle died of plague; in 1635 it was at Hull. About the same time, 1635-1637, plague was prevalent in Holland, and the epidemic of Nijmegen is celebrated as having been described by Diemerbroeck, whose work (Tractatus de peste, 160, 1641-1665) is one of the most important on the subject. The English epidemic was widespread and lasted till 1647, in which year, the mortality amounting to 3507, we have the fifth epidemic, which was almost entirely in the chief town. The chief typhus and malarial fevers, but plague was not unknown among them, as at Wallingford Castle (Willis, "Of Fevers," Works, ed. 1681, p. 131) and Dunster Castle. From this time till 1664 we have several small outbreaks of plague in the London area. In 1664 the great plague of London, described by Markham, is the most noteworthy. The epidemic was confined to London, and it was this which led to the plague of Great Britain, and led to the discovery of the contagious nature of the disease.

In 1664 the great plague of London began. The epidemic was confined to London, and it was this which led to the discovery of the contagious nature of the disease. The disease spread to other parts of England, and it is remarkable that it did not spread to other parts of Europe.

According to some authorities, especially Hodges, the plague was imported into London by bales of merchandise from Holland, which came originally from the Levant; according to others it was introduced by Dutch prisoners of war; but Boghurst regarded it as of local origin. It is in favour of the theory that it spread by some means from Holland that plague had been all years before but extinct in London for some seventeen years, and prevailed in Holland in 1663-1664. But from its past history and local conditions, London might well have been deemed capable of producing such an epidemic. In the bills of mortality since 1603 there are only three years when no deaths from plague are recorded. The uncleanliness of the city was comparable to that of oriental cities at the present day, and, according to contemporary testimony (Garrénières, Angliae flagellum, London, 1647, p. 85), little improved since Erasmus wrote his well-known description. The spread of the disease only partially supported the doctrine of contagion, as Boghurst says: "The disease spread more along rivers by contagion at first, nor began only at one place and spread further and further as an eating sore doth all over the body, but fell upon several places of city and suburbs like rain." In fact dissemination seems to have taken place, as usual, by the conversion of one house after another into a foci of disease, a process favoured by the fatal custom of shutting up infected houses with all their inmates, which was not only almost-equivalent to a sentence of death on all therein, but caused a dangerous concentration of the poison. The well-known custom of marking such houses with a red cross and the legend "God have mercy upon us!" was new thing: it is found in a proclamation in the possession of the present writer dated 1647; and it was probably older still. Hodges testifies to the futility and injurious effects of these regulations. The lord mayor and magistrates not only carried out the appointed administrative measures, but looked to the cleanliness of the city and the relief of the poor, so that there was little or no actual want; and the burial arrangements appear to have been well attended to. The college of physicians, by royal command, put forth such advice and prescriptions as were thought best for the emergency. But it is clear that neither these measures nor medical treatment had any effect in checking the disease. Early in November with colder weather it began to decline; and in December there was so little fear of contagion that those who had left the city "crowded back as thick as they fled." As has often been observed in other plague epidemics, sound people could enter infected houses, and even sleep in the beds of those who had died of the plague "before they were even cold or cleansed from the stench of the diseased" (Hodges). The symptoms of the disease being such as have been generally observed need not be here considered. The disease was, as褂, a feverish return of the fever which had prevailed among the poor, so as to be called the "poor's plague." Those who lived in the town in barges or ships did not take the disease; and the houses on London Bridge were but little affected. Of those doctors who remained in the city some eight or nine died, not a large proportion. Some had the rare courage to investigate the mysterious disease by dissecting the bodies of the dead. Hodges implies that he did so, though he left no full account of his observations. Dr George Thomson, a chemist and a disciple of Van Helmont, followed the example, and nearly lost his life by an attack which immediately followed.

The plague of 1665 was widely spread over England, and was

2. The period is described in Archives of the City of London 1570-1664 (London, 1878); Richardson, Plague and Pestilence in North of England (Newcastle, 1852).
4. Lactinogoria sic pestitis nupera abd populum Londinensim narratio (London, 1672), 180—In this account the disease is ascribed to the contamination of the air by the hypoplasia, or an Experimental Relation of the Last Plague in the City of London, by William Boghurst, apothecary in St Giles's-in-the-Fields (London, 1666), a MS in British Museum (Skene 349), containing important administrative measures, but locked to the cleanliness of the city and the relief of the poor, so as to be called the poor's plague. Those who lived in the town in barges or ships did not take the disease; and the houses on London Bridge were but little affected. Of those doctors who remained in the city some eight or nine died, not a large proportion. Some had the rare courage to investigate the mysterious disease by dissecting the bodies of the dead. Hodges implies that he did so, though he left no full account of his observations. Dr George Thomson, a chemist and a disciple of Van Helmont, followed the example, and nearly lost his life by an attack which immediately followed.4

The plague of 1665 was widely spread over England, and was
PLAGUE

generally regarded as having been transmitted from London, as it appeared mostly later than in the metropolis, and in many cases the importation by a particular person could be traced. Places near London were earliest affected, as Brentford, Greenwich, Deptford; but in 1665 it was evident that the disease had already spread good drainage in land, Newcastle, &c. A wider distribution occurred in the next year. Oxford entirely escaped, though the residence of the court and in constant communication with London. The exemption was attributed to precautions good drainage in land, which London was attributed to the Great Fire, but no such case existed in other cities. It has also been ascribed to quarantine, but no effective quarantine was established till 1720, so that the cessation of plague may have been due to an obvious reason, or to the precautions described above, which were taken to preserve them. In May 1743 a vessel arrived from Corfu, on board of which had occurred some suspicious deaths. The ship and cargo were burnt, but soon after cases of a suspicious form of disease were observed in the hospital and in the poorest part of the city; and in the summer a fearful epidemic of plague developed itself which destroyed 40,000 or 50,000 persons, and then became extinct without spreading to other parts of Sicily.

Spread of Plague from the East.—In the course of the epidemics of the plague in the sixteenth century the disease had spread to the East and continued to flourish in the seventeenth century, being remarkable for its short duration and spontaneous limitation (Häser).

In another direction the plague spread over Little Russia in 1770, and in 1777 it reached Northern Russia. In 1777 the city of Moscow was attacked and the disease continued till 1786.

In 1770 a destructive plague arose in Moldavia during the Russo-Turkish War, and shortly afterwards in Wallachia, apparently endemic in the former country at least. It affected also Transylvania and part of Hungary, and still more severely Poland, but was confined to Podolia, Volhynia, the Ukraine and east Germany (5° E.), not even penetrating as far as Warsaw. After destroying, it is said, 300,000 persons, and without being checked by any rigorous sanitary regulations, the disease disappeared in 1775, and then disappeared from those parts for fifteen years. In 1755-1775 plague prevailed in parts of European Turkey, whence it on one occasion extended into Transylvania, in the neighbourhood of Czernowitz, in 1777.

In 1808 plague was at Constantinople, in 1809 at Smyrna. In 1812 was a more general epidemic affecting these places and also Egypt. An outbreak at Odessa is supposed to have been brought from Constantinople, and thence to have passed to Transylvania. In 1813 a severe plague at Bucharest is supposed to have been brought from Constantinople. About the same time plague prevailed in Bosnia, and is supposed to have passed thence to Dalmatia in 1815. In 1814-1815 it again appeared in Egypt, and once more invaded the continent of Europe in Albania and Bosnia. Two insular outbreaks, Malta in 1813 and Corfu in 1815, attracted much attention as being both thought to be cases of importation by sea-traffic, and there seems good reason for this opinion.

A panic spread through Europe in 1815 in consequence of an outbreak in Noja on the eastern coast of Italy. According to one view it was imported from the opposite coast of Dalmatia, though no definite history of contagion was established; according to others, it originated endemically in that place. It remained, however, strictly confined to a small district, perhaps in consequence of the extraordinarily rigorous measures of isolation adopted by the Italian government. In 1828 an isolated epidemic occurred in Greece in the Morea, supposed to have been brought by troops from Egypt. In 1824–1825 an outbreak took place at Tutchkoff in Bessarabia; the town was strictly isolated by a military cordon and the disease did not spread. Cronstadt in Transylvania was the scene of a small outbreak in 1828, which was said to be isolated by similar measures (Lorinsen). A far more serious epidemic was connected with the campaign of the Russian army against Turkey in 1828–1829. Moldavia, Wallachia and Bessarabia were widely affected; the disease broke out also in Odessa and the Crimea, and isolated cases occurred in Transylvania. The most northerly points reached by the plague were near Czernowitz on the frontier of Bessarabia and Bukowina, and its limitation was as before attributed to the Russian and Austrian military cordons.

In 1831 another epidemic occurred in Constantinople and Roumellia; in 1837 again in Roumellia and in Odessa—its last appearance in these regions, and the last on the European continent except an isolated outbreak in Dalmatia in 1840, and one in Constantinople in 1841.

The plague-epidemics in Egypt between 1833 and 1845 are very important in the history of plague, since the disease was almost for the first time scientifically studied in its home by skilled European physicians, chiefly French. The disease was found to be less contagious than reported to be by popular tradition, and most of the French school went so far as to deny the contagiousness of the disease altogether. The epidemic of 1834–1835 was not less destructive than many of those notorious in history; but in 1844–1845 the disease disappeared.

In 1853 plague appeared in a district of western Arabia, the Asir country in North Yemen, and it is known to have occurred in the same district in 1815, as it did afterwards in 1874 and 1879. In 1874 the disease extended within four days' march of Mecca. From the scantiness of population the mortality was not great, but it became clear that this is one of the endemic seats of plague. 2

The return with less violence in 1859, when it died out. In the autumn of 1873 it returned, but came again to a spontaneous diminution. 3

After the epidemic of Bengazi in 1856–1859, plague was next heard of in the district of Maku, in the extreme north-west of Persia in November 1861. It occurred in a scattered population, and the mortality was not absolutely large. 4

In 1867 an outbreak of plague was reported in Mesopotamia (Irak), among the marshes of Hindieh bordering on the lower Euphrates. The epidemic began in December 1866 (or possibly earlier) and ceased in June 1867. But numerous cases of non-fatal mild bubonic disease (mild plague or pestis minor) occurred both before and after the epidemic, and according to Tholozan similar cases had been observed nearly every year from 1856 to 1865. 5

The next severe epidemic of plague in Irak began in December 1873. But facts collected by Tholozan show that pestis minor, or sporadic cases of true plague, had appeared in 1868 and subsequent years. The outbreak of 1873–1874 began about 60 m. from the origin of that of 1867. It caused a much greater mortality and extended over a much wider area than that of 1867, including the towns of Kerbela and Hilleh. After a short interval it reappeared at Divanieh in December 1874, and spread over a much wider area than in the previous epidemics. This epidemic was carefully studied by Surgeon-Major Colvill. He estimated the mortality at 4000. The epidemic ceased in July, but broke out again early in 1876, and in this year extended northwards to Bagdad and beyond. The whole area now affected extended 250 m. from north-west to south-east, and the total number of deaths was believed to be 20,000. In 1877 plague also occurred at Shuster in south-west Persia, probably conveyed by pilgrims returning from Irak, and caused great mortality.

After its customary cessation in the autumn the epidemic began again in October 1876, though sporadic cases occurred all the summer. The disease appeared in 1877 in other parts of Mesopotamia also with less severity than in 1876, but over a wider area, being now announced at Samara, a town 70 m. above Bagdad on the Tigris. The existence of plague in Bagdad or Mesopotamia was not again announced till the year 1884, when accounts again appeared in the newspapers, and in that July the usual official statement was made that the plague had been stamped out.

In 1879–1881 it appeared in a district of Mukri in Persian Kurdistan to the south of Lake Urumiah (far removed from the outbreak of 1863). The epidemic appears, however, to have died out in 1871, and no further accounts of plague there were received. The district had suffered in the great epidemic of plague in Persia in 1829–1835. In the winter 1876–1877 a disease which appears to have been plague appeared in two villages in the extreme north of the province of Khorassan, about 25 leagues from the south-east angle of the Caspian Sea. In March 1877 plague broke out in Resht, a town of 20,000 inhabitants, in the province of Gilian, near the Caspian Sea at its south-west angle, from which there is a certain amount of trade with Astrakhan. In 1832 a very destructive plague had carried off half the inhabitants. In 1877 the plague was very fatal. From March to September 4000 persons were calculated to have died. The outbreak continued till the spring of 1878. In 1877 there was a doubtful report of the same at an outlying town in some parts near the Perso-Afghan frontier. In 1878 plague again occurred in Kurdistan in the district of So-uj-Bulak, said by Dr Tholozan to be the same as in the district of Mukri where it occurred in 1879–1881. These scattered outbreaks of plague in Persian territory are the more remarkable because that country

4 For the authorities, see Häser, Op. cit.

had been generally noted for its freedom from plague (as compared with Asiatic Turkey and the Levant).

A few cases of plague occurred in January 1877 at Baku on the west shore of the Caspian, in Russian territory.

An outbreak of plague on European soil in 1878–1879 on the banks of the Volga caused a panic throughout Europe. In the summer of 1877 a disease prevailed in several villages in the neighbourhood of Astrakan and laid itself to itself, which was a clearly mild form of plague (pestis minor). It caused no deaths (or only one due to a complication) and died out apparently spontaneously. An official physician, Dr Kastorsky, who investigated the matter for the government, declared the disease to be identical with that prevailing in the same year at Resht in Persia; another physician, Dr Janizky, even gave it the name of pestis nostras. In October 1878 some cases appeared in the stanitsa or Cossack military settlement of Vetlanka, 130 m. from Astrakan on the right bank of the Volga, which seem to have puzzled the physicians who first observed them, but on the 30th of November were recognized as being but the same mild plague as had been observed the year before near Astrakan by Dr Döppner, chief medical officer of the Cossacks of Astrakan. His report on the epidemic is the only original one we have. At the end of November the disease became suddenly more severe, and most of those attacked died; and from the 21st of December it became still more malignant, death occurring in some cases in a few hours, and without any buboes being formed. No case of recovery was known in this period. At the end of the year the disease was in the fire weeks of January still more so. The last death was on the 24th of January. In the second half of December, when the disease had already lasted two months, two cases of plague occurred in several neighbouring villages, all of an extremely malignant type, so that in some places all who were attacked died. In most of these cases the disease began with persons who had been at Vetlanka, though this was not universally established. The inhabitants of these villages, terrified at the accounts from Vetlanka, strictly isolated the sick, and thus probably checked the spread of the disease. But it evidently suffered a spontaneous decline. By the end of January there were no cases left in the district except one village (Selitrennouye), where the last occurred on the 9th of February. The total number of cases in Vetlanka, out of a population of about 1700, was 417, of whom 362 died. In the other villages there were about 62 deaths from plague, and not more than two or three cases of recovery. In consequence of the alarm excited by this appearance of plague upon European soil, most European governments sent special commissions to the spot. The British commissioners were Surgeon-Major Colville and Dr F. Payne, who, like all the foreign commissioners, reached the spot when the epidemic was over. With respect to the origin of this epidemic, the possibility of its having originated on the spot, as in Resht and on the Euphrates in very similar situations, is not to be denied. An attempt was made to show that the contagion was brought home by Cossacks returning from the Turkish War, but on absolutely no evidence. In the opinion of Dr Payne the real beginning of the disease was in the year 1877, in the vicinity of Astrakan, and the sudden development of the malignant out of a mild form of the disease was no more than had been observed in other places. The Astrakan disease may have been imported from Resht or Baku, or may have been caused concurrently with the epidemics of these places by some cause affecting the basin of the Caspian generally.

**Plague in India.**—It used to be held as a maxim that plague never appeared east of the Indus; nevertheless it was observed during the 10th century in more than one distinct centre in India. So long ago as 1815 the disease appeared in Guzerat, Kattywar and Cutch, "after three years of severe famine." 1

It reappeared early next year, in the same locality, when it extended to Sind as far as Hyderabad, and in another direction south-east as far as Ahmadabad and Dholerar. But it disappeared from these parts in 1820 or early in 1821, and was not heard of again till July 1836, when a disease broke out into violence at the town of Pali in Marwar in Rajputana. It spread from Pali to the province of Meywar, but died out spontaneously during the hot season of 1837. The origin of these two epidemics was obscure. No importation from other countries could be traced.

In 1823 (though not officially known till later) an epidemic broke out at Kedarnath in Gurwhal, a sub-district of Kumaon on the south-west of the Himalayas, on a high situation. In 1834 and 1836 other epidemics occurred, which at last attracted the attention of government. In 1849–1850, and again in 1852, the disease raged very severely and spread southward. In 1853 Dr Francis and Dr Pearson were appointed a commission to inquire into the malady. In 1876–1877 another outbreak occurred. The symptoms of this disease, called maka nurree or mahomari by the natives, were precisely those of oriental plague. The feature of blood-spitting, to which much importance had been attached, appeared to be not a common one. A very remarkable circumstance was the death of animals (rats, and more rarely snakes) at the outbreak of an epidemic. The rats brought up blood, and the body of one examined after death by Dr Francis showed an affection of the lungs.

Oriental plague was observed in the Chinese province of Yunnan from 1871, and also at Pakhoo, a port in the Tongking district, in 1875—being said to have prevailed there at least fifteen years. In both places the symptoms were the same, of undoubted bubonic plague. At Pakhoo it recurs nearly every year.

In 1880 therefore plague existed or had existed within ten years, in the following parts of the world: (1) Benghaize, Africa; (2) Persian Kurdistan; (3) Irak, on the Tigris and Euphrates; (4) the Asiatic country, western Arabia; (5) on the lower Volga, Russia; (6) northern Persia and the shores of the Caspian; (7) Kumaon and Gurwhal, India; (8) Yunnan and Pakhoo, China.

**LITERATURE.**—See the following works, besides those already quoted: Kamintus, Regimen contra epidemicam sive pestem, 4 to, 1594 (many editions); Jacobus Solinus, Opus insignis de peste, 4 to (1672); Jacques de Beaufort, Le maladie de peste, 4 to (1781); Friedrich Doppner, Locastra (40 Venice, 1493); Nicolaus Massa, De febre pestilentia, 40 Venice, (1556, &c.); Fioravanti, Regimento della peste, 20 Venice 1556; John Woodall, The Surgeon's Mate, folio (London, 1639); Van Helmont, Tumultus pestis, 80 (Cologne, 1644, &c.); Muratori, Trattato generale della peste, 8vo (Modena, 1714; John Howard, An Account of Lazarettos in Europe, &c., 4 to (London, 1789); Patrick Russell, A Treatise of the Plague, 4 to (London, 1791); Thomas Hancock, Researches into the Laws of Pestilence, 8 vo (London, 1821); Foderio, Lezioni sulle epidemie, &c., 4 vols. 8vo (Paris, 1822–1824); Segur Dupeyron, Recherches historiques, &c., sur la peste (1837); Boulard, La Peste orientale, 80 (Paris, 1839); Griesinger, Die Infektionskrankheiten (2nd ed., 8vo, Erlangen, 1861). (J. F. P.)

**History since 1880.**—The most striking feature of the early history of plague summarized above is the gradual retrocession of plague from the west, after a series of exceedingly destructive outbreaks extending over several centuries, and its eventual disappearance from Europe. It appears to have come to a sudden end in one country after another, and to have been seen there no more. Those lying most to the west were the first to recover. 4 On Indian plague, see Francis, Trans. Epidem. Soc. Lond. iv. 407–408; John Murray, ibid., vol. iv. part 2: J. N. Radcliffe, Reports of Local Government Board (1875, 1876, 1877 and for 1879–1880); Parliamentary Papers (1879); Frederick Forbes, On Plague in the Bombay Presidency of India (Edinburgh, 1840) (Dissertation); Hirsch, Handbuch der historischen-geogr. Pathologie, i. 209 (1860), (Eng. trans. by Creighton, London, 1883); Hecker's Volkskrankheiten des Mittelalters (Berlin, 1865), p. 101; Webb, Pathologia index (2nd ed. Calculta, 1848).

J. N. Radcliffe's Report for 1879–1880, p. 45; Manson in Reports of Imperial Chinese Customs, special series No. 2, for half-year ended the 31st of March 1878, 18th issue, 24th issue, p. 31.

4 Notes on Epidemic Disease at Pakhoo (1882), ibid., 24th issue, p. 31.
to be freed from its presence, namely, England, Portugal and Spain. From all these it finally disappeared about 1650, at the close of a period of pandemic prevalence. Northern and central Europe became free about 1714, and the south of France in 1722. The last outbreak in northern Russia occurred about 1770. After this plague only appeared in the south-east of Europe, where in turn it gradually died away during the first half of the 19th century. In 1841 its long reign on this continent came to an end with an isolated outbreak in Turkey. From that time until quite recently it remained except, in the East. The province of Astrakhan, where a very small and limited outbreak occurred in 1858, is politically in Europe, but geographically it belongs rather to Asia. And even in the East plague was confined to more or less clearly localized epidemics; it showed no power of pandemic diffusion. In short, if we regard the history of this disease as a whole, it appears to have lost such power from the time of the Great Plague of London in 1665, which was part of a pandemic wave, until the present day.

There was not merely a gradual withdrawal eastwards lasting nearly two hundred years, but the outbreaks which occurred during that period, violent as some of them were, showed a constantly diminishing power of diffusion and an increasing tendency to localization. The sudden reversal of that long process is therefore a very remarkable occurrence. Emerging from the remote endemic centres to which it had retreated, plague has once more taken its place among the zymotic diseases with which Western communities have to reckon, and that which for more than a century has been little more than a name and a tradition has become the familiar object of investigation, carried on with all the ardour and all the resources of modern science. In what follows an attempt will be made to summarize the facts and indicate the conclusions to be drawn from recent experience.

Diffusion.—At the outset it is characteristic of this subtle disorder that the present pandemic diffusion cannot be traced with certainty to a definite time or place of origin. Herein it differs notably from other exotic diseases liable to similar diffusion. For instance, the last visitation of cholera could be traced clearly and definitely to a point of origin in northern India in the spring of 1852, and could be followed thence step by step in its march westward (see Cholera). Similarly, though not with equal precision, the last wave of influenza was shown to have started from central Asia in the spring of 1889, to have travelled through Europe from east to west, to have been carried thence across the sea to America and the Antipodes, until it eventually invaded every inhabited part of the globe (see Influenza). In both cases no doubt remains that the all-important means of dissemination was human intercourse. The movements of plague cannot be followed in the same way. With regard to origin, several endemic centres are now recognized in Asia and Africa, namely, (1) the district of Assyry in Arabia, on the eastern shore of the Red Sea; (2) parts of Mesopotamia and Persia; (3) the district of Garwhal and Kumaon in the North-West Provinces of India; (4) Yunnan in China; (5) East and Central Africa. The last was recently discovered by Dr Koch. It includes the district of Kisiba in German East Africa, and extends into Uganda. In applying the term “endemic centres” to these localities, no very precise meaning can be attached to the word. They are for the most part so remote, and the information about them so scanty, that our knowledge is largely guesswork. What we mean is that there is evidence to show that under various names a disease identical with plague has been more or less continuously prevalent for a number of years, but how long and how continuously is not known. Whether any of them are permanent homes of plague the evidence does not enable us to say. They seem, at any rate, to have harboured it since its disappearance from Europe, and probably further investigation would disclose a still wider prevalence. For instance, there are good reasons for believing that the island of Réunion has been subject, since 1849 or thereabouts, to outbreaks under the name of “lymphangie infec-tieuse,” an elegant euphemism characteristically French. In all the countries named plague appears to behave very much as it used to do in Europe from the time of the Black Death onwards. That is to say, there are periods of quiescence, with epidemic outbreaks which attract notice at irregular intervals.

Taking up the story at the point where the earlier historical summary leaves off, we get the following list of countries in which plague is known to have been present in each year (see Local Government Board’s Reports): 1880, Mesopotamia; 1881, Mesopotamia, Persia and China; 1882, Persia and China; 1883, China; 1884, China and India (as mohamari); 1885, Persia; 1886, 1887, 1888, India (as mohamari); 1889, Arabia, Persia and China; 1890, Arabia, Persia and China; 1891, Arabia, China and India (as mohamari); 1892, Mesopotamia, Persia, China, Russia (in central Asia); 1893, Arabia, China, Russia and India (as mohamari); 1894, Arabia, China and India (as mohamari); 1895, Arabia and China; 1896, Arabia, Asia Minor, China, Japan, Russia and India (Bombay); 1897, Arabia, China, Japan, India, Russia and East Africa; 1898, Arabia, Persia, China, Japan, Russia, East Africa, Madagascar and Vienna; 1899, Arabia, Persia, China, Japan, Mesopotamia, East Africa, West Africa, Philippine Islands, Straits Settlements, Madagascar, Mauritius, Réunion, Egypt, European Russia, Portugal, Sandwich Islands, New Caledonia, Paraguay, Argentina, Brazil: 1900, to the foregoing should be added Turkey, Australia, California, Mexico and Glasgow; in 1901, South Africa and in 1902 Russia chiefly at Odessa.

This list is probably by no means exhaustive, but it sufficiently indicates in a summary fashion the extent of that wave of diffusion which set in during the closing years of the 19th century. It did not fully gather way till 1896, when plague appeared in Bombay, but our modern knowledge of the disease dates from about 1884, when it attacked Hong Kong and first presented itself to accurate observation. From this point a more detailed account may be given. Plague was recognized at Hong Kong in May 1894, and there can be little doubt that it was imported from Canton, where a violent outbreak—said to have caused 100,000 deaths—was in progress a few months earlier, being part of an extensive wave of infection which is believed to have come originally out of the province of Yunnan, one of the recognized endemic centres, and to have invaded a large number of places in that part of China, including Pakhui and other seaports. Hong Kong was severely affected, and has never since been entirely free from plague. In two intermediate years—1895 and 1897—very few cases were recorded, but more recently the epidemic has gathered force again. The following table gives the cases and deaths in each of the six years 1894–1896:

The excessively high rate of mortality is probably due in part to under-statement of the number of cases. Concealment is practised by the Chinese, who are chiefly attacked, and it is easier to conceal sickness than death. Plague appears to have been equally persistent and destructive on the mainland in southern China during the period indicated, but no accurate details are available. In 1897 the Portuguese settlements of Lappa and Macao were invaded. In addition to the provinces of Yunnan, Kwang-si and Kwang-tung in southern China, plague is reported to have been present for several years in a district in Mongolia to the north of Peking, and distant about “twelve days’ ride.” More recently several localities in Mongolia and Manchuria have been affected. Formosa was attacked in 1896, and suffered considerably in subsequent years; in 1899 the Japanese government officially reported 2633 cases, with
PLAGUE

Chapter: 'Incidence According to Population'.

In 1974 deaths. Japan itself has had a certain amount of imported plague, but not on a large scale. Speaking generally, the disease has persisted and spread in the Far East since 1894, but precise information is lacking, except with regard to Hong Kong. W. J. Simpson in his Report on the Causes of the Plague in Hong Kong (1903) reports the endemicity of the plague in that colony to be maintained by (a) infection among rats often connected with infectious material in rat runs or in houses, the virus of which has not been destroyed, (b) retention of infection in houses which are rat-ridden, and (c) infected clothing of people who have been ill or died of plague. He considers the outbreaks are favoured by the seasonal heat and moisture of the spring and early summer, and the movement from place to place of infected rats or persons. He also believes that human beings may infect rats. In 310 cases of plague examined by Simpson 56% were bubonic, 40% septic and 4% pneumonic.

In 1896 plague appeared in the city of Bombay. It was certainly present in August, but was not recognized until the 23rd of September, and the diagnosis was not bacteriologically confirmed until the 15th of October. This fact should be remembered when failure to recognize the disease on its first appearance occurs elsewhere. The origin of the Bombay invasion is shrouded in obscurity. It is not even known when or in what part of the city it began (Condon, The Bombay Plague). Several theories have been put forward, and importation by sea from China is the theory which has met with most acceptance. The native form of plague, known as mahamari, is confined to the southern slopes of the Himalaya. It is described above, but that account may be supplemented by some earlier references unearthed by the Bombay Gazetteer (vol. iv.). Ibn Batatta notices two destructive pestilences in the 14th century, and Ferishta one in 1443, which he calls ta’un, and describes as very unusual in India. At the end of the 16th century there was a pestilence following a prolonged famine, and in the 17th century two violent epidemics are recorded under the names ta’un and tabû. In the second of these, which occurred in the Ahmedabad district of the Bombay Presidency in 1638-39, buboes are distinctly described. In the 18th century several pestilences are recorded without description. It is at least probable from these notes that even before the undoubted outbreak, which began in Cutch in 1812, India was no stranger to epidemic plague. To return to Bombay and 1896: the infection spread gradually and slowly at first, but during the first three months of 1897 not only was the town of Bombay severely affected, but district after district in the presidency was attacked, notably Poona, Karachi, Cutch Mandvi, Bhiwandi and Daman. The number of cases and deaths reported in the presidency, exclusive of the city, in each year down to the end of 1899, was as follows:

<table>

</table>

The total for the presidency, including the city, in four years was 325,632 cases with 252,549 deaths in a population of 26,660,421 (census of 1801). The population of the city is 821,764, but during the earlier plague period large numbers fled, so that the foregoing figures do not give the true plague incidence according to population. Moreover, concealment was extensively practised. The most striking fact brought out by the tables just given is the large and steady increase year by year in the presidency, in spite of all efforts to arrest the spread of infection. It has gone on since 1899, and it has not been confined to Bombay, but has extended over the whole of India. In 1897 it had already penetrated to Raiputana, the Punjab, the North West Provinces and the Central Provinces. In the following year Bengal, Madras, Haidarabad and Mysore were invaded. Not all these provinces suffered alike, but on the whole plague steadily strengthened its hold on India generally, and hardly relaxed it in any part. The most noteworthy details available are as follows, taken from the plague mortality returns published June 1908. In the Punjab from 179 deaths in 1897 the mortality reached a maximum of 334,897 in 1905, in Agra and Oudh they rose from 72 in 1897 to 385,802 in 1905, and in Madras Presidency from 1658 in 1899 to 20,125 in 1904.

The most striking figures, however, are those for Bombay and Bengal which are given below, as well as the total mortality in India.

</table>

Outside China and India plague has caused no great mortality in any of the countries in which it has appeared, with the exception perhaps of Arabia, about which very little is known. But some of the outbreaks are interesting for other reasons, and require notice. The first case is the singular occurrence of three deaths at Vienna in October 1898. The earliest victim was a man of the name of Barisch, employed in the pathological laboratory of the Vienna General Hospital, and told off to look after the animals and bacteriological apparatus devoted to the investigation of plague, cultures of which had been brought from India by the medical commissioners sent by the Royal Academy of Science in 1897. Barisch was drunk and out all night on the 8th of October; on the 14th of October he fell ill. Plague was suspected, but Dr. Muller, who attended the man and had studied the disease in India, would not admit the diagnosis on clinical grounds, nor was it bacteriologically established until the 19th of October. Barisch died on the 18th of October. On the 20th one of the nurses, and on the 21st Dr Muller, fell ill. Both died of pneumatic plague, from which also Barisch had undoubtedly suffered. A second nurse and a sister of mercy had feverish attacks, but no further case occurred. Barisch was shown to have been careless in the performance of his duties, and to have disregarded instructions; and the inference is that he conveyed the infection to his mouth, and so to the lungs, from the bacteriological specimens or inoculated animals. The melancholy incident illustrates several points of interest: (1) the correctness of the bacteriological theory of causation, and the identity of the bacillus pestis as the cause; (2) the infectious character of the pneumatic type of disease; (3) its high fatality; and (4) the difficulty of diagnosis.

The next occurrence of special interest is the appearance of plague in Portugal in 1899, after an absence of more than 200 years. Its origin is shrouded in obscurity. Oporto, the seat of the outbreak, had no connexion by sea with any place known to be infected, and all attempts to trace introduction ended in speculation or assumption. The most probable theory was that soldiers returning home from infected Portuguese possessions in the East brought it with them, but this does not explain the selection of Oporto and the escape of other places. The earliest
cases, according to retrospective inquiry, occurred in June 1899;
suspicions were aroused in July, but the diagnosis was not
established until August. The conclusion reached, after careful
investigation by Dr Jorge, the medical officer of health, that the
commencement really dated from June, is confirmed by the fact
that about that time the riverside labourers, who were first
affected, began to notice an illness among themselves sufficiently
novel to attract their attention and that of an English ship-
owner, who from their description suspected plague. Through
him the suspicion was conveyed to the Medical Times and
Gazette, in which the suggestion of plague at Oporto was made
before any public mention of it in the town itself. The outbreak
never assumed large proportions. It gained ground by degrees
until October, after which it declined, and eventually ceased in
February 1900. No recrudescence has been officially announced.
The number of cases recorded in a population of 150,000 was 310,
with 114 deaths, representing a case mortality of 36.7%. They
were widely scattered about the town and outlying suburbs;
but no further extension occurred, except some isolated cases at
Braga, a town 35 m. distant, and one at Lisbon, in the person
of the distinguished bacteriologist, Professor Camara Pestana,
who contracted the disease in making a post-mortem at Oporto,
and died in Lisbon.

The only other appearance of plague in Europe in 1899 was on
the Volga. Three places were affected, namely, Kolovobka,
and Krasnoyarsk, in the province of Astrakhan, and Samara,
higher up the river. All three outbreaks were small and limited,
and no further extension took place. A commission appointed
by the Russian government pronounced the disease to be
undoubtedly plague, and it appears to have been very fatal.
The origin was not ascertained.

The most interesting extensions of plague in 1900 were those
in Australia and Glasgow. The following towns were affected
in Australia: Sydney, in New South Wales; Adelaide, in South
Australia; Melbourne, in Victoria; Brisbane, Rockhampton,
Townsville, Cairns and Ipswich, in Queensland; Fremantle,
Perth and Coolgardie, in West Australia. In none of these,
with the exception of Sydney, did plague obtain a serious hold.
The total number of cases reported in Queensland was only 123,
with 53 deaths. In Sydney there were 303 cases, with 103
deaths, a case mortality of 34%. The infection is supposed to
have been brought from Nomuka, in New Caledonia, where it
was present at the end of 1899; and the medical authorities
believe that the first case, which occurred on the 10th of January,
was recognized. The outbreak, which hardly reached epidemic
proportions, lasted about six months. That in Glasgow was on
a still smaller scale. It began, so far as could be ascertained,
in August 1900, and during the two months it lasted there were
34 cases and 15 deaths. Once more the disease was not at first
recognized, and its origin could not be traced. In 1901 plague
invaded South Africa, and obtained a distinct footing both at
Cape Town and Port Elizabeth. The total number of cases
down to July was 766, with 362 deaths; the number of Europeans
attacked was 106, with 88 deaths; the rest being natives, Malays,
and Chinese and negroes. With regard to Great Britain, a
few ship-borne cases have been dealt with at different ports from
time to time since 1896, but except at Glasgow the disease has
nowhere obtained a footing on land.

Causation.—Plague is a specific infectious disease, caused by
the bacillus pestis, which was identified in 1894 by Kitasato,
and subsequently, but independently, by Yersin (see Parasitic
Diseases). It is found in the buboes in ordinary cases, in the
blood in the so-called “septicæmic” cases, and in the sputum
of pneumatic cases. It may also be present in the urine. Post
mortem it is found in great abundance in the spleen and liver.
Nothing is known of its natural history outside the body, but
on cultivation it is apt to undergo numerous involution forms.
Its presence in a patient is regarded as positive diagnostic proof
of plague; but failure to find or to identify it does not possess
an equal negative value, and should not be too readily accepted,
for many instances are recorded in which expert observers have
only succeeded in demonstrating its presence after repeated
attempts. It is clear, from the extreme variations in the severity
of the illness, that the resisting power of individuals varies
greatly. According to the Plague Research Committee of
Bombay, the predisposing causes are “those leading to a lower
state of vitality,” of which insufficient food is probably the most
important. There is no evidence that age, sex or race exercises
a distinct predisposing influence. The largest incidence in
Bombay was on young adults; but then they are more numerous
and more exposed to infection, because they go about more
than the younger and the older. Similarly, the comparative
immunity of Europeans in the East may be explained by their
different conditions of life. It is doubtful whether the distinc-
tion drawn between pestis minor and pestis major has a real
aetiological basis. Very mild cases occurring in the course of
an outbreak of typical plague may be explained by greater power
of resistance in individuals, but the epidemic prevalence of a
mild illness preceding the appearance of undoubted plague
suggests some difference or modification of the exciting cause.
“It is impossible,” writes Sir Richard Thorne (Local Government
Board Report, 1898-1899), “to read the medical history of this
disease in almost every part of the world without being impressed
with the frequency with which recognized plague has been pre-
ceded by ailments of such slight severity, involving some bubonic
enlargement of glands and some rise in body-temperature, as
to mask the real nature of the malady.” Considering the great
importance of arresting the spread of infection at the outset,
and the implicit reliance placed upon bacteriological criteria,
the aetiology of such antecedent ailments deserves more atten-
tion than has hitherto been paid to it. Of course plague does
not stand alone in this respect. Epidemic outbreaks of other
diseases—for instance, cholera, diphtheria and typhoid fever—
are often preceded and followed by the prevalence of mild illness
of an allied type; and the true significance of this fact is one of
the most important problems in epidemiology. In plague,
however, it is of special importance, on account of the peculiarly
insidious manner in which this disease fastens itself upon a
locality.

The path by which the bacillus enters the body varies. In
pneumonic cases it is presumed to enter by the air-passages,
and in bubonic cases by the skin. The Bombay Plague Research
Committee, whose experience is unequalled, say: “In a number
of instances points of inoculation were found on the extremities
of patients, from which plague cultures were obtained, and
in these cases buboes were found above the point of inocula-
tion. In the majority of instances, however, no local indication
could be found marking the point at which the microbe was
implanted.” From the fact that bacilli are hardly ever found in
the blood of bubonic cases it may be inferred that they are arrested
by the lymphatic glands next above the seat of inoculation, and
that the fight—which is the illness—takes place largely in the
bubo; in non-bubonic cases they are not so arrested, and the
fight takes place in the general circulatory system, or in the
lungs. As might be expected from these considerations, the
bubonic type is very little infectious, while pneumatic cases
are highly so, the patients no doubt having the surrounding
atmosphere by coughing. Whether infection can be introduced
through the digestive tract by infected food is doubtful. The
bacillus is non-resistant and easily killed by heat and germicide
substances, particularly acids. Little is known of its toxic
action; only a weak toxin has been obtained from cultures.
Of the lower animals, mice, rats, guinea-pigs, rabbits, squirrels
and monkeys are susceptible to the bacillus; horses, cattle,
sheep, goats, pigs, dogs and cats are more or less resistant, but
cats and dogs have been known to die of plague (Oporto, Dam-
can, Cutch and Poona). In the Great Plague of London they
were believed to carry the infection, and were killed in vast numbers.
The bacillus has been demonstrated in the bodies of fleas, flies,
bugs and ants.

Clinical Characters.—One of the results of recent observation
is the classification of plague cases under three heads, which
have already been mentioned several times: (1) bubonic, (2)
pneumonic, (3) septicæmic. The word “pesti-caemic” is
also used instead of "septicaemic," and though etymologically objectionable, it is otherwise better, as "septicaemic" already has a specific and quite different meaning.) It should be understood that this classification is a clinical one, and that the second and third varieties are just as much plague as the first. It is necessary to say this, because a misleading use of the word "bubonic" has given rise to the erroneous idea that true plague is necessarily bubonic, and that non-bubonic types are a different disease altogether. The word "plague"—or "pest," which is the name used in other languages—had originally a general meaning, and may have required qualifications when applied to this particular fever; but it has now become a specific label, and the prefix "bubonic" should be dropped.

The illness varies within the widest limits, and exhibits all gradations of severity, from a mere indisposition, which may pass almost unnoticed, to an extreme violence, only equalled by the most violent forms of cholera. The mild cases are always bubonic; the other varieties are invariably severe, and almost always fatal. Incubation is generally from four to six days, but it has been observed as short as thirty-six hours and as long as ten days (Bombay Research Committee). Incubation, however, is so difficult a thing to determine that it is unwise to lay down any positive limit. As a rule the onset is sudden and well marked. The symptoms may be described under the headings given above. (1) Bubonic cases usually constitute three-fourths of the whole, and the symptoms may therefore be called typical. In a well-marked case there is usually an initial rigor—in children convulsions—followed by a rise of temperature, with vomiting, headache, giddiness, intolerance to light; pain in epigastrium, back and limbs; sleeplessness, apathy or delirium. The headache is described as splitting; delirium is of the busy type, like delirium tremens. The temperature varies greatly; it is not usually high on the first day—from 101°F to 103°F—and may even be normal, but sometimes it rises rapidly to 104°F or 105°F or even 107°F; a fall of two or three degrees on the second or third day has frequently been observed. The eyes are red and injected; the tongue is somewhat swollen, and at first covered with a thin white fur, except at the tip and edges, but later it is dry, and the fur yellow or brownish. Prostration is marked. Constipation is the rule at first, but diarrhoea may be present, and is a bad sign. A characteristic symptom in severe cases is that the patient appears dazed and stupid, is thick in speech, and staggers. The condition has often been mistaken for intoxication. There is nothing, however, in all these symptoms positively distinctive of plague, unless it is already prevalent. The really pathognomonic sign is the appearance of buboes or inflamed glands, which happens early in the illness, usually on the second day; sometimes they are present from the first day, or are later than the first day, or are not present at all, or are not detected before the second day, or even later. The commonest seat is the groin, and next to that the axilla; the cervical, submaxillary and femoral glands are less frequently affected. Sometimes the buboes are multiple and on both sides, but more commonly they are unilateral. The pain is described as lancinating. If left, they usually suppurate and open outwards by sloughing of the skin, but they may subside spontaneously, or remain hard and indurated. Petechiae occur over buboes or on the abdomen, but they are not very common, except in fatal cases, when they appear shortly before death. Boils and carbuncles are rare. (2) Pneumonic plague was observed and described in many of the old epidemics, and particularly by two medical men, Dr Gilders and Dr Whyte, in the outbreak in Kathiawar in 1816; but its precise significance was first recognized by Childe in Bombay. He demonstrated the presence of the bacilli in the sputum, and showed that the inflammation in the lungs was set up by primary plague infection. The pneumonia is usually lobular, the onset marked by rigors, with difficult and hurried breathing, cough and expectoration. The prostration is great and the course of the illness rapid. The breathing becomes very hurried—forty to sixty respirations in the minute—and the face dusky. The expectoration soon becomes watery and profuse, with little whitish specks, which contain great quantities of bacilli. The temperature is high and irregular. The physical signs are those of broncho-pneumonia; oedema of the lungs soon supervenes, and death occurs in three or four days. (3) In septicemic cases the symptoms are those of the bubonic type, but more severe and without buboes. Prostration and cerebral symptoms are particularly marked; the temperature rises rapidly and very high. The patient may die comatose within twenty-four hours, but more commonly death occurs on the second or third day. Recovery is very rare.

There is no reason for doubting that the disease described above is identical with the European plagues of the 14th and subsequent centuries. It does not differ from them in its clinical features more than epidemics of other diseases are apt to vary at different times, or more than can be accounted for by difference of handling. The swellings and discolorations of the skin which play so large a part in old descriptions would probably be equally striking now but for the surgical treatment of buboes. Similarly, the comparatively small destructiveness of modern plague, even in India, may be explained by the improved sanitary conditions and energetic measures dictated by modern knowledge. The case mortality still remains exceedingly high. The lowest recorded is 34% in Sydney, and the highest 95% at Hong Kong in 1899. During the first few weeks in Bombay it was calculated by Dr Viegas to be as high as 99%. It is very much higher among Orientals than among Europeans. In the Bombay hospitals it was about 70% among the former, and between 30 and 40% among the latter, which was much the same as in Oporto, Sydney and Cape Town. It appears, therefore, that plague is less fatal to Europeans than cholera. The average duration of fatal cases is five or six days; in the House of Correction at Byculla, where the exact period could be well observed, it was five and a half days. Patients who survive the tenth or twelfth day have a good chance of recovery. Convalescence is usually prolonged. Second attacks are rare, but have been known to occur.

Diagnosis.—When plague is prevalent in a locality, the diagnosis is easy in fairly well-marked cases of the bubonic type, but less so in the other varieties. When it is not prevalent the diagnosis is never easy, and in pneumonic and septicemic cases it is impossible without bacteriological assistance. The earliest cases have hardly ever been even suspected at the time in any outbreak in a fresh locality. It may be taken at first for almost any fever, particularly typhoid, or for venereal disease or lymangitis. In plague countries the diseases with which it is most liable to be confounded are malaria, relapsing fever and typhus, or broncho-pneumonia in pneumonic cases.

Treatment.—The treatment of plague is still symptomatic. The points requiring most attention are the cerebral symptoms—headache, sleeplessness, delirium, &c.—and the state of the heart. Alcohol and cardiac stimulants may be required to prevent heart failure. Speaking generally, it is important to preserve strength and guard against collapse. Extracts of supra-renal gland have been found useful. Buboes should be treated on ordinary surgical principles. An antitoxic serum has been prepared from horses by the Institut Pasteur in France, but has not met with success. The results in India obtained by British and various foreign observers were uniformly unfavourable, and the verdict of the Research Committee (1900) was that the serum had "failed to influence favourably the mortality among those attacked." Success was somewhat noisily claimed for an improved method tried in Oporto, but the evidence is of little or no value. Of 143 cases treated, 21 died; while of 72 cases not treated, 46 died; but the former were all hospital patients, and included several convalescents and many cases of extreme mildness, whereas the non-treatment cases were treated at home or not at all, some being only discovered when death had made further concealment impossible. Later observations have, however, established that the Yersin-Roux serum is of undoubted benefit when used early in the case, in fact during the first twenty-four hours. Very large doses, so much as 150 cc. may be injected subcutaneously or preferably intravenously, and it is stated to modify the whole course of
the disease. Another serum has been prepared by Lustig and Galeotti.

Morbid Anatomy.—(1) Bubble cases. A bubo is found to consist of a chain of enlarged glands, surrounded by a mass of engorged connective tissue, coagulated blood and serum. Nearly all the lymphatic glands in the body are a little swollen, but the lymphatic vessels show little or no change. The spleen and liver are always enlarged, the former to sometimes twice or thrice its natural size. The lungs are engorged and oedematous, and often show haemorrhages. The kidneys are enlarged and congested. The serous membranes show petechiae and haemorrhages. The right side of the heart is frequently dilated, with clots in the cavities. The heart muscle is normal, or soft and friable. The substance of the brain, spinal cord and nerves—trunks is normal, but the membranes are engorged. (2) Pneumonic cases. The lymphatic glands are hardly affected. There is general engorgement and oedema of the lungs, with pneumatic patches varying in size and irregularly distributed. (3) Septicaemic cases. Nearly all the lymphatic glands in the body are involved, and have a characteristic appearance. They are enlarged to the size of an almond, rounded, firm and pink; there is some engorgement and oedema on section; the substance is rather soft; and can be scraped off with a knife. The surrounding tissue is not engorged or oedematous. The description of the other organs given under (1) applies also to (2) and (3).

Dissemination.—Given the bacillus, the questions arise, How is it disseminated? And what are the conditions that favour its propagation? That it is conveyed from person to person is an undoubted fact, proved by innumerable cases, and tacitly implied by the word "infectious," which is universally allowed. The sick are a source of danger and one means of dissemination, and, since the illness may be so slight as to pass unrecognized, is an obviously insidious one. The ambulatory plague patient goes far to explain the spread of the disease without leaving any track. But there is evidence that persons may carry the infection and give it to others without being ill at all themselves. One such case occurred at Glasgow, and another at Oporto. In the Glasgow case the wife of a launderman employed in handling plague linen contracted the disease. She was brought into connexion with it in no other way, and there can be no doubt that she took it from her husband, though he was not ill at all himself. The Oporto instance is still more conclusive. Two little girls had plague at Argoncille, a suburb some miles from Oporto, and were the only cases which occurred in that place. Their father was a riverside labourer, who lodged during the week in Oporto, but went home for Sunday. He was not ill, but several cases of plague occurred in the house in which he lodged. How the poison passes from one person to another is less clear. In pneumatic cases patients no doubt spread it around them by coughing, and others may take it up through the air-passages or the skin; but even then the range of infection is small, and such cases are comparatively rare. In the vast majority of cases the bacilli are in the systemic or the circulatory system, and aerial convection, even from a great distance, seems to be a improbable. This spread is brought about by the existence of hospitals and with "contacts," which goes to show that with reasonable care and under fair conditions the risk of infection from ordinary plague patients is very small. When persons live crowded together in close contact, and when they are careless with regard to discharges of all kinds from patients, the risk is obviously much increased. Discharges—vomited matters, sputa, urine and faeces—are possible media by which plague is spread from person to person. They also contaminate clothing, which thus becomes another means of dissemination capable of acting at a distance. This is the most probable explanation of the two cases of indirect infection related above. Failure to catch or induce plague from clothing that has been worn by plague patients proves nothing. Such clothing is not necessarily infectious; indeed, the probability is that it is not, unless contaminated by discharges. There is no evidence that merchandise and food-stuffs are means of dissemination, but a great deal of evidence against such a theory. Then we come to the lower animals. Attention has been concentrated on rats, and some observers seem disposed to lay upon them the whole blame for the propagation and spread of plague, which is held to be essentially a rat-borne disease. The susceptibility of rats has been noted from remote times and in many countries, particularly in China, but it has never attracted so much attention as during the recent prevalence of plague. From one place after another a great mortality among rats was reported, and the broad fact that they die of plague is incontestable. It is therefore easily intelligible that they may play an important part in multiplying and fixing the poison on a locality. As to how they convey it from man to man, the most probable is in favour of the flea as an intermediary. Mortality among rats is said to precede the appearance of human plague, but the evidence of this is always retrospective and of a very loose character. At Sydney a careful investigation was made; and the conclusion reached by Dr Tilsdell was that "there was no ground for even a suspicion that our epidemic was being maintained by any process of direct contagion between man and man," but that rats were the carriers. In Glasgow the experience was just the contrary. Personal connexion was traced in every case, and rats excluded; there was no mortality among them, and of 300 caught and examined none had plague (Chalmers). Similarly, at Oporto, personal connexion was traced in all the earlier cases; there was no mortality among rats, and no evidence to connect them with the outbreak (Jorge). Again, a comparison between rat-infested and rat-free districts in Bombay showed a much higher incidence of plague in the latter. A campaign against rats in Bombay, by which 50,000 or 60,000 were killed in a short time, had no effect in checking the disease. Plague-rats have rarely been found in ships sailing from infected ports; and though millions of these animals must have been carried backwards and forwards from quay to quay between Hong-Kong, Bombay and the great European ports, they have not brought the disease ashore.

By far the most important communication on the rôle of rats in the spread of plague is found in the "Report on the Plague Investigations in India" (Journal of Hygiene, vol. vi., No. 4; vol. vii. No. 3, 1907). The chief conclusions arrived at in the report as the result of experiments are the following:

1. Healthy rats contracted plague from infected rats when the only apparent means of communication between the two was the rat flea (xenops cheopis).

2. In 21 experiments out of 38, 55% of healthy rats living in flea-proof cages have contracted plague after receiving fleas collected from the bodies of diseased plague rats; consequently it is proved the rat flea can transmit plague from rat to rat.

3. Close and continuous contact of plague-infected animals with healthy ones does not infect the latter if fleas are excluded.

4. Plague can be induced in once fed on plague-infected rats are able to infect rats placed in flea-proof cages.

5. Guinea-pigs kept in plague-infected houses become infected with the rat flea and develop plague in a certain percentage.

6. A rat caught on plague-infected rats are able to infect rats placed in flea-proof cages.

7. Guinea-pigs placed in plague-infected houses do not contract plague if they are protected from fleas; those placed in cages protected by a barrier paper of at least six inches in radius, which the fleas cannot jump over, do not contract plague; the others not similarly protected, do.

8. Chronic plague may prevail in rats.

On this report it may, therefore, be taken that aerial infection, except, perhaps, in pneumatic cases, may be excluded, and that the chief source of infection is the flea. It was also shown that animals may become infected through the faeces of a flea which has been fed on plague-infected rats. This may serve to explain the manner in which plague-infected linen and clothing may convey the disease. The report also considers it proved that the bacillus pestis multiplies in the stomach of a flea and may remain a considerable time within its host.

Browning Smith says the following facts are admitted as known.

(1) Plague can be carried by fleas from an unhealthy rat.

(2) A flea can retain the plague bacilli alive for seven or eight days.

(3) Man is, in the majority of cases, infected through the skin, though the puncture may not be seen.

(4) The rat flea, when finding no rats, will attack man and it will also attack other animals.
Very little light has been thrown on the conditions which favour the prevalence of plague. We do not know why it has developed a diffusive activity of late years, nor why it has attacked some places and consistently passed by others, such as Singapore. The words “dirty” and “insanitary conditions” are much used, but such general terms explain nothing. Singapore, where plague has several times been introduced, but never taken hold, is probably quite as dirty and insanitary as Hong-Kong, and it is pertinently remarked by the Bombay Research Committee that fifth per se has but little influence, inasmuch as “there occurred in the House of Correction at Byculla, where cleanliness is brought as near to perfection as is attainable, an outbreak which exceeded in severity in that any of the filthy chauls and tenements around.” Again, in Oporto there is an area which combines every possible sanitary defect—dense overcrowding, great poverty, no light, no air, no drainage, no scavenging, water brought in buckets. Plague got into this quarter, but did not spread there; on the other hand, it appeared in other and vastly Superior parts of the town. Yet in at least one case neither the patient nor the “container” (i.e., the person who shut up in one room with a sentry at the door and another in the quarter) is known. The seasonal variations have been well marked and extremely regular in Bombay. The disease begins to be active in late autumn or the beginning of winter, and reaches its height in February or March, dying down in the summer. Baldwin Latham made an elaborate examination of the meteorological conditions, and more particularly of the vapour tension, from which he draws the conclusion that the seasonal variations are due to exhalation from the ground. His observations are original and worth attention.

A simpler explanation is that the people live more indoors, and are so more exposed to infection during the plague season. The curve shows two rises, one at the beginning of winter, and the other at the commencement of the monsoon, and at both these times the people are driven indoors. A broad survey of the epidemiological facts suggests some general conclusions. The outbreaks fall into two well-defined groups: (1) those in which the disease is destructive and persistent, (2) those in which its effects are slight and transient. In the former the poison clearlyfastens on the locality, and gradually increases its hold. The place is infected, not merely the people in it; for if they evacuate it, the disease soon ceases among them, and if they return in a short time, they are again attacked. Now the poison is contained, as we have already seen, in the discharges from patients, and in such infected localities the standing conditions and the habits of the people combine to retain the discharges on the premises. The floors, mostly of mud covered with dung, are fouled with spittle, vomit, and urine, and, being seldom or never cleaned out, foster a gradual accumulation of poison, to which infected rats and the concealment of illness contribute. These are just the conditions which prevailed in Europe in the old plague days. They do not prevail now in those “white countries” which have been invaded but have repelled the attack with comparative ease and little loss. It may be concluded, with some confidence, from experience and theory alike, that localities where they do not prevail may fail to keep plague out, but have very little to fear from it, except the disturbance of trade caused by the traditional terrors that still cling to the name.

Prevention.—The principles are the same as those which govern the prevention of other infectious diseases. “Sanitary cords” and the like are obsolete. International procedure is supposed to be regulated by the Venice convention of 1897 (see Quarantine), but that instrument contains an optional clause, which allows countries to do as they please with their own frontiers. Except Great Britain and Germany, they all retain quarantine in a more or less stringent form at seaports. It is generally used as a system of local extortition imposed upon travellers and shipping. According to the Venice convention, ships are divided into (1) healthy, (2) suspected, (3) infected. (1) Healthy are those free from plague throughout the voyage; (2) suspected, those in which plague has occurred, but no fresh case within twelve days; (3) infected, those in which plague has occurred within twelve days. Great Britain relies on medical inspection to remove sick or suspected cases, and supervision of the healthy arriving in such ships. If infected clothing is burnt and infected ships are disinfected. The procedure is the same as for cholera, but it has been equally successful. Ships passing through the Suez Canal are subject to similar inspection; sick persons are landed at Moses Wells, and suspected ones detained. The risk of importing plague from India has been materially lessened by medical inspection of outward-bound ships at the principal ports. This has been very thoroughly carried out at Bombay with good results. In 1897 pilgrimages from India to the Hedjaz were prohibited. By the Venice convention a number of articles of merchandise are classed as susceptible and liable to be refused admission, but the only ones which there is any reason to consider dangerous are used clothing and rags. A watch should be kept on rats at ports of arrival and on board ships from infected countries. When plague is present in a place, the measures to be taken are the usual ones for dealing with infectious disease, with some additions. The sick and suspected should be removed in special ambulances to the hospital, their soiled linen, &c., should be burnt, and the premises disinfected. Sulphuric acid, in 250, is efficient and cheaper. Suspected cases should be bestowed in a special isolated building until the diagnosis is fully determined. “Contacts” should be kept under observation. Rats should be exterminated as far as possible, especially by means of the Danyzys virus, which spreads a disease amongst rats which cannot be communicated to man. The greatest care should be taken in dealing with the hospital linen and discharges from patients. Hospital staffs should be kept apart. Inoculation with Haffkine’s prophylactic fluid should be offered to all persons willing to avail themselves of it. It is especially desirable for hospital and ambulance staffs to be inoculated with a vaccine prepared from sterilized cultures of plague bacillus. Inoculation is harmless, and the results obtained in India justify a favourable opinion of its protective efficacy. At Hubli, where nearly the whole population was inoculated between the 11th of May and the 27th of September

---

The system of inoculation against plague with a fluid prepared from sterilized virus of the disease was introduced in India by Professor Haffkine early in 1897. The composition of this fluid was subjected to severe tests, and performed with defective precautions. Haffkine, who pronounced its employment to be free from danger, and it was used on a large scale in various parts of India without producing injurious effects. In September 1902 the standard method of manufacturing this vaccine was adopted by a committee of the Indian Medical Association, and the vaccine was made under the technical supervision of Sir Lawrence Jenkins, Lieut.-Colonel Bomford, M.D., principal of the Medical College, Calcutta, and Major Semple, R.A.M.C., director of the Pasteur Institute, Kasauni, was appointed by the government of India to inquire into the disease. They found that the germ of tetanus was not introduced into the fluid before the bottle was opened at Malkowal, and they thought it probable that this might have occurred owing either to insufficient heating or to the process of filling the bottle from a larger flask having been imperfect. They also expressed the opinion that the vaccine was a valuable agent in restraining tetanus growth when added to plague prophylactic, and they, therefore, thought that its omission was a grave mistake. Experiments undertaken at the two independent laboratories appeared to confirm the view, and their conclusions, together with the data on which they were based, were submitted with the report of the commission for examination and further experiment to the Indian government. With reference to the findings of the Malkowal commission the Institute were asked to report: (1) On the comparative efficacy of the standard and new fluids as a
In Poona, out of 5595 un inoculated cases the incidence was 6.8%, while in 1300 inoculated cases it was only 0.33%. Klein also prepared a new prophylactic from the dried vomit of a guinea-pig, and one of the most interesting experiments is that of Strong (Archiv für Schiff- und tropische Hygiene, April, 1906), who uses for producing immunity in man a living virulent culture of the bacillus pestis. He immunized 40 persons without mishap and with no more unpleasant results than those occurring after vaccination. Inoculation protects against attack, and greatly modifies the illness when it fails to protect. How long the protection lasts has not been determined, but it appears to be several months at least.

The main authorities for the researches into plague are—among recent reports of years from India and elsewhere. See generally W. J. Simpson, A Treatise on Plague (1905). (A. Sl.; H. L. H.)

1858, the mean mortality among the inoculated was 1.3%; among the un inoculated 13.2%. At Daman the mortality was—un inoculated 1.6%, uninoculated 24.6%; at Dhawar, inoculated 1.3%, uninoculated 5.2%. In all these cases the numbers dealt with were large and the test fair.

Simpson, in The Practitioner (Dec. 1906), gives an analysis of the results of Haffkine’s serum inoculations as follows:

The Institute is in agreement with the commission as to the value of 5% carbolic acid in restraining tetanus growth when added to plague vaccine, and its experiments emphasize, and further emphasize the importance of this addition in preventing growth and toxin formation in a vaccine which might be liable to the possibility of contamination with spores of tetanus. (4) The conclusions of the Institute coincide with the results of experiments that a vaccine containing 10% of the tetanous taint was at the time of inoculation in the fluid contained in the bottle, but that it is impossible to determine at what stage in its history or in what way the bottle (53-a) became contaminated. The result of the inquiries by the commission and the Institute was that it could have had nothing to do with the occurrence. They agreed that there was strong evidence to show that “the contamination took place when the bottle was opened at Mowal, owing to the abandonment by the public authorities of the technical description prescribed by the Bombay laboratory, and to the consequent failure to sterilize the forces which were used in opening the bottle, and which during the process were dropped on the ground”; and that the presence of the agent was established by the inquiries made by the Indian government, and that for Mr Haffkine’s exonerated.

The evidence showed that it had been much too readily believed that the tetanus germs had entered the fluid before the bottle was opened, and that a grave injustice had been done to Mr Haffkine. As a matter of fact, in November 1907, the Indian government invited Mr Haffkine again to take up work in India.

PLAICE—PLAIN SONG

PLAICE (Pleuronectes platessa), a species of flat-fish, common on the coasts of northern Europe from Iceland to the Bay of Biscay. It is readily recognized by the yellow or orange-coloured spots which are placed in a row along the dorsal and anal fins, and scattered over the body. The eyes are on the right side, and the teeth in the jaws compressed and truncate. The scales are minute and smooth. Plaice, like other flat-fishes, prefers a sandy flat bottom to a rocky ground, and occur in suitable localities in great abundance; they spawn early in spring, and are in finest condition in the month of May. Individuals of seven or eight pounds weight are considered fish of large size, but specimens of double that weight have been caught.

See the monograph by F. J. Cole and J. Johnstone (Liverpool, 1901); and W. Garstang’s Reports on the Natural History of the Plateau (1905). See also Report du conseil international pour l’exploration de la mer, 1905 seq.

PLAIN (O. Fr. plain, from Lat. planum), a level surface; hence in physical geography a tract of country generally quite flat or comparatively so (see Geography). The adjective “plain” signifies “level,” and hence smooth, clear, simple, ordinary, &c.

PLAINFIELD, a city of Union county, New Jersey, U.S.A., about 24 m. by S.E. of New York City. Pop. (1905) 20,550. It is served by the Central Railroad of New Jersey and by electric lines connecting with neighbouring towns. It is situated for the most part on a plain; north-east are heights occupied by the suburb of Netherwood, and north in Somerset county, on the slope of the first Watchung Mountain, is the borough of North Plainfield (pop. 1901 U.S. census, 6177), which forms with Plainfield virtually a single residential and business community. Plainfield is one of the most attractive residential suburbs of New York. The city has an excellent public school system, a good public library, with an art gallery and museum. The Mahlenberg hospital, club houses and a driving track are features of the city. The value of the factory products increased from $2,437,434 in 1900 to $3,572,144 in 1905, or 46.6%. Plainfield was settled in 1684, but it was not until 1735 that the first frame house was erected. In 1760 a grist mill was erected, and for several years the place was called Milltown. The township of Plainfield was created out of Westfield township in 1847, and in 1867 Plainfield was chartered as a city.

PLAIN SONG, or PLAIN CHANT (Gregorian Music; Lat. cantus planus; Ital. canto gregoriano; Fr. chant plain), a style of unisonous music, easily recognizable by certain strongly marked characteristics, some very ancient fragments of which are believed to have been in use under the Jewish dispensation from a remote period, and to have been thence transferred to the ritual of the Christian Church.

Theories advanced as to the origin of this solemn form of ecclesiastical music are innumerable. The most widely spread opinion is that the older portion of it originated with the Psalms themselves, or at least sprang from the later synagogue music. Another theory traces the origin of plain song to the early Greeks; and the supporters of this view lay much stress on the fact that the scales in which its melodies are composed are named after the old Greek "modes." But, beyond the name, no connexion whatever exists between the two tonalities. Less reasonable hypotheses attribute the origin of the plain song to the Phoenicians, to the Egyptians, to the early Christian converts, and to the musicians of the middle ages.

XXI. 23
PLAINTIFF

Towards the close of the 4th century Ambrose of Milan, fearing the loss or corruption of the venerable melodies which had been preserved as parts of our tradition, only endeavoured to retrieve them to their primitive purity, and to teach the clergy to sing them with greater precision. A still more extensive work of the same nature was undertaken, two centuries later, by Pope Gregory the Great. And thus arose two schools of ecclesiastical music, still known as the "Ambrosian" and the "Gregorian chant"—the first of which is practised only in the diocese of Milan, while the latter is universally accepted as the authorized "Roman use." In order to explain the essential differences between these two schools, we must describe in detail some of the peculiar characteristics of plain song.

The melodies which form the répertoire of plain chant are not written in modern major and minor scales, but in certain tonalities bearing names analogous to those of the early Greek "modes," though constructed on very different principles. Of these "modes," fourteen exist in theory, though twelve only are in practical use. The intervals of each "mode" are derived from a fundamental sound, called its "final." The compass of each mode comprises eight sounds—that of the first, third, fifth, seventh, ninth, eleventh and thirteenth "modes" extending to the octave above the final, and that of the second, fourth, sixth, eighth, tenth, twelfth and fourteenth extending from the fourth note below the final to the fifth note above it. Consequently, the "finals" of the first series, called the "authentic modes," occupy the lowest place in each system of sounds, and those of the second series, called the "plagal modes," the middle place—the same "final" being common to one "authentic" and one "plagal mode." The following table exhibits the entire system, expressed in the alphabetical notation peculiar to modern English music—the "final" being indicated in each case by an asterisk, and the position of the semitones, from which each mode derives its distinctive character, by brackets.

**Authentic Modes.**

1. Dorian.  
2. Hypodorian.  
3. Phrygian.  
5. Lydian.  
6. Hypolydian.  
7. Mixolydian.  
8. Hypomixolydian.  
10. Lycian.  
11. Ionian.

**Plagal Modes.**

1. Dorian.  
2. Hypodorian.  
3. Phrygian.  
5. Lydian.  
6. Hypolydian.  
7. Mixolydian.  
8. Hypomixolydian.  
10. Lycian.  
11. Ionian.

Nos. 11 and 12 in this series are rejected, for technical reasons into which we have no space to enter; they are practically useless. Of these modes Ambrose used four only—the first four "authentic modes," now numbered 1, 3, 5 and 7. Gregory acknowledged, and is said by some historians of credit to have invented, the first four "plagal modes"—Nos. 2, 4, 6 and 8. This "plagal" system, except perhaps in the rite of the psalm, was not formally authorized until the reign of Charlemagne, who published an official decision upon the subject. In one or other of the twelve "modes" recognized by this decision every plain-chant melody is composed. The number of such melodies preserved to us, the genuineness of which is undoubted, is very large; and the collection is divided into several distinct classes, the most important of which are the melodies proper to the Psalm-Tones and Antiphons; the Ordinarium Missae, the Introits, Graduals and Offertories; the Prefations, Versicles and Responsories; the Hymns and Sequences; and the Lamentations, Exultet and other music used in Holy Week.

Of these classes the most interesting by far is that which includes the psalm-tones, or psalm-tunes, called by modern English historians, the "Gregorian tones." The oldest of these are tones 1, 3, 5 and 7, as sung by Ambrose. The antiquity of tones 2, 4, 6 and 8 is less firmly established, though there is no doubt that Gregory the Great sanctioned their use on strong traditional evidence. In addition to these, a peculiarly beautiful melody in mode 9, known as the Tones 

The oldest version of this melody now extant is undoubtedly to a certain extent impure, but tradition imputes to it a very high antiquity, and even our doubts as to the authenticity of the now generally accepted reading extend only to one single note. A widely accepted tradition points out this melody as the tune sung to In exitu Israel, as part of the Great Hallel (see Psalms), which is generally (but hardly rightly) identified with the hymn sung by Christ and His apostles immediately after the Last Supper.

One very powerful argument in favour of the Jewish origin of the psalm-tones lies in the peculiarity of their construction. It is impossible to ignore the perfect adaptation of these venerable melodies to the laws of Hebrew poetry, as opposed to those which governed Greek and Latin verse. The division of the tune into two distinct strains, exactly balancing each other, points assuredly to the intention of singing it to the two contrasted phrases which, inseparable from the constitution of a Hebrew verse, find no place in any later form of poetry. And it is very remarkable that this constructional peculiarity was never imitated, either in the earliest hymns or antiphons we possess or in those of the middle ages—evidently because it was found impossible to adapt it to any medieval form of verse—even to the Te Deum! This melody, in its complete form, known as the authentic version of the Hebrew psalm, was adapted by Ambrose to a melody of very different formation, and naturally so since so many of its phrases consist of a single clause only, balanced in the following verse. This peculiarity now passes for the most part unnoticed; and the Te Deum is constantly sung to a psalm-tone, very much to the detriment of both. But in the middle ages this abuse was unknown; and so it came to pass that, until the "School of the Restoration" gave birth, in England, to the single chant, avowedly built upon the lines of its Gregorian predecessor, and a somewhat later period to the double one, so constructed as to weld two verses of the psalm into one, often with utter disregard to the sense of the words, the venerable psalm-tones stood quite alone—the only melodies in existence to which the psalms could be chanted. And so intimate is the adaptation of these plain-chant melodies to the rhythm as well as to the sense of the sacred text, even after its translation into more modern languages, so strongly do they swing with the one and emphasize the other, that it is difficult to believe that the composition of the music was made independent of this.

Next in antiquity to the psalm-tones are the melodies adapted to the antiphons, the offertories, the graduals and the intritos, sung at High Mass. Those proper to the Ordinarium Missae are probably of later date. Those belonging to hymns and sequences are of all ages. Among the latest we possess—perhaps the very latest of any great importance—is that of Laudae Sion, a very fine one, in modes 7 and 8, adapted to the celebrated sequence written by Thomas Aquinas about 1261.

To the melodies adapted to the Lamentations and the Exsultet, as sung in the Church of Rome during Holy Week, it is absolutely impossible to assign any date at all. All we know is that they are of extreme antiquity; and beautiful beyond all description. The melody of Exsultet is, indeed, very frequently cited as the finest example of plain song in existence.

To assert that melodies so old as these have been handed down to us in their original purity would be absurd. But the presence of corruption rarely passes undetected by the initiated; and vigorous efforts have been made from time to time to purify the received text by reference to the oldest and most trustworthy MSS. attainable. Such an effort was begun on a very extensive scale by the "Congregation of Rites," at the instigation of Pope Pius IX., in the year 1868; and the labours of that learned body, together with those of the monks of Solesmes and elsewhere, have done much towards the restoration of plain chant to the highest state of purity possible. In England the Plain-Song and Medieval Music Society, founded in 1888, has also done valuable work by its publications.

(\textbf{W. S. R.})

**PLAINTIFF.** One who brings a "plaint" (Low Lat. planta plangere, beat the breast, lament), the name, in law, of the party who brings an action against another, who is called the
PLAIT—PLANARIANS

"defendant." In suits for divorce the party bringing the suit is styled the "petitioner," the party against whom it is brought the "respondent."

PLAIT (through O. Fr. plei, from Lat. plictum, folded, plicare, to fold), properly a fold, especially a fold of cloth, now usually in the collateral form "pleat." "Plait" is now principally applied to entwined strands of ribbon, hair, straw or fibre.

PLAN (from Lat. planus, flat), a diagram on a flat surface; hence by analogy any deliberate scheme or design. In architecture, a "plan" is a horizontal geometrical section of the walls of a building, or indications, on a horizontal plane, of the relative positions of the walls and partitions, with the various openings, such as windows and doors, recesses and projections, chimneys and chimney-breasts, columns, pilasters, &c. This term is sometimes incorrectly used in the sense of design (q.v.).

PLANARIANS, a well-defined group of animals, characterized externally by their ovoid or vermiform shape, their gliding movement and their soft, unsegmented, ciliated bodies; internally by that combination of low somatic type of structure and complex gonial organization which is characteristic of the Platyhelminthes (q.v.). Their low type of bodily structure may be exemplified by the facts that the mouth is the only means of ingress to and egress from the blind alimentary sac, and that no vascular system is differentiated. Most Planarians are aquatic and the cilia that cover the body produce by their beating a stirring of the water. Hence the class is generally known by the name Turbellaria.

Planarians form one of the basal groups of the animal kingdom. They are the simplest of multicellular creeping things. In them the gliding movement has become habitual. The lowest Planarians are still largely free-swimming animacule and we can trace within the limits of the group the development of the creeping habit and the consequences that flow from it. It has led to the differentiation of anterior and posterior extremities, to the formation of bilateral symmetry; and to the development of a mucilage protecting the body against friction. It entails the concentration of the scattered nervous system on the ventral surface and at the anterior end, and it has induced the segregation of the diffused sense-organs in the head. The Planarians occupy a position midway between the simple planula larva of Coelenterates and the segmented Annelids. They have probably sprung either from an early Coelomate stock, or represent an independent class descended from a two-layered parentage distinct from that of the Coelenterates; a view which is adopted in the present article.

Occurrence.—Most Turbellaria are aquatic. They abound on the seashore and in fresh water, amongst weeds or under cover of stones, shells and sand. Few of them are pelagic or deep-water forms, and only some half-dozen Planarians are known to be parasitic. A large number of land Planarians are known, chiefly from tropical and south temperate countries.

The majority of marine Planarians are nocturnal or cryptozoic, hiding away the period of low tide to avoid dessication of their soft sticky bodies and coming out at night or during high tide to feed. They are mostly carnivorous, and their movements are correlated largely with the nature of their food. The smaller, more active species occur in companies amongst the finer seaweeds over which they creep or swim in pursuit of their food. The larger marine species occur singly or in pairs on Ascidians, Nullipores or Polyzoa, from whence as the tide rises they issue to feed. By the time the next low tide exposes them, these Planarians have so completely digested their meal that we know very little of its nature. The common fresh-water Planarians form either little companies of a dozen or more, usually of a single species, huddled together under a stone or in some cranny (see Pearl [8]), or societies of several species that inhabit Sphagnum and other fresh-water vegetation. Thence this fresh-water planarian fauna is of two kinds, the fauna of permanent and that of temporary sheets of water and both show a certain adaptation to their environment. The latter, being subject to greater extremes of temperature than the lacustrine Planarians, produce thick-shelled eggs only. The development of these eggs is rapid in warm water, slow in cold: so that a pool after a few days of early spring sunshine is soon populated and provision is made for the continuance of the race should a cold snap follow. The lacustrine Planarians exhibit a different form of adaptation. The eggs laid by many of these animals are either thin-shelled and rapidly hatched or thick-shelled and slowly hatched. The lake-water, however, is in spring, even after sunshine, of a much lower temperature than that of pool-water, but the masses of Sphagnum and other weeds that border lakes and marshes are often warmer than the open water and may be as much as 13° or 15° C. higher in temperature. Here the Planarians assemble to benefit by the warmth, and under such favourable conditions lay thin-shelled eggs which rapidly develop; whilst in colder surroundings or at the onset of winter thick-shelled resting eggs are laid. In this manner we can understand the abundance of Planarian life in cold meres and transitory pools in Great Britain, Scandinavia, Finland, Denmark and North America.

In contrast to the general habit among Turbellaria of haunting dim or dark places, the station chosen by a few species is exposed and strongly illuminated. The marine Convoluta and Polychaeris and the fresh-water Vortex viridis may be taken as examples. Convoluta paradoxa occurs among brown weeds which receive much light during neap tides and strong direct sun or light every fortnight. Polychaeris creeps about the New England shore without resorting habitually to cover, and is also strongly insolated. Vortex resembles the green Hydra of our ponds in choosing the lightest side of its surroundings; and finally, Convoluta roscoffensis paints the beach green in Brittany, part of Normandy and Natal. In every such case the Planarian is coloured brown or green by the presence of photosynthetically active cells and the singular heliotropic habit of these Turbellaria is associated with the illumination necessary for the activity of these coloured cells.

Only one branch of the Planarians has become terrestrial, but this has spread over almost all the whole globe. One species (Rhynchodemus terrestris, fig. 1, c) is fairly common in Great Britain under stones, logs and occasionally on fungi, but the Holarctic countries (North America, Europe and North Africa, North Asia) are extremely poor in terrestrial species. In countries lying in the centre and in the south of the great continents and in the south temperate continental islands and archipelagoes these land Planarians become more abundant and varied; and being frequently transported with earth or plants they are often found in hothouses and botanical gardens far from their native country. Their distribution offers some points of special interest showing a close relationship between the South American fauna and that of Australia and New Zealand: between the land Planarians of Madagascar, of Ceylon and of Indo-Malaysia: and a marked contrast between Japan and the rest of the Palaearctic region (see Von Graf [1], 1890).

External Characters.—Planarians range from the minute forms no larger than Infusoria to ovate, marine species, 6 in. in diameter and to ribbon-like land forms 8 in. in length. The majority are small, somewhat cylindrical organisms with a flat creeping surface. Others, comprising the common fresh-water and marine forms, are flattened and leaf-like, often provided with a pair of tentacles near the front end of the body, and in some cases the whole dorsal surface is beset with papillae. The land forms are elongate and smooth, and their anterior extremity is often modified into the arcuate shape of a cheese-cutter. Their movements are usually of a gliding character. The minute forms perform short excursions into the water round their station, and in so doing recall Infusoria. The larger forms, in addition to gliding like pellicles, fold the expanded anterior part of their body into a couple of fins, by which they swim after the fashion of a skate. The folded margins of other forms clasp the weeds on which they live. Adhesion is effected by the mucous investment of the body and frequently by some specially developed local secretion of slime, or by a sucker. By these means, aided by their
algal-frequenting and cryptic habits, the Turbellaria, though soft-bodied, are able to withstand the violence of the waves.

The anterior end in all Turbellaria is the site of the chief sense-organs, and in some forms (Proboscidea) becomes transformed into an invaginable proboscis of highly tactile nature. Such forms lead naturally to the Nemertina (q.v.).

Coloration.—The coloration of Planarians is of interest. The flattened marine forms are often brilliantly coloured on the dorsal surface, either uniformly or with some striking marginal band; or they may exhibit longitudinal bands of contrasting tints or a mottled appearance. The significance of these colours is not fully understood, but in some cases of empathetic coloration the derivative function of the pigments is probably to aid cryptic resemblance. The terrestrial Planarians exhibit the most striking patterns in longitudinal striping and cross-bars which appear to have no relation to the environment of these essentially nocturnal animals. The freshwater forms are colourless or dusky, often dark-brown, possibly in relation to the retention of heat; but in a number of both fresh-water and marine Planarians a green colour is present, constantly in some species, sporadically in others.

This green effect is due to the infection of the Planarian by a minute alga which multiplies in the tissues and may profoundly affect the habits and even the structure of its "host." The planarian so affected acquires a heliotropic habit; it becomes gregarious and in extreme cases ceases to ingest solid food. In *Convoluta racovitensis* the green cells have become indispensable. They function both as the nutritive and excretory organs of the Planarian, and the young animal cannot develop until it is infected and has acquired a supply of these green cells which become incorporated into its tissues (Gamble and Keeble [7]). Brown algal cells (Zooxanthellae) are known in other species of *Convoluta*.

Food.—The food of Turbellarians consists, in the smaller species, of diatoms, unicellular algae, microscopic animals and other Turbellarians; in the larger ones, of worms, molluscs and insects. The fine feeders capture their food chiefly at night by gulping down the minute organisms that settle or swim in their neighbourhood. The coarse feeders enclose their prey with a coating of slime and then proceed either to engulf it in their expansible mouth or to perforate it by their trumpet-like pharynx. The mouth is remarkably variable in position (fig. 2). In many flattened Planarians it is placed centrally on the ventral surface somewhat as in a jelly-fish. In the majority it is nearer the anterior end, but in a few remarkably elongate forms it occupies a position near the hinder end of the animal. In the cylindrical forms (Rhabdocoela) a similar variability in the position of the mouth is met with.

Anatomy.—The structure of the Turbellaria though greatly varied in detail, conforms to a single type of somatic organization which is transitory in the higher invertebrates. The sexual organs, on the other hand, are founded on two or more types, and the astounding complications of these structures suggest that their evolution has been governed by quite other factors or combinations of factors than those that have guided the somatic evolution of the group.

All the figures of natural size, and viewed from the dorsal surface. a, e and d are marine, b and g are fresh-water, e and f are terrestrial. All found in Great Britain except d.

The posterior end in all Turbellaria is occupied by a coiled duct (the perivisceral cavity) extending from the posterior end of the alimentary canal through a caecum and several glands to the posterior end of the animal. The glandular organs consist of a row of large, glandular cells (g) which are filled with secretion (s). This secretion is released by the glandular cells into the duct (ph) and passes through the duct (d) to the posterior end of the animal where it is discharged into the mantle. The secretion contains a number of substances including enzymes which are essential for the digestion of the food. The digestive system of the Turbellaria is highly specialized and consists of a mouth, an alimentary canal (a) and a rectum. The mouth is surrounded by cilia which assist in the capture of food. The alimentary canal is divided into a pharynx, a stomach, and a rectum. The pharynx is a muscular organ which aids in the propulsion of food through the digestive tract. The stomach is the site of digestion and contains a number of digestive enzymes. The rectum is the final portion of the digestive tract and is responsible for the excretion of undigested food and waste products. The excretory system of the Turbellaria is highly developed and consists of a number of excretory organs. The excretory organs are located in the coelomic cavity and consist of a series of tubules which transport waste products from the blood to the posterior end of the animal where they are excreted. The excretory organs are connected to the coelomic cavity by a series of ducts which transport waste products to the posterior end of the animal. The excretory system is an important organ system in the Turbellaria as it plays a crucial role in the regulation of the internal environment of the animal. The Turbellaria are a phylum of flatworms that are characterized by their flattened body shape. They are found in a variety of aquatic habitats and are an important component of the food web. The Turbellaria are important as model organisms in the study of developmental biology, as they have a well-studied life cycle and are easy to culture. The Turbellaria are also important in the study of parasitology, as they are hosts to a number of parasitic helminths. The Turbellaria are a phylum of flatworms that are characterized by their flattened body shape. They are found in a variety of aquatic habitats and are an important component of the food web. The Turbellaria are also important in the study of parasitology, as they are hosts to a number of parasitic helminths.
respiratory organs are developed, probably in correlation with the absence of a blood-vascular system. On the other hand, the process of reproduction is elaborately organized. The Planarians are hermaphroditic and, as in so many other small animals, the body, after attaining maturity, becomes in many Planarians practically a genital sac and is soon exhausted by the repeated calls upon its reserves that are involved in the rapid production of eggs and spermatozoa. The intervals between successive clutches has been found in *Convoluta rосosирнa* to be a month, thus suggesting the influence of the lunar tides upon maturation.

**Integument.**—The epidermis is ciliated and highly glandular. It consists of a single layer of cubical or oblong cells with the structure seen in *fig. 3*. The glandular secretion takes various forms, such as mucus, mucinoid granular blocks, or fusiform re-fragrant homogeneous rods. These rods or "rhabditis" are

![Diagram](partly-after-luther-zoologiska-fur-universitats-zoologis-by-permission-of-wilhelm-engelmann.png)

**Fig. 4.**—Portion of a transverse section of *Mesostoma ehrenbergii*.

The epidermis (E) consists of cells divided into an outer and inner zone, the latter containing rhabditis (Rb); the cilia (C) are thickened about the middle of their length. Below the epidermis is the basement membrane (BM), a layer of circular muscles (C) and of longitudinal ones (L). Below this again is the mesenchyme (M), made up of branched cells and dorso-ventral muscle-fibres (DM). The mesenchymatous glands (Rmc) are producing rhannites (Rm) which pass outwards.

The frequently coloured red or yellow, and are highly characteristic of the Turbellaria. Their real use is unknown. In only two genera does the epidermis produce circular spines (Ac, Figs. 3 and 6) on the surface, but chitinoid hooks, spines and spirals occur frequently on the lining membrane of the male and female copulatory ducts.

Below the epidermis is a firm basement membrane into which the subjacent muscles are inserted. They are divided into outer circular and inner longitudinal groups and subdivided in the larger forms by diagonal fibres, and in the most highly differentiated Planarians there are six muscular layers, two of each kind. In a number of Turbellaria the musculature is modified to form a sucker either single or double and anterior or posterior, and it undergoes further modification in connexion with the pharynx and reproductive organs.

![Diagram](fig-6.png)

with a simple syncytial gut not sharply separated from the surrounding mesenchyma; the Laurbocoea, with a hollow gut and a perivisceral schizocoel membrane; and the Alloeocoela with a lobate gut and reduced schizocoel. The last group leads one naturally to the Tricladida; the Polyclads being an independent group.

The pharynx varies widely in structure. In the Acoela it is a mere thickening and pitting of the integument. In the Rhabdocoela a great number of elaborate modifications are found. These are based on the type of a buccal invagination, which forms the pharyngeal sheath, and from the bottom of this there springs a muscular outwardly directed tube or fold. In the Alloeocoela and Tricladida the pharynx is an elongate protrusible cylinder, and in the Polyclads it may be an immensely distensible frilled organ, the folds of which have independent movement, or an elongate tube. At the base of the pharynx lie the openings of salivary glands. In the Polycladida the section of the alimentary sac into which the pharynx opens is a median stomach from which the intestinal branches radiate. The stomach in few forms is provided with digestive glands. The branches posteriorly an independent musculature and exhibit active peristalsis. The intestines of Planarians is not ciliated, and digestion appears to be largely intracellular, and not cavitated.

**Mesenchyma.**—The mesenchyma (Bohmig: parenchyma *auctt.*) consists of a mass of branched vacuolated cells, imbedded in which lie gland-cells, pigment-cells and the excretory system. It envelops the genital organs, which though in the mesenchyma are not of it, and it forms an investment to the gut and to the space (schizocoel) which often occurs between the gut and the mass of the mesenchyma. The mesenchymatous gland-cells are of different kinds. (1) Single cells in which rods (rhamnites) are developed (*fig. 4, Rmc*). Such cells in embryonic life give rise to a process which perforates the soft basement membrane and penetrates between the epidermal cells.

The process becomes hollow, and the rhamnites pass outwards along it on to the surface of the animal, forming in many Turbellarians thickly set rows of rods on the head. (2) Similar cells contain nematocytes in a few Planarians (*Microstoma, Stenostoma, Anonymus viridis* and *Stylodiplana tarda*). Whether these
nematocysts develop in the Turbellarian is doubtful, and it is not impossible that they are derived from the tissues of some coelenterate animals eaten by the Planarian, as has been shown to be the case in the nematocysts of Eolid. (3) Cells producing aciulate spicules, sometimes associated with a spiral thread. These structures are often associated together in batteries, notably so in the remarkable genus Anonymus.

Excretory System.—The excretory system consists of protonephridia, that is, of tubes opening to the exterior by one or more apertures, and after branching extensively in the mesenchyme, end blindly in peculiar hollow cells (flame-cells) provided with a bunch of synchronously vibrating cilia. The excretory tubules have a marked sinus or groove and are provided with cilia. The motion of these cilia and of the flame-cells is to induce an outward current of the fluid from the canals, but the process of excretion seems to be performed chiefly by the branched mesenchymatous flame-cells. The position of the external opening varies greatly. It may be single or paired, mid-ventral or terminal, or again multiple and arranged in pairs along the dorsal surface (Tricladida and probably in Polycladida). The flame-cells are arranged in pairs in Tricladida, but less regularly in that mesenchyme of most forms. Finally, it is noteworthy that in the Acoela no excretory system is known.

Nervous System.—The nervous system is present in all divisions of the order. It consists of a paired, anterior ganglion lying ventral to the gut, and from this are given off, right and left, dorsal, lateral and ventral fibres interconnected by a plentiful network of nerve-cells. Acoela are acoelomate, their nervous systems are mesenchymatous, or they lack a true mesenchymatous system.

Sensory organs.—These occur in the form of tactile organs, otoliths, and eyes. The whole skin of many Planarians is sensitive, and amongst the ordinary locomotor cilia long stiff ones are found which is natural to think are tactile organs. The head-end is often provided with specialized cilia that appear to observe the sense of touch and possibly of taste also. The abundance of rhabdites, of long stiff cilia, and the great mobility and sensiveness of this region, bear out this conclusion. A further development of cephalic, sensory structures occurs in the form of a crescentic groove (Polycladida) of paired, lateral pits (Microstoma, fig. 10) of mobile papillae on the extreme front margin (Land Tricladida) and of extensible tentacles, marginal or nuchal in most Polycladida. The otocty occurs constantly in the Acoela and sporadically in every other division of the group. It is with one exception a single median organ placed over the brain, and consists of a unir or bi-cellular sac containing a caracal...

Triclad, on the other hand, fragment, without undergoing preparatory changes.

The male and female genital ducts (gono-ducts) open to the exterior, either through a common chamber on the ventral surface (most Rhabdocoelida and all Tricladida, figs. 12, 13) or by separate apertures that are also usually ventral. In the latter case, the male gonopore is usually in front of the female one (all Polycladida and some Rhabdocoelida). A separate opening is sometimes acquired by one or other of the accessory reproductive organs (as by the spermotheca in some Rhabdocoelida in which it is dorsal).

The generative organs of the Planarians are complex. Male and female germ-cells develop in one and the same individual and reach the exterior by independent ducts. These ducts are provided with accessory glands along their course and terminate in penial or vaginal structures, often of great complexity, which are surrounded by an "atrium" or invagination of the ventral body-wall. From this invagination a special vesicle "uterus" is often developed for the reception of the fertilized egg previous to oviposition.

The Acoela present the simplest arrangement. In this group (fig. 11) the male germ-cells arise in follicles each of which is the product of a single sperm-mother-cell. From these follicles, the spermatozoa enter the paired atrial ducts, each of which is provided with a simple unarmed glandular penis. The female germ-cells or ova arise from a paired ovary, some of the cells of which appear to be nurse-cells, supplying the young eggs with nourishment. When mature the eggs are transferred to the oviduct. At the point where the two oviducts join in order to open to the exterior they receive a conical sac (spermotheca) which contains spermatozoa. At this point the eggs are fertilized, and deposited in a mucilaginous mass which is attached to algae or buried in the sand. It is characteristic of the Acoela that the testes and ovaries should not be continuous with either the sperm-duct or the oviduct respectively.

In one genus of the Acoelous Turbellaria—Polycaeus—this primitive arrangement undergoes a development which foreshadows the complicated ovaria and vitellaria of higher forms. In Polycaeus the eggs mature in a special roomy chamber and are here provided with yolk which is elaborated by a sterile part of the ovary. Thus we have a differentiation of germ-cells into two portions allocated to two chambers: fertile ova which open eventu-

ally into the oviduct, and sterile ova that become yolk-cells and open into the brood-pouch.

The remaining Rhabdocoelida possess separate ovaries and yolkglands. The union between the two sets of ducts takes place in the genital atrium which is provided with a spermotheca for the fertilization of the ova, but in at least one sub-family (Cylindrostominae) the spermotheca opens by a special dorsal pore. These ova, together with the yolk and spermatozoa, are then transferred to another atrial diverticulum—the uterus, in which a shell is formed and from which they are deposited in the form of a cocoon. In addition, a muscular pouch, the so-called "bursa copulatrix," is usually present. The male organs of Rhabdocoelida are no less complex. The testes are either follicular (Allooeoeola) or compact (Rhabdocoela), and communicate indirectly or directly with the paired seminal ducts. The ducts unite at the base of an evaginable penis. This muscular organ is provided with glandular and chitinoid appendages of considerable complexity, and, in addition to these, a poison gland and duct are sometimes present. In certain genera (Macrorhynchus, Prorhynchus) the penis is used for catching prey, perhaps exclusively so in the former genus. The opening of the atrium into the oral cavity in Cylindrostominae and of the male organ into the mouth of Prorhynchus is possibly explained by this fact.

From the Allooeoeola we pass readily to the Tricladida. In both of these groups the reproductive organs are based on the same plan; but in Tricladida the separation of ovarian and vitellaria portions of the gonad is less perfectly effected. The oviduct transmits the eggs from the anteriorly placed ovary, and receives in its course the openings of numerous vitellaria (fig. 14). No distinct spermotheca is developed, but a cocoon is formed in a special chamber—
the uterus—which may either be a dilatation of the common oviduct (vagina) or of the atrium, and may open to the exterior independently (single in Ulteriporus, paired in Syncoelidium). In Bobilora the uterus is said to act as a spermtherca. In addition to these structures, accessory muscular organs are found in Dendrocoelim and developed to a high degree in land Planarians, where they form the so-called adenocheris and adenodactyl (see von Graff, 1899).

Lastly, the Polyclads offer certain distinctive sexual characters. The ovaries are follicular, very numerous, and the ova elaborate their own yolk (fig. 15). The oviducts open into a chamber which, after receiving a voluminous shell-gland, opens by a muscular bursa to the exterior. No special uterus is developed, but from the point of union of the oviduct and the shell-gland there issues a duct (Trigonoporus) which may open separately to the exterior (Trigonoporus). The testes are equally diffused and the seminal vesicles usually form a median muscular eversible sac which opens in front of the female genital pore. In certain species, however, this penial organ opens through the mouth, as in certain Rhabdocoelida. Moreover, it may be paired (Thysanozoon) or multiple. Thus in Anonymus twelve or more pairs occur. In Cryptocelidae two, four or six may be present, but in a few genera one (Trigonoporus). Polyphasia twenty pores occur ranged about the female pore, but the most posteriorly placed of these structures are devoid of a seminal duct. This condition supports the view that in Polyclads the penis was at first a glandular organ probably used for attacking prey and that it has become secondarily connected with reproduction. In confirmation of this conclusion we have the observations of Lang (5) that Yungia stabs the body of other Planclids with its penis into contact with the testes of the same organ. The name of their discoverer these girdled larvae are called Miller's larvae (fig. 15).

The Polyclads, Rhabdocoelidae the eggs are usually laid in a shell which has characteristic shapes. Each capsule contains a single ovum and several yolk cells, the arrangement facilitating the formation of dislocated megacest and microcysts. The latter give rise to the epimera which is laid down in the testes. The eggs are also laid in a semi-compact mass. However, this differs from that of other Rhabdocoelida. The ovum contains yolk-granules, and a shell, are laid in a common sac. The eggs of the former are two-layered embryo composed of a ciliated outer layer and a central syncytium. No trace of a distinct enteron or gut is visible, but the embryo grows the syncytium becomes differentiated into a more fluid central portal. A depression in the former, together with the wandering phagocytes, corresponds functionally to the separate gut of other Rhabdocoelida. Pelagic larvae with a coat of long cilia have been identified by Uljanin as belonging to the Acoela.

The development of the Tricladiida offers other peculiarities. From four to twenty or more ova are surrounded by several hundred amoeboid yolk-cells in each cocoon. Each egg-cell divides; but, as long as it remains a yolk-cell, it does not divide; and they do not all undergo division, so the remainder. The segmented ovum becomes dislocated as in some Rhabdocoels, the blastomeres moving apart from one another. The details of development are still obscure. The eggs of the Planarians are laid somewhat like those of the Acoela in a gelatinous envelope, each ovum being provided with yolk and an egg-shell which may be oculiparous. The majority of species pass through a direct development. The segmentation of the egg in Discocelids and Leptocelids has been worked out, and his results re-interpreted by Wilson and others (Hubrecht [12]). In Polyclads a distinction of germ-layers similar to that occurring in the development of Mollusca, Chaetopoda-Annelida and certain other Invertebrates, is early apparent. The ovum by unequal segmentation gives rise to megacercous and microcercous, and these are further diversified, in some forms, into tetraceras and microtetraceras (Sensu stricto). In this the progeny of protonephridial type. A simple pharynx, A median otocect (statocyst) over the brain. Small, often flattened forms. All marine and many infected by brown or green algal cells. One species parasitic in the nose. Acoels in the nose. Acoela is a group of animals parasitic in the nose. Acoela differ from other Turbellaria in being simultaneous forms.

**Systematic Arrangement.**

Order Turbellaria. —Free-living Platystyla with a ciliated epidermis. A well-developed nervous system and sense-organs concentrated at the anterior end of the body, diversified elsewhere. Fresh-water and marine forms.

Sub-order A. Rhabdocoelida. —Genus syncytial or tubular. Female gonads always compact. Acoela.

Tribe I. Acoela (fig. 11). —Mesenchyma not differentiated into separate gut and parenchyma. In excretory organs of protonephridial type. A simple pharynx, A median otocect (statocyst) over the brain. Small, often flattened forms. All marine and many infected by brown or green algal cells. One species parasitic in the nose. Acoela is a group of animals parasitic in the nose. Acoela differ from other Turbellaria in being simultaneous forms.

**Sub-order B. Polycladida.** —Large forms with flattened body, branched intestines, glandular testes and follicular ovaries or compact ovaries and yolk-glands. Acoela.

Tribe I. Trichiida. —Intestine with three main branches. A pair of compact ovaries and many yolk-glands connected by a median duct. Acoela.

**Sub-order C. Planariida.** —Protonephridial type. A simple pharynx, A median otocect (statocyst) over the brain. Small, often flattened forms. All marine and many infected by brown or green algal cells. One species parasitic in the nose. Acoela is a group of animals parasitic in the nose. Acoela differ from other Turbellaria in being simultaneous forms.

**Literature.** —(1) L. von Graff (Rhabdocoela, Acoela, Trichiida, Monographie der Polycliden, 1888), vol. I, (1899) vol. II; 1899; Die Acela, 1901; (2) Arbeiten aus der zool. Instilizait des Isser (1904); (3) Turbellaria, in Brein's Klasse v. Ordnungen d. Tierreichs, vol. II; (4) Turbellaria als Parasiten von Wirthe (Graff, 1904, 1906); (5) Lang; Die Polycliden, Fauna und Flora der Golf v. Napes, vol. VIII (1881) and (6) Whitman (1897). In the result of Expeditions conducted by Dr Willey, Stanley Gardiner and C. Crossland, Cambridge Univ. Press, and Proc. Zooi. Soc. (1902-1906); (7) Friend and Kibbee (Green Cells of Cestoda), Quart. Journ. Micr. Sci. (1891); (8) Friend and Hubrecht (affinites), Zeitschr. f. Naturwiss. (Jena, 1901); (9) Breslau (Development of Rhabdocoels), Zeitschr. f. Wiss. (1903). Besides these special works, useful general accounts of the Turbellaria will be found in Cambridge Natural History, i. 1-50; A Treatise on Zoology (Black), vol. IV, 42 and the references given by these works.

**Appendix to the Turbellaria.**

**Class Tylomorphidea.** —This small class of Platystyla possesses a special interest. It connects the Turbellaria (and in particular the Vorticella rhabdocoels) with the Trematoda. At the same time these Trematoda have a peculiar and characteristic structure which entitles the class to an independent position. The name of the class is derived from the digitate tentacles which occur on the anterior or lateral margins of the body. The body measures about 5 mm. in length, and the flattened stomach is the posterior.
part of the dorsal surface is raised up into three transverse fringed lamellae. These animals are epizoic, i.e. they live attached to the outer surface of other organisms, but are not ectoparasitic for they ingest Infusoria, Rotifiers and Diatoms. Most of the species occur on fresh-water crayfish and crabs in Chile, Madagascar, the Malay Archipelago and Australasia. Two Brazilian forms are known, one from the pulmonary chamber of the Mollusc Ampullaria and the other from water tortoises. The genus Temnocephala is found in all the countries mentioned. The two others, Craspedella and Actinodactyella are only known from Australia.

The epidermis offers an interesting transitional structure. It is still, as in Turbellaria, cellular, or rather syncytial without cell-boundaries, but in most species has lost its cilia and developed a

duced by Alfred de Vigny to François Bulos, he began to write for the "Revue des deux mondes," and continued to do so until 1850. He resumed his connexion with the journal in 1846 and contributed to it until his death in Paris on the 18th of September 1857. Gustave Planche was an altogether honest critic and refused to accept a place from Napoleon III. for fear of compromising his freedom. He was in early life a fervent admirer of George Sand, and he lavished praise on De Vigny. But he had nothing but scorn for Victor Hugo, whose earlier dramas he characterized as odes, those following Le Roi s'amuse as antitheses, and the latter ones as nothing but spectacle. His critical papers were collected under the titles: Portraits littéraires (1836-1849); Nouveaux portraits littéraires (1854); and art criticisms, Études sur l'école française (1855).

See Ernest Montégut, in the "Revue des deux mondes" (June 1858); Hatzfeld and Meunier, Les Critiques littéraires du XIXe siècle (1891).

PLANCHÉ, JAMES ROBINSON (1796-1880), English dramatist and antiquary, was born in London on the 27th of February 1796, the son of a watchmaker of Huguenot descent. In 1810 he was articled to a bookseller. In 1818 his first dramatic piece, a burlesque entitled Amoroso, King of Little Britain, was produced at Drury Lane theatre. From this time onwards he made play-writing his principal work. In 1820-1821 he wrote ten pieces for the Adelphi theatre. In 1825 he designed the dresses for Charles Kemble’s revival of King John at Covent Garden, and superintended its production. This was the first time that an historical drama had been “dressed” in the costume of the period. In 1828 he began writing regularly for Covent Garden theatre, and in 1830 was manager of the Adelphi. On Mme Vestris taking the Olympic theatre in 1831, Planche entered into an agreement with her to write a series of plays. The first of these, Olympic Reels, a burlesque, was given on the opening night of the theatre, the performance being given in correct classical costume. In 1840 his Fair One with the Golden Locks was produced by Webster at the Haymarket. In 1847 Mme Vestris became manageress of the Lyceum theatre, and Planche was engaged as her leading author and designer, his principal success being the Island of Jewels (1849). Subsequently he wrote for a number of other managements, his last dramatic piece being King Christmas (1871), but he also wrote the songs for Bula and Bijou at Covent Garden (1872).

In addition to his dramatic work Planche enjoyed a considerable reputation as an antiquary and heraldic student. He was a Fellow of the Society of Antiquaries, and aided in the foundation of the British Archaeological Association in 1843. In 1842 he published The History of British Costumes. In 1844 he was appointed Rouge Croix pursuivant of arms at the Heralds’ College, and in 1866 Somerset herald. In 1869, at the request of the War Office, he arranged the collection of armour at the Tower of London in chronological order. He died at Chelsea on the 30th of May 1880.

Planche’s Recollections and Reflections were published in 1872.

PLANCK, GOTTLIEB JAKOB (1751-1833), German Protestant divine and historian, was born at Nürtlingen in Württemberg, where his father was a notary, on the 19th of November 1751. Educated for the Protestant ministry at Blaubeuren, Bebenhausen and Tübingen, he became reiprentent at Tübingen in 1774, preacher at Stuttgart in 1780, and professor of theology at Göttingen in 1784. At Tübingen he wrote Das Tagebuch eines neuen Ekkmannes. In 1781 he published anonymously the first volume of his Geschichte des protestantischen Lehrbegriffes; the second, also anonymous, appearing in 1783, and it was completed in six volumes in 1800. It was followed by an extensive Geschichte der christlich-kirchlichen Gesellschaftsverfassung in five volumes (1803-1809). Both are works of considerable importance, and are characterized by abundant learning. He died on the 31st of August 1833. His son Heinrich Ludwig Planck (1785-1831), also professor of theology at Göttingen, published Bemerkungen über den ersten Brief an den Timotheus (1808) and Abriss d. philos. Religionslehre (1821).
PLANCK, K. C.—PLANET

PLANTCK, KARL CHRISTIAN (1870-1880), German philosopher, was born at Stuttgart on the 17th of January 1870. He studied at Tübingen, where he became doctor of philosophy in 1840 and Privatdozent in 1848. During this period the influence of Reiff led him to oppose the dominant Hegelianism of the time. In 1850-1851 he published his great book, Die Weltalter, in which he developed a complete original system of philosophy, based on the realistic view that thought should proceed from nature to the highest forms of existence in the spiritual life. Not only did Planck oppose the idealism of his confrères; his views were, in another aspect, directly antagonistic to the Darwinian theory of descent, which he specifically attacked in Wahrheit und Flachheit des Darwinismus (Nördlingen, 1872). The natural consequence of this individuality of opinion was that his books were practically disregarded, and Planck was deeply incensed. The ill success of Die Weltalter served him to new efforts, and he repeated his views in Katechismus des Rechts (1852), Grundzüge einer Wissenschaft der Natur (1864), Seele und Geist (1871), and numerous other books, which, however, met with no better fate. In the meantime he left Tübingen for Ulm, whence he came finally to the seminary of Maulbronn. He died on the 1st of June 1880 in an asylum after a short period of nervous prostration. After his death a summary of his work came into the hands of K. Köstlin (author of Aesthetics, 1869), who published it in 1881 under the title L’estament eines Deutschen, Philosophie der Natur und der Menschheit. Planck’s views were elaborately developed, but his method of exposition told heavily against their acceptance. He regarded himself as the Messiah of the German people.

Beside the works above quoted, he wrote System des reinen Idealismus (1851); Anthropologie und Psychologie auf naturwissen- schaftlicher Grundlage (1873); a political treatise, Deutschland: Suid: Deutschland und der deutsche Nationalstaat (1872); and Logisches Causalesgesetz und naturliche Zuwachsmaessigkeit (1874).

See Umfrid, Karl Planck, dessen Werke und Wirken (Tübingen, 1881); and Schmidt, "Das Lebensideal Karl Christian Planck," in the Vorträge der philosophischen Gesellschaft (Berlin, 1896).

PLANE. 1. In botany, the common name of a handsome tree known botanically as Platanus orientalis, a native of Greece and western Asia, a favourite shade-tree of the ancient Greeks and Romans, and introduced by the latter to south-west Europe. It;

is one of the most successful trees in London and other large towns; the smooth face of the leaf is easily washed by rain; and the periodical peeling of the bark also serves to get rid of impurities. It is a large tree with widely spreading branches and alternate, pinnately five-lobed leaves, resembling those of the sycamore in shape, but quite hairless and of a brighter green. The bud in the leaf axil is protected during its development by the hollow base of the leaf-stalk, which lifts off like an extin-
guisher when the leaf falls in autumn. The minute, unisexual flowers are borne in dense pendulous heads, which contain either male or female flowers; the small one-seeded fruits are densely crowded in a ball, from which they gradually separate in drying, and are readily carried by the wind. The wood, which is hard and heavy, though not strong, is used in Persia and other coun-
tries of western Asia for house construction and furniture. A variety of forms are known in cultivation, the commonest being the maple-leaved (acerioifolia), the London plane, which has usually three-lobed leaves; var. laciniata has very deeply divided leaves, and var. variegata, variegated foliage. Platanus occiden-
talis, an allied species, is a native of the United States, being most abundant and growing to its largest size in the bottom lands of the lower Ohio and the Mississippi rivers. It was introduced into England early in the 17th century, and is occasion-
ally met with in western and central Europe. Professor C. S. Sargent (Silva of North America) refers to it as the most massive if not the tallest, deciduous-leaved tree of the North American forest; it is known in America as sycamore and buttonwood. It differs from P. orientalis in its less deeply lobed, more leathery pubescent leaves and in the usually solitary balls of fruit.

2. The name of a carpenter’s hand-tool, used for levelling and smoothing (Lat. planus, level) the surface of wood. The machine tool used for a similar purpose for metals is generally known as a planing-machine or planer.

PLANET (Gr. παλαιής, a wanderer), in the ancient astrono-
my, one of seven heavenly bodies characterized by being in motion relative to the fixed stars, which last appeared immovable upon the celestial sphere. As thus defined the planets were the sun, the moon, Mercury, Venus, Mars, Jupiter and Saturn. In modern astronomy since Copernicus, the term is applied to any opaque body moving around the sun. Taken in its widest sense it applies to the satellites which are sometimes termed secondary planets. Each of these moves around a planet larger than itself, which it accompanies in its revolution round the sun. A planet not revolving round another is termed a primary planet.

The primary planets are classified as major and minor. The former are eight in number and, with the sun, form the principal members of the solar system, under which head their arrange-
ment is described. The earth on which we live is the third in the order of the major planets from the sun. With respect to the positions of their orbits relative to the earth, the other planets are distinguished as inferior and superior. The former, only two in number, comprise Mercury and Venus, which revolve between the earth and the sun. The superior planets are those whose orbits are outside that of the earth. The synodic revolution of an inferior planet is the time in which it performs a revolution relative to the line joining the earth and the sun. This is greater than its actual time of revolution. The phases or appearances presented by such a planet depend upon its configuration with respect to the earth and sun, and therefore go through their complete periods in a synodic revolution. At superior conjunc-
tion, the illuminated hemisphere of the planet is presented to the earth so that it presents the form of a full moon. As it moves towards inferior conjunction, the lines from the planet to the sun and to the earth, or the angle sun-earth as seen from the planet, on which the phase depends, continually make a greater angle. At the time of greatest elongation this angle is 90°, and the planet appears one half illuminated, like the moon at first or last quarter. Then, as it approaches inferior conjunction, the visible portion of the disk assumes the crescent form, and while the circle bounding the disk continually increases owing to the approach of the planet to the earth, the crescent becomes thinner and thinner until, near inferior conjunction, the planet is no longer visible. After conjunction the phases occur in the reverse order. The brilliancy of the planet, as measured by the total amount of light we receive from it, goes through a similar cycle of change. The point of greatest brilliancy is between inferior conjunction and greatest elongation. In the case of Venus this phase occurs about three or four weeks before and after inferior conjunction.
In the figures given above are shown the relative orbits of the planets, the orbits of Mars, the Earth, Venus and Mercury (fig. 1) being drawn to a scale twenty times that of the outer ones—Neptune, Uranus, Saturn, Jupiter (fig. 2). The positions of the planets at ten-day intervals: their actual position on the 1st of January 1910 at noon, of their nodes and nearer apses, and the points when they are farthest distant north and south of the ecliptic, are also given. The relative sizes of the planets are also given, orientated in their true axial position with regard to the ecliptic. The nearer planets (and also the Moon) are separately compared (fig. 3); and then shown (on a smaller scale) in comparison with the more distant ones (fig. 4). Finally scale diagrams of the distances of the orbits of the satellite-systems of Saturn, Uranus, Jupiter and Neptune are given (fig. 5).
The phases of a superior planet are less strongly marked, because the lines from the planet to the earth and sun increase to a right angle. The result is that although the apparent disk of Mars is sometimes gibbous in a very marked degree, it is always more than half illuminated. The case of the other superior planets, from Jupiter outward, no variation in phase is perceptible even to telescopic vision. The entire disk always seems fully illuminated.

The most favourable time for viewing an inferior planet is near that of greatest brilliancy. As it recedes further from the earth, although a continually increasing proportion of its disk is illuminated by the sun, this advantage is neutralized by the diminution in its size produced by the increasing distance. When a superior planet is in opposition to the sun it rises at sunset and is visible all night. This is also the time when nearest the earth, and therefore when the circumstances are most favourable for observation.

The greater the distance of a planet from the sun the less is the speed with which it moves in its orbit. The orbit being larger, the time of its revolution is greater in a yet larger degree. An approximation to the general laws of speed in different planets is that the linear speed is inversely proportional to the square root of the mean distance. From this follows Kepler's third law, that the squares of the times of revolution are proportional to the cubes of the mean distances.

Notes on the Plate showing Planetary Spectra.

Only those lines and bands are mentioned which are peculiar to the planets, the Fraunhofer lines are therefore omitted.

Actual observation has thus far shown no well marked deviation in the spectra of any of the inner group of planets, Mercury, Venus and Mars, from the solar spectrum as we see it. It follows that any atmospheres these planets may have must, if transparent, be rare. The evidence in the cases of Venus and Mars is given in the articles on these planets. Taking the outer group of planets, it is found that the spectrum of Jupiter shows one or more very faint shaded bands not found in that of the sun. In Saturn these bands become more marked, and in Uranus and Neptune many more are seen. The spectra in question have been observed both optically and photographically by several observers, among whom Huggins, Vogel and Lowell have been most successful. It may be said, in a general way, that seven or eight well marked dark bands, as well as some fainter ones are observable in the spectra of the two outer planets. The general conclusion from this is that these planets are surrounded by deep and dense atmospheres, semi-transparent, of a constitution which is probably very different from that of the earth's atmosphere. But it has not, up to the present time, been found practicable to determine the chemical constitution of these appendages, except that hydrogen seems to be an important constituent. (See Plate.)

Intimately associated with this subject is the question of the conditions necessary to the permanence of an atmosphere round a planet. Dr Johnstone Stoney investigated these conditions, taking as the basis of his work the kinetic theory of gases (Trans. Roy. Dublin Soc. vi. 305). On this theory every molecule of a gaseous mass is completely disconnected from every other and is in rapid motion, its velocity, which may amount to one or more thousand feet per second, depending on the temperature and on the atomic weight of the gas. At any temperature the velocities of individual molecules may now and then increase without any well-defined limit. If at the boundary of an atmosphere the velocity should exceed a certain limit fixed by the mass and force of gravity of the planet, molecules might fly away through space as independent bodies. The absence of hydrogen from the atmosphere of the earth, and of an atmosphere from the moon, may be thus explained. If the fundamental hypotheses of Dr Stoney's investigations are correct and complete, it would follow that neither the satellites and minor planets of the solar system nor Mercury can have any atmosphere. If the separate molecules thus flying away moved according to the laws which would govern an ordinary body, they would, after leaving their respective planets, move round the sun in independent orbits. The possibility is thus suggested that the matter producing the zodiacal light may be an agglomeration of gaseous molecules moving round the sun; but several questions respecting the intimate constitution of matter will have to be settled before any definite conclusions on this point can be reached. It is not to be assumed that a molecule would move through the ether without resistance as the minutest known body does, and there is probably a radical difference between the minutest particle of meteoric matter and the molecule of a gas. The relations of identity or difference between such minute matter as smoke and atmospheric haze and a true gas have yet to be fully established, and until this is done a definite and satisfactory theory of the subject does not seem possible.

Since the radiation of heat by a planet is, with our present instruments, scarcely capable of detection and measurement, the temperature of these bodies can be estimated only from general physical laws. The laws governing the radiation of heat have been so developed during recent years that it is now possible to state at least the general principle on which a conclusion as to the temperature of a planet may be reached. At the same time our knowledge of the conditions which prevail on other planets is so limited, especially as regards their atmospheres, that only more or less probable estimates of the temperature of their surfaces can even now be made. Summarily stated, some of the physical principles are these:—

1. A neutrally coloured body—understanding by that term...
Comparison spectrograms of the Moon and Mars, showing absorption bands in that of the latter, which denote the presence of water vapour in the Martian atmosphere (see Mars).

XXI. 716.
FIG. 1. ORION NEBULA.—Typical of the spectrum of the gaseous nebulae; contains bright lines of nebulum, hydrogen and helium. (The helium lines are too faint to show in this reproduction.)

FIG. 2. RIGEL.—Typical of the helium star spectrum; contains, in addition to the helium series and so-called Orion lines, dark lines of hydrogen.

FIG. 3. SIRIUS.—The hydrogen type spectrum; contains dark hydrogen lines at their greatest strength and many fine metallic lines.

FIG. 4. PROCYON.—Transition or hydrogen-to-solar type spectrum. The hydrogen lines are weaker, the metallic lines stronger, than in Sirius.

FIG. 5. SUN.—Hydrogen absorption fainter, metallic lines stronger and more numerous.

FIG. 6. ARCTURUS.—Advanced solar type spectrum.

FIG. 7. BETELGEUSE.—Typical of the spectrum partaking of the nature of that of the sun and that of the long period variable star exemplified in Fig. 8.

FIG. 8. MIRA CETI.—A spectrum typical of the long-period variable, containing bright hydrogen lines and dark bands or flutings which are sharply defined on the more refrangible edge. [Plate used in photographing this spectrum was not sensitive below λ 7200, hence no light-action below that point.]
one which absorbs the same fraction of the thermal radiation falling upon it whatever the wave length of this radiation—exposed to the sun’s radiation in void space tends to assume a definite temperature, called the normal temperature, the degree of which depends upon the distance of the body from the sun. This is a result of Kirchhoff’s laws of radiation.

2. An atmosphere surrounding such a body, if at rest, will tend to assume a state of thermal equilibrium, in which the temperature will be the same at all heights.

3. If the atmosphere is kept in constant motion by an interchange between its higher and lower portions, the tendency is towards adiabatic equilibrium, in which the temperature diminishes at a constant rate with the height, until it may approach the absolute zero. The rate of diminution depends upon the intensity of gravity and the physical constants of the gases composing the atmosphere.

4. In the actual case of a planet surrounded by an atmosphere and exposed to the sun’s radiation, the actual rate of diminution of temperature with height above the surface of the planet lies between the extreme limits just defined, the rate varying widely with the conditions. The general tendency will be towards a condition in which the temperature at the base of the atmosphere is higher than the normal, while in the upper regions it is lower. The temperature of the surface of the planet on which the atmosphere rests is determined partly by the sun’s radiation and partly by the temperature of the air. What we should generally expect in the absence of any selective absorption by the air is that the temperature of the lower air would be higher than that of the material surface on which it rests. But this condition might be reversed by the effect of such absorption in either the air or the material of the planet.

</table>

It would follow from these laws that the temperature of the superior planets diminishes rapidly with distance from the sun, and must therefore be far below that of the earth, unless they are surrounded by atmospheres of such height and density as to be practically opaque to the rays of heat, or unless they have no solid crust.

The resemblance of the spectra of Mars, Jupiter and Saturn to that of the sun leads to the conclusion that the atmospheres of these planets are transparent down to the reflecting surface of the body. The temperature of these surfaces must therefore be determined by Kirchhoff’s law, unless they resemble the sun in being entirely liquid or gaseous, or in having only solid nuclei surrounded by liquid matter in a condition of continual movement. Something of this sort has been suspected in the case of Jupiter, which has several points of resemblance to the sun. The planets Uranus and Neptune which, but for their atmospheres, would approximate to the absolute zero in temperature, may be prevented from doing so by the dense atmosphere which the spectroscope shows around them.

A very elaborate investigation of the probable mean temperatures of the surfaces of the several planets has been made by J. H. Poynting, Phil. Trans. (vol. 202A, 1904).

TABLE I. gives the elements determining the motions of each major planet, and Table II. certain numbers pertaining to its physical condition. For explanation of terms used see Orbit. The elements are given for the epoch 1900, Jan. 0, Greenwich mean time, except the mean longitudes, which are for 1910, Jan. 0.

In interpreting or using the numbers it must be remembered that only the mean distances and the daily motions can be regarded as well determined and invariable quantities. The other elements are subject to a secular variation, and all vary more or less from the action of the planets. In Table II., the reciprocal of the mass is given, the mass of the sun being unity. Some of these and other quantities are extremely uncertain. This is especially the case with the mass of Mercury, which the astronomical tables put at 1,600,000,000 of that of the sun, while G. W. Hill has computed from an estimate of the probable density of the planet that it is probably less than 1,100,000,000. In the table we assume the round number 1,000,000,000. The volumes are derived from micro-metric measures of the diameters, which are more or less uncertain. From these and the mass follows the density of each planet. From this again is derived the intensity of gravity at the surface; this is also frequently uncertain. Finally the normal temperature is that which a black or neutrally coloured body would assume when every part of it is equally exposed to the surface rays by a rapid revolution. As has already been intimated, the actual temperature may also depend upon the interior heat of the planet, which is an unknown quantity.

(S. N.)
end of the 18th century the conviction that such a planet existed was so strong that an association of astronomers was formed to search for it. The first discovered of the so-called lost planet was discovered, however, made by any member of this association, but by Giuseppe Piazzi of Palermo. On the 1st of January 1801 he noted a small star in Taurus, which, two days later, had changed its place, thus showing it to be a planet. Shortly after Piazzi's discovery the body was lost in the rays of the sun, and was not again seen until near the following opposition in 1802-1803. The orbit was then computed by C. F. Gauss, who found its mean distance from the sun to correspond with Bode's law, thus giving rise to the impression that the gap in the system was filled up. The planet received the name Ceres. On the 28th of March 1802 H. W. M. Olbers (1758-1840) discovered a second planet, which was found to move in an orbit a little larger than that of Ceres, but with a very large eccentricity and inclination. This received the name of Pallas. The existence of two planets where only one was expected led Olbers to his celebrated hypothesis that these bodies were fragments of a larger planet which had been shattered by an internal convulsion; and he proposed that search should be made near the common node of the two orbits to see whether other fragments could be found. Within the next few years two other planets of the group were discovered, making four. No others were found for more than a generation; then on the 8th of December 1843 a fifth, Astræa, was discovered by K. L. Hencke of Driesen. The same observer added a sixth in 1847. Two more were found by J. R. Hind of London during the same year, and from that time discovery has gone on at an increasing rate, until the number now known is more than six hundred and is growing at the rate of thirty or more annually.

Up to 1890 discoveries of these bodies were made by skilful search with the telescope and the eye. Among the most successful discoverers were Johann Palisa of Vienna, C. H. F. Peters (1813-1890) of Clinton, New York, and James Craig Watson (1838-1880) of Ann Arbor, Michigan. In recent times the discoveries are made almost entirely by photography. When a picture of the stars is taken with a telescope moved by clockwork, so as to follow the stellar sphere in its apparent diurnal rotation, the stars appear on the plates as minute dots. But if the image of a planet is imprinted on the plate it will generally appear as a short line, owing to its motion relative to the stars. Any such body can therefore be detected on the plate by careful examination much more expeditiously than by the old method of visual search. The number now known is so great that it is a question whether they can be much longer individually followed up so as to keep the run of their movements.

Among the distinctive features of the planets of this group one is their small size. None exist which approaches either Mercury or the moon in dimensions. The two largest, Ceres and Juno, present at opposition a visible disk about 1" in diameter, corresponding to about 400 miles. The successively discovered ones naturally have, in the general average, been smaller and smaller. Appearing only as points of light, even in the most powerful telescopes, nothing like a measure of their size is possible. It can only be inferred from their apparent magnitude that the diameters of those now known may range from fifteen or twenty miles upwards to three or four hundred, the great majority being near the lower limit. There is yet no sign of a limit to their number or minuteness. From the increasing rate at which new ones approaching the limit of visibility are being discovered, it seems probable that below this limit the number of unknown ones is simply countless; and it may well be that, could samples of the entire group be observed, they would include bodies as small as those which form the meteorites which so frequently strike our atmosphere. Such being the case, the question may arise whether the total mass of the group may be so great that its action on the major planets affects its detection. The computations of the probable mass of those known, based upon their probable diameter as concluded from the light which they reflect, have led to the result that their combined action must be very minute. But it may well be a question whether the total mass of the countless unknown planets may not exceed that of the known. The best answer that can be made to this question is that, unless the smaller members of the group are almost perfectly black, a number great enough to produce any observable effect by their attraction would be visible as a faintly illuminated band in the sky. Such a band is occasionally visible to very keen eyes; but the observations on it are, up to the present time, so few and uncertain that nothing can positively be said on the subject.

On the other hand, the faint "Gegenschein" opposite the sun is sometimes regarded as an intensification of this supposed band of light, due to the increased reflection of the sun's light when thrown back perpendicularly (see ZODIACAL LIGHT). But this supposition, though it may be well founded, does not seem to fit with all the facts. All that can be said is that, while it is possible that the light reflected from the entire group may reach the extreme limit of visibility, it seems scarcely possible that the mass can be such as to produce any measurable effect by its attraction.

Another feature of the group is the generally large inclinations and eccentricities of the orbits. Comparative few of these are either nearly circular or near any common plane. Considering the relations statistically, the best conception of the distribution of the planes of the orbits may be gained by considering the position of the plane of the celestial sphere. The December node of an orbit is defined as the point in which an axis perpendicular to the plane intersects the celestial sphere. When the poles are marked as points on this sphere it is found that they tend to group themselves around a certain position, not far from the pole of the invariable plane of the planetary system, which again is very near that of the orbit of Jupiter. This statistical result of observation is also inferred from theory, which shows that the pole of each orbit revolves around a point nearly the pole of the invariable plane with an angular motion varying with the mean distance of the body. This would result in a tendency toward an equal scattering of the poles around that of Jupiter, the latter being the centre of position of the whole group. From this it would follow that, if we referred the planes of the orbit to that of Jupiter, the nodes upon the orbit of that planet should also be uniformly scattered. Examination, however, shows a seeming tendency of the nodes to crowd into two nearly opposite regions, in longitudes of about 180° and 330°. But it is difficult to regard this as anything but the result of accident, because as the nodes move along at unequal rates they must eventually scatter, and must have been scattered in past ages. In other words it does not seem that any other than a uniform distribution can be a permanent feature of the system.

A similar law holds true of the eccentricities and the perihelia. They may both be defined by the position of the centre of the orbit relative to the sun. If e be the mean distance and ε the eccentricity of an orbit, the geometry of the ellipse shows that the centre of the orbit is situated at the distance ae from the sun, in the direction of the aphelion of the body. When the centres of the orbits are laid down in a diagram it is found that they are not scattered equally around the sun but around a point lying in the direction of the centre of the orbit of Jupiter. The statistical law follows from this fact. The position of the sun, S, and that of the centre of the orbit of Jupiter, J, are shown in fig. 1. Here S represents the position of the sun, and J that of the centre of the orbit of Jupiter. The direction JS is the perihelion of the orbit of Jupiter, which is now near longitude 12°. As the perihelion moves by its secular variation, the line SJ revolves around S. Theory then shows that for every asteroid there will be a certain point A near the line SJ and moving with the actual position of the centre of the orbit. Theory shows that C is in motion around A as a centre in the direction shown by the arrow, the linear eccentricity ae being represented by the line SC. It follows that e will be at a minimum when AC passes through S, and at a maximum when in the opposite direction. The position of A is different in the case of different planetoids, but is generally about two-thirds of the way from S to J. The lines AC for different bodies are at any time scatteredmiscellaneously around the region A as a centre. AC may be called the constant of eccentricity of the planetoid, while SC represents its actual but varying eccentricity.
Grouping of the Planetoids.—A curious feature of these bodies is that when they are classified according to their distances from the sun a tendency is seen to cluster into groups. Since the mean distance and mean motion of each planet are connected by Kepler’s third law, it follows that this grouping may also be described as a tendency toward certain times of revolution or certain values of the mean motion around the sun. This feature was first noticed by D. Kirkwood in 1870, but at that time the number of planetoids known was not sufficient to bring out its true nature. The seeming fact pointed out by Kirkwood was that, when these bodies are arranged in the order of their mean motions, there are found to be gaps in the series at those points where the mean motion is commensurable with that of Jupiter; that is to say, there seem to be no mean daily motions near the values 598°, 748° and 898°, which are respectively 2, 1/2 and 3 times that of Jupiter. Such mean motions are nearly commensurable with that of Jupiter, and it is shown in celestial mechanics that when they exist the perturbations of the planet by Jupiter will be very large. It was therefore supposed that if the commensurability should be exact the orbit of the planet would be unstable. But it is now known that such is not the case, and that the only effect of even an exact commensurability would be a libration of long period in the mean motion of the planetoid. The gaps cannot therefore be accounted for on what seemed to be the plausible supposition that the bodies required to fill these gaps originally existed but were thrown out of their orbits by the action of Jupiter. The fact can now be more precisely stated by saying that we have not so much a broken series as a tendency to an accumulation of orbits between the points of commensurability. The law in question can be most readily shown in a graphical form. In fig. 2 the horizontal line represents distances from the sun, increasing toward the left, of which certain equidistant numerical values are given below the line. Points on the line corresponding to each 0.01 of the distances are then taken, and at each point a perpendicular line of dots is drawn, of which the number is equal to that of the planetoids having this mean distance, no account being taken of fractions less than 0.01. The accumulations between the points of close commensurability with the mean motion of Jupiter may be seen by inspection. For example, at the point 2.59 the mean motion is three times that of Jupiter; at the point 2.81 twice the mean motion is equal to five times that of Jupiter; at 2.4 the mean motion is twice that of Jupiter. It will be seen that there is a strong tendency toward grouping near the values 2.75, and a lesser tendency toward 3.1 and 2.4. It is probable that the grouping had its origin in the original formation of these bodies and may be plausibly attributed to the formation of three or more separate rings which were broken up to form the group.

Continuing the question beyond these large collections, it will be seen that between the values 3.22 and 3.33 there are no orbits at all. Then between 3.3 and 3.5 there are nine orbits. The space between 3.5 and 3.9 is thus far a complete blank; then there are three orbits between 3.9 and 3.95, not shown in the diagram.

A group of great interest, of which only three members are yet known, was discovered during the years 1906-1907. The mean distance of each member of this group, and therefore its time of revolution, is so near that of Jupiter that the relations of the respective orbits are yet unknown. The case thus offered for study is quite unique in the solar system, but its exact nature cannot be determined until several more years of observation are available.

Several planetoids of much interest are situated without the limits of the groups shown in the figure. Eros is so near the sun, and its orbit is so eccentric, that at perihelion it is only about 0.16 outside the orbit of the earth. On those rare occasions when the earth is passing the perihelion point of the orbit at nearly the same time with Eros itself, the parallax of the latter will be nearly six times that of the sun. Measurements of parallax made at these times will therefore afford a more precise value of the solar parallax than can be obtained by any other purely geometrical measurement. An approach almost as close as the nearest geometrically possible one occurred during the winter of 1893-1894. Unfortunately the existence of the planet was then unknown, but after the actual discovery it was found that during this opposition its image imprinted itself a number of times upon the photographs of the heavens made by the Harvard Observatory. The positions thus discovered have been extremely useful in determining the elements of the orbit. The next near approach occurred in the winter of 1900-1901, when the planet approached within 0.32 of the earth. A combined effort was made by a number of observatories at this time to determine the parallax, both by micrometric measures and by photography. Owing to the great number of stars with which the planet had to be compared, and the labour of determining their positions and reducing the observations, only some fragmentary results of this work are now available. These are mentioned in the article Parallax. So far as can yet be seen, no other approach so near as this will take place until January 1931.

A few of the minor planets are of such special interest that some pains will doubtless be taken to determine their orbits and continue observations upon them at every available opposition. To this class belong those of which the orbits are so eccentric that they either pass near that of Jupiter or approach near that of the earth. With most of the others little more can be done than to compute their elements with a view of subsequently identifying the object when desired. Unless followed up at several oppositions after discovery, the planet is liable to be quite lost. Of those discovered before 1890 about fifteen have not again been found, so that if discovered, as they doubtless will be, identification will be difficult.

The system of nomenclature of these bodies is not free from difficulty. When discoveries began to go on at a rapid rate, the system was introduced of assigning to each a number, in the order of its discovery, and using as its symbol its number enclosed in a circle. Thus Ceres was designated by the symbol C; Pallas by P, &c., in regular order. This system has been continued to the present time. When photography was applied to the search it was frequently doubtful whether the planet of which the image was detected on the plates was or was not previously known. This led to the use of capital letters in alphabetical order as a temporary designation. When the alphabet was exhausted a second letter was added. Thus there are planetoids temporarily designated as A, B, &c., and AB, AC, &c. The practice of applying a name to be selected by the discoverer has also been continued to the present time. Originally the names were selected from those of the gods or goddesses of classical mythology, but these have been so far exhausted that the name is now left to the discretion of the person selecting it. At present it is customary to use both the number and the name, the former being necessary to the ready finding of the planetoid in a list, while the name serves for more certain identification.

PLANK, a flat piece of timber, sawn and planed; it is technically distinguished from a "board" by its greater thickness, and should measure from 2 to 4 in. in thickness and from 10 to 11 in.
PLANKTON

in width. The word comes through the Fr. planche (from post-Augustan L. planca, a nasalized adaptation probably of Gr. πλαγιά, something flat, especially a flat stone. The use of the word "plank" in the sense of an article in a political programme is of American origin and is due to the use of "platform" for the programme itself.

PLANKTON, a name invented by Professor Victor Hensen for the drifting population of the sea. This is a convenient heading under which to discuss not only plankton proper, but the benthos, or crawling population of the sea-bottom. Scientific investigation of these subjects dates from the reports of the "Challenger" expedition, which, despite its many successors, still stands out as the most important of the oceanographic expeditions, alike by the work achieved, the distance traversed, the time occupied, and the money devoted to the publication of the results. It laid the foundation of our knowledge of the physics and chemistry of ocean water, of oceanic and atmospheric currents, of the contour of the sea-bottom, and of the main features of distribution of deep-sea life. Later work has confirmed and expanded, but not revoked, the conclusions thus attained. But, in spite of this, and of several subsequent expeditions, it cannot be pretended that we are in a position to formulate general canons of marine distribution other than of the most tentative character. Two fallacies underlie many attempts to define distributional oceanic areas for special groups: the one, that such areas can be made to bear some relation to existing geographical or even national divisions; the other, that what is true for one group of the animal kingdom must hold good equally for another. It is necessary at the outset to divest oneself of these errors; oceanic conditions depend only very indirectly upon the distribution of the land, and strongly swimming or freely floating animals are not to be confined by the same factors as determine the distribution of sessile forms, whose range is governed by a variety of circumstances.

As Wyville Thomson pointed out long ago, there is but one ocean. This surrounds the southern half of the globe, and has two large gyres, generally called the Atlantic and Pacific Oceans, which meet through narrow channels in the small Arctic Ocean, and a half gyre, the Indian Ocean. The Atlantic and Pacific exhibit a striking homology of atmospheric pressure and of prevalent wind and current; the Indian, to a great extent, resembles the southern half of a larger one, but this resemblance is modified by the neighbourhood of vast land masses. The prevalent winds, dependent on the fairly constant distribution of atmospheric pressure over the great oceans, are the most important determinant of currents. As at most points in the ocean the temperature, salinity and chemical composition of the water are mainly determined by the currents—that is, by the condition at the place whence the water came—it is obvious that a study of currents must precede any general view of the distribution of marine forms.

Regard must be had not merely to the superficial currents indicated in fig. 1, but also to the movements of the deeper layer. Ice melting at the poles, together with polar precipitation of hail, snow and rain, yields large quantities of water of low salinity and very low temperature; this water sinks under the warmer saltier surface water drifted from lower latitudes, and, creeping slowly north and south from the poles, covers the bottom of all the great open oceans at very uniformly low temperatures (in some cases as low as 30° F.). Between surface and bottom the temperature gradually decreases (except where affected by local circumstances), and in the middle layers the existence of slow currents is suspected. The cold bottom water wells up to the surface in certain areas, replacing the surface water drained away by currents, notably to the westward of the great land masses. Ocean water is remarkably uniform as regards its contained salts and gases, and it does not seem likely that we can look to these to explain the facts of distribution. In its temperature, on the contrary, there is enormous variation. While the bottom water of the ocean is very cold, and the middle-water of a more or less intermediate temperature, the surface water, according as it has drifted from the equator polewards or in the reverse direction, has a mean annual temperature somewhere between 84° and 30° F., losing or gaining heat on its way. In the case of narrow or "closed" seas, and near land masses, sea-water does not exhibit that uniformity of composition which characterizes the open ocean; but even in such cases the temperature is largely influenced by adjacent currents, and, though less obviously than in the open ocean, seems to be a very important agent in distribution.

The fauna of the sea is divisible into the plankton, the swimming or drifting fauna which never rests on the bottom (generally taken now to include E. Haeckel's nekton, the strong swimmers, such as fish and cephalopods), and the benthos, which is fixed to or crawls upon the bottom. These groups require a further subdivision according to depth—the more necessarily since, to some zoologists, any water over 100 fathoms is "deep," or even "abyssal." It is simplest to begin with the benthos. From

![Diagram of the Atlantic Ocean, showing the Main Surface Currents (some are seasonal only): the corresponding Indian and Pacific currents are cited in parentheses; they are rarely strongly marked as in the Atlantic.](image)

1. Counterequatorial (also 1' Pacific and Indian).
2. North Equatorial (also Pacific).
3. Gulf Stream proper (Japan Stream).
5. Mozambique Current (curved off Cape Agulhas).
6. Labrador Current (Kamchatka Current).
7. Falkland Current.
9. South Atlantic Drift, ill defined (South Pacific Drift).
13. Antarctic Circumpolar Drift. 7', its northerly branches on the west sides of Africa and South America.

The shore seawards we may distinguish several zones. Even the tidal zone, between high and low water-mark, is subdivisible by its fauna and flora. There generally follows on this a very gentle slope to the depth of about 100 fathoms, locally subdivisible into many lesser zones. It has been termed the continental shelf or littoral zone, not very appropriately, since it occurs round many oceanic islands, and even away from any land. In this zone, if near land, fall to the bottom the heavy materials produced by land waste and river drainage. The fauna of this zone, generally very well characterized, may be
PLANKTON

distinguished as the epibenthos. As with the shallowest or tidal zone, its nature varies much more according to latitude and the character of the coast than the deeper zones. Everywhere, however, the epibenthic fauna is exposed to certain definite environmental conditions, as compared with a deeper fauna: namely, a high or fairly high temperature (except near the poles); a fairly good light, with its important consequence, a vegetable basis of food supply; tide and current to distribute the larvae to a suitable habitat, which the varied nature of the bottom near land is likely to furnish. Passing farther seawards, we find a steeper slope to about the 500-fathom line, the so-called continental slope. In this zone the environment is absolutely

Fig. 2.—Mean Annual Surface Isotherms of the Atlantic. (After Buchan, "Challenger" Report on "Oceanic Circulation.") On the north-east and south-west sides they are deflected polewards by the warm North Atlantic Drift and Brazil Current; on the south-east and north-west sides equatorwards by the cold Labrador and Benguela Currents. Note the markedly different latitudes of the same isotherms east and west of South America and Africa; also the effect of the Falkland Current against the Brazil Current.

different. The water, no longer subject to seasonal variations of temperature, or to direct sunlight, is cold, and of a nearly uniform annual temperature (200 fathoms, 44°F.). Light has disappeared from all but the shallower part, and with it plant life; tide and current are no longer felt. To the latter fact is due, however, a great part of the food supply, which maintains in this zone an abundant fauna: a great quantity of organic matter, brought down by river action, produced by disintegrated sea-weed, and due to the death of surface organisms, together with the finer clayey materials of land waste, settles to the bottom in quiet water, near the 100-fathom contour, thus making the mud-line the richest feeding-ground in the ocean (Murray). The mud-line is the real upper limit of this zone; it typically begins at about 100 fathoms, but may begin at 5 to 20 fathoms in deep sheltered firths, or be pushed down to 300 fathoms where currents are strong. The fauna of this zone may be termed the mesobenthos; it is not so abundant, nor so sharply characterized, as the epibenthos, and yet is sufficiently distinct to deserve at any rate a provisional name. Another

difference of condition between epibenthos and mesobenthos is the pressure of the water; at a depth of 500 fathoms this is, roughly speaking, half a ton to the square inch. It is very doubtful whether this enormous pressure makes the slightest difference to marine invertebrates, the tissues of which are uniformly permeated by fluids, so that the pressure is uniform in every direction; but animals with free gases naturally require time to adjust the gas-pressure when altering their levels. As regards the penetration of light, assimilative rays useful to plant life probably do not reach beyond 150 fathoms. Photographic rays have been detected as low as 220 fathoms, and if any light penetrate beyond this depth, it will consist only of blue, violet and ultra-violet rays: it has been suggested that the red colour prevalent in many deep-sea animals may be a screen from these hurtful rays. Below the 500-fathom line the ocean bottom exhibits almost uniform conditions everywhere, varied only by the character of the bottom deposit and the amount of food supply. In this zone, which extends from about 500 fathoms to the greatest depths (which may in some cases exceed 3000 fathoms, or more than 1.5 m.), the temperature at any given point is uniform throughout the year, and is always very low; the mean at 2200 fathoms is 9° F.; at greater depths and in special circumstances less than 3° F. has been recorded. The darkness is probably absolute; for food the animals are dependent upon each other and upon the incessant rain of dead plankton from higher levels; the pressure may be anything between half a ton and five tons per square inch. To the fauna which lives in these remarkable circumstances the name hypobenthos may be applied.

That each of the three benthic groups is well characterized by a special fauna is shown by the following table, out of the total numbers of species captured by the "Challenger" at seventy stations in these three zones—

<table>
<thead>
<tr>
<th>Species confined to this Zone</th>
<th>Species occurring in other Zones</th>
</tr>
</thead>
<tbody>
<tr>
<td>Epibenthos</td>
<td>91%</td>
</tr>
<tr>
<td>Mesobenthos</td>
<td>74%</td>
</tr>
<tr>
<td>Hypobenthos</td>
<td>61%</td>
</tr>
</tbody>
</table>

Out of the 25% of its species which the mesobenthos shares with other zones, 59% occur also in the epibenthos, about 40% in the hypobenthos, the mesobenthos, therefore, on these figures may be taken to consist of 74% of peculiar species, 15% shared with the epibenthos, 10% with the hypobenthos. Speaking of the benthos as a whole, it may be said that the following statement holds good. The number of individuals, the proportion of species to genera, and the number of individuals of a given species, all decrease with increasing depth. Animal life also tends to diminish with increasing distance from land; this may be partly due to the greater food supply near land, partly to the fact that population is obviously thinnest on the advancing fringe of a migration.

The plankton can be subdivided into at least two groups. The fauna to which light and warmth are more or less necessary, which feeds either upon plants or upon organisms nearly dependent upon plant life, may be termed the epiplankton. This fauna is capable of a good deal of vertical movement upwards and downwards, the causes of which are still obscure, but most of its members seem rarely to descend lower than about 100 fathoms. Below this depth the fauna may be called the mesoplankton. In every area this appears to have its peculiar species, but the careful study by opening and closing tow-nets of the distribution of the mesoplankton is of so recent a growth that no statistics, such as we have of the benthos, is available. It is now generally admitted that the mesoplankton extends to the lowest depths yet searched (2730 to 2402 fathoms, Valdivia); but the number of specimens decreases rapidly after 200 fathoms, and below 1000 fathoms very little is known. The conditions of light, temperature, pressure, &c., are practically those of the corresponding depths of the benthos; as regards the food, however, the mesoplankton can only depend on intercepting dead organisms which are falling from higher bottoms, or on capturing the scanty zooplankton there. It is possible that the plankton immediately over the bottom may prove to be sufficiently distinct to be separately classed as hypoplankton.

The main subdivisions of the marine fauna having thus been briefly sketched, it is advisable to consider them in somewhat more detail. The epibenthos is obviously that fauna to which, except in polar regions, light and warmth are necessary; and the absence of these at greater depths is
probably the chief barrier to its vertical extension; the food
supply is sufficiently plentiful in, at any rate, the upper parts
of the mesobenthic zone to prevent no obvious barrier. The
chemical constitution of the water (except to animals in brackish
water near river mouths) and the pressure appear to exert little
or no influence; and only those species which attach themselves
to clean hard substances would be repelled by the mud-line.

The chief barrier to a horizontal extension of the epibenthos
is undoubtedly temperature. As an example of its distribution
may be taken the Gastropod and Lamellibranch Molluscs, as
groups of which the distribution has been studied for many years
by specialists. The shallow-water species fall into provinces
and a comparison of figs. 1 and 3 shows at once the profound
influence upon them of the great currents. Taking the Atlantic
Ocean, we find the Arctic species, tempted southwards by the
cold Labrador Current, repelled northwards by the warm
North Atlantic Drift. The Boreal or sub-Arctic species, many
of which are identical on both sides of the ocean (2 and 2', fig. 3),
lie much farther southwards on the west than on the east side,
from the same causes. The warm-water molluscs of West
Africa (5) are cut off from those of the east side (7) by the cold
water from the great easterly Antarctic Drift, which impinges
on the Cape, giving it a special fauna (6). On the South American
coasts the tropical and temperate fauna reach respectively
to 28° S. and 45° S. on the east coast, owing to the warm Brazil
Current; but the corresponding groups on the west coast only
to 5° S. and 37° S., being kept back by cold upwelling and Hum-
boldt's Current. This influence is visible in individual species
as well as in the facies of a fauna: *Purpura lapillus*, a temperate
form, reaches on the east side of the Pacific to 24° N. and on
the East Atlantic to 32° N.; but on the West Pacific only to
41° N. and the West Atlantic to 42° N., being repelled by the
Japan stream (and other warm currents of the south-west
monsoon) and Gulf Stream respectively.

But while some species may be confined to a bay, others to
a province, others to an ocean, there are cosmopolitan species
which either vertical or horizontal barriers, or both, fail to
restrain. In relation to temperature the wide-ranging species
are termed *eurythermal*, the limited, *stenothermal* (Moebius);
the terms are useful to record a fact, but are not explanatory.
It seems to be the case that to every organism is assigned a
minimum temperature below which it dies, a maximum tempera-
ture above which it dies, and an optimum temperature at
which it thrives best; but these have to be studied separately

---

for every species. Similarly, in regard to depth, species
have been classed as *eurybathic* and *stenobathic*, but, since
increased depth practically means diminished temperature, these
are probably merely expressions of the same fact in another
form. That an Arctic shallow-water species should stretch
to considerable depths is not surprising, but it is remarkable
to find such forms as, for example, *Venus mesodesma* on a New
Zealand beach at 55° F. and in 1000 fathoms at 37° F. off Tristan
d'Acunha. The provinces of zoological distribution, like the
geographical divisions of mankind, must be taken merely to
indicate the facies of a well-characterized fauna, not to imply
the restriction of all its habitants to that area.

In considering the effect of temperature (and this applies
to plankton as well as to benthos down to 100 fathoms), attention
must be directed not only to the question of general warmth or
cold as expressed by the mean annual temperature, but also
to the range between the annual extremes: these ranges of
variation have been carefully mapped by Sir J. Murray (*Geog.
*Journ. xii. 113; compare ibid. xiv. 34). Still more important
to the death-rate than these is the suddenness with which such
variations occur: many animals are known to endure great
extremes of heat and cold if exposed to them gradually, but to
suffer to rapid alterations of temperature. Hence the frontier
districts (*Mischgebiete*) between opposing currents are charac-
terized by a heavy death-rate, and constitute marked barriers.
A conspicuous instance of such a barrier in distribution is afforded
at the Cape. The warm Mozambique Current, with a south-
westernly direction off Natal, meets a north-east branch of the
cold Antarctic Drift, and is beaten back eastwards; a result
of the constant warring of these hot and cold currents is a high
range of sudden temperature variation. Hence the Cape fauna
consists mainly of only such species from neighbouring provinces as can endure high sudden variations; and the district is practically impassable. For example, nineteen species of Echinoids are known from the Cape district. Of these twelve are peculiar to the Indo-Pacific province, which stretches from East Africa to the Sandwich Islands and from Japan to Australia; two species are Southern Ocean forms, all but confined to south of 30° S.; four species are peculiar to the Atlantic Ocean; of these eighteen one does not get past the Cape into the next province; the nineteenth is practically a cosmopolitan (A. Agassiz, "Challenger" Reports: "Echinoida"; compare also C. Chun, Aus den Tiefen des Wellmeeres, pp. 157, 158).

Among the barriers to the horizontal extension of epibenthos must be mentioned a wide deep ocean. The Indo-Pacific fauna ranges from East Africa to about 108° W., stepping from island to island over the Pacific; but this continuity is then broken by 37 degrees of longitude and more than 2000 fathoms of water, and such sessile species as are most molluscs (cf. fig. 3) are unable to reach the American coast. This is presumably due to the fact that the planktonic larvae of epibenthic adults must settle on a suitable bottom within a certain period or die. In spite of the direct set of the currents from Florida to the British Isles, the epibenthos is not uniformly distributed. The similarity of the two Boreal provinces (2 and 4, fig. 3) is to be assigned to a former continuity by way of Greenland, Iceland and Faeroe; a similar continuity, still unbroken, is exhibited by the Aleutian province on both sides of the Pacific. Though larvae cannot cross wide oceans, adults may no doubt traverse great stretches occasionally on floating timber, &c.

This barrier by distance may be instanced in another way. In the Arctic regions land masses are continuous or contiguous, and there are many circumpolar species, as, for example, Rhynchonella psilacea; towards the South Pole the southern continent is almost ice-bound, and the available land consists only of the tips of the continents and of the few oceanic islands. Hence few if any littoral species are circumpolar. For example, not a single littoral Ophiurid surrounds the South Pole, but five or six species are circumpolar in the northern hemisphere.

Taking next the mesobenthos and hypobenthos, living at depths where temperature is constant and current practically negligible, there appears theoretically to be no reason why an organism which can thrive at 500 fathoms should not have a world-wide distribution over the bottom of all oceans. Yet this is not often, although occasionally, known to be the case; and although perhaps, speaking generally, hypobenthic species have wider ranges than epibenthic, still they also seem to be limited. It must, however, be remembered that the ocean is large, deep hauls of trawl or dredge few, and individuals at great depths scattered, so that too much stress must not be laid on this point. The "Challenger" results seem to allow of at least one generalization: the deeper the fauna, the wider its range. This is shown by the following table of the "Challenger" benthos: the first column gives the number of benthos species captured at depths indicated in fathoms by the second column; the percentage of these species which is known to have been captured between the tropics, as well as south and north of the tropics, is shown in the third column:

We can only guess at the causes of the apparently limited range of many deep-sea types. (a) One of these is probably the limited food supply: presumably, with a land fauna, there are as many mouths in a given area as it will support, and an equilibrium of species is maintained which will at least hinder the extension of any one. For food the bulk of the deep-water fauna is dependent upon the rain of dead organisms falling from higher levels, these, slowly disintegrating (probably under chemical, not bacterial, action), seem to form with the bottom deposit a kind of nitrogenous ooze, through which many deep-sea organisms slowly swallow their way, as an earthworm goes through earth extracting nutrient. (b) Another hindrance to the extension of many deep-sea species is that they are holobenthic, that is, do not pass through a free-swimming larval stage; the means of dispersal is therefore regulated by the animal's own power of locomotion. Generally speaking, as might be expected, the freely-moving hypobenthos, fish and crustacea, have the widest ranges, and even these are not helped by currents, as are epibenthic or planktonic forms. The larval history of deep-water forms is, however, unfortunately obscure. (c) Lastly, extension of area of a species being at best difficult in deep water for non-swimmers, the place and date of their first migration must be taken into account; forms which have comparatively recently adopted deep-water life cannot be expected to have spread far from their original centre. As regards this point, in the first place, it is with migration, not with local evolution, that we have to deal: no classes and orders, only a few families and genera, rarely sub-orders, are peculiar to the hypobenthos; that is, are found only below the mesobenthic zone. Two divisions, the sea lilies and the echinoids, are especially in this respect; the former consist of rather widely separated genera, the species do not grade into each other, and so is often the case in the epibenthos; and evolution could hardly have produced these species and genera under the uniformity of their present environment. This migration downwards from the mud-line has no doubt occurred all over the world, notably in the Southern Ocean, if we may judge by the richness of the deep-water fauna there to-day; probably also largely in Arctic and sub-Arctic regions, less so in tropical and temperate zones. As to the date of migration, the following fact seems to show that it is of comparatively recent origin, and is indeed still in progress: taking the "Challenger" species from the epibenthos, from the mesobenthos, and then from zones of 500 fathoms down to 2500, each zone shares a larger percentage of species with the zone above it than with that below it (except in one case where they are nearly equal). But it is not to be supposed that all our present-day deep-water forms began their migration simultaneously, and we can say with fair certainty that migration to deep water did not begin before the close of the Mesozoic era. Had it begun earlier, and typical Mesozoic and even older forms, with their peculiarities, at great depths: so far is this from being the case that the most venerable animals of to-day—Lingula, Amphipus, Limulus, 75% of Crinoids, 90% of Brachipoda, &c.—are epibenthic or mesobenthic. On the other hand, it is extremely likely that the Cretaceous epoch marked the commencement of migration. The hexactinellid sponge Echinoidea are known to have lived in quite shallow water at the date of deposition of the Inferior Oolite; to-day none occur at a depth less than 95 fathoms; and as only two genera are known from the shallow Tertiary deposits, it would seem that the migration began about Cretaceous times ("Challenger" Reports: "Hexactinellida," F. E. Schultze). In 1881 (A. Agassiz, "Challenger" Reports: "Echinoida") 105 living genera of Echinoidae were admitted; of these 23% were known from Cretaceous but not from Tertiary deposits, 35% from Tertiary but not Cretaceous, and 40% as Recent only. The species of Cretaceous genera constituted only 29% of the epibenthic Echinoids, 44% of the mesobenthic, and no less than 55% of the hypobenthic. These species of Cretaceous genera are distributed fairly evenly over all the zones, but 72% of the species of Tertiary genera and 55% of the Recent forms were confined to the epibenthos. As out of the twenty-five living genera known from the Cretaceous only seven are known also from Jurassic deposits, it is obvious that the close relationship is between Cretaceous and hypobenthos, rather than between any other geological and bathymetric horizons. Other instances, such as that of the Eryonidae, seem to point to similar conclusions.

Excepting the essential air-breathers, practically every phylum and class and most orders are represented in the benthos. The
epibenthos of warm seas appears to be especially wealthy in such forms as secreting heavy calcareous skeletons; but in colder waters, among the epibenthos of polar or sub-polar regions, and the hypobenthos everywhere in open oceans, the predominant forms are those which exhibit little or no calcareous secretion: even the apparent exceptions, Madreporaria and Echinodermata from great depths, tend to develop slighter skeletons than their warm-water congeners. The following table will serve to illustrate this point, and to give an idea of the composition of the epibenthos of cold and warm seas and of the hypobenthos: the figures are the percentages of total species captured in each locality by H.M.S. “Challenger,” the balance being made up by few specimens in scattered groups:

While the Madreporaria represent only 33% of the species at the tropical station, it must be remembered that they probably made up 60% or more of the weight.

The epibenthos is dependent either directly or proximately upon light, warmth and the presence of plant life. The wealth of minute organisms near the surface is inconceivable to those who have not seen the working of a two-net: it may be gauged by the fact that a single species is sometimes present in such quantities as to colour the sea over an appreciable area, and by the estimate that the skeletons of epibenthon from a square mile of tropical ocean a hundred fathoms deep would yield 16 tons of lime. In the tropics the wealth of species, and towards the poles the number of individuals of comparatively few species, are characteristic of the latitudes. In temperate and tropical regions there is a great difference between the epibenthon near land and that far out at sea; the former is termed “near-shore,” it extends, roughly speaking, as far out as the mud-line, and is characterized by the predominance of what may be termed hemibenthic forms, that is, benthic forms with a planktonic larval stage (Decapoda, Polychaeta, &c.), and with a planktonic phase (metagenetic Medusea). The horizontal barriers to the neritic plankton are practically those mentioned as governing the epibenthon; indeed, it would seem that the distribution of hemibenthic adults is determined by that of their more delicate larvae. Special conditions of wind and current may of course carry into the neritic zone forms which are characteristic of the open sea, and vice versa. In the neritic epibenthon of polar waters the larvae of hemibenthic forms are almost absent; indeed, the development of cold-water benthos, whether shallow or abyssal, appears to be in most cases direct, this is, without a larval metamorphosis. The epibenthon of the open sea is described as oceanic; it consists almost entirely of holoplanktonic forms and their larvae. The chief barrier to horizontal distribution, here as elsewhere, is doubtless temperature. For example, through the reports of the “National” cruise (German Plankton Expedition) runs the same story; one fauna characterized their course from Shetland to Greenland and Newfoundland, another the traverse of the Gulf Stream, Sargasso Sea and the Equatorial Currents. The influence of temperature may be gauged in another way: where hot and cold currents meet, occur “frontier” districts, in which the respective organisms are intermingled, and can only exist till their maxima or minima are reached. Well-marked examples of such districts occur off New Jersey (Gulf Stream and Labrador Current), in the China Sea (warm currents of the south-west monsoon in Kamchatka Current), in the Faeroe Channel, south of the Cape (Cruising of the Agulhas Current); in some of these the range of variation amounts to as much as 50° F. in the year, with the result of a colossal death-rate of the plankton, and its corollary, a rich bottom fauna, for which food is thus amply supplied. The majority of the oceanic epibenthon appears to be steno-thermal; for example, few components of the well-characterized fauna of the Gulf Stream and Sargasso Sea ever reach the British shores alive, although, if current and salinity were the determining factors and not temperature, this fauna should reach to Shetland, and even to Loften. It will only be possible to make satisfactory distributional areas for these oceanic forms by such systematic traverses as that of the “National”; at present it would seem that adjacent species have such different maxima and minima that every species must be mapped separately (compare the distribution-maps of the “National” Plankton Expedition). Some members of the epibenthon are, however, extraordinarily eurythermal and eurybathic; for example, Calanus finmarchicus ranges from 76° N. to 52° S. (excepting perhaps for 10° each side of the equator), and is apparently indifferent to depth.

In the first hundred fathoms at sea the fall of temperature is gradual and slight, and forms practically no hindrance to the migration of the oceanic epibenthon—the alleged rise and fall of almost the entire fauna. Roughly speaking, the greatest number of animals is nearest the surface at midnight; but different species sink and rise at different times, and to or from different depths. Apart from this diurnal oscillation, unfavourable conditions at the surface send or keep the fauna down in a remarkable way: for example, in the Bay of Biscay few organisms are to be found in the first fathom in bright sunlight, but on a still, hot day the next few fathoms teem with life; yet after a few minutes’ wind or rain these upper layers will be found almost deserted. This leads to the consideration of the hydrostatics of the plankton: apart from strong swimmers, the majority contests the tendency to sink either by some means of diminishing specific gravity (increasing floating power) or by increased frictional resistance. The former is generally attained (a) by increase of bulk through development of a fluid secretion of low specific gravity (vacuoles of Foraminifera, Radiolaria, &c.); (b) or of a gelatinous secretion of low specific gravity (Medusae, Chaetopod and Echinoderm larvae, Chaetognatha, Thaliacea), the characteristic transparency of so many oceanic forms is probably attributable to this; (c) by secretion or retention of gases (Phylogynae, Emphion); (d) by development of oil globules (Cephepod, Cladocera, &c.). Increased frictional resistance is obtained by flattening out of the body (Phyllosoma, Sapphirina), or by its expansion into lateral processes (Tomopteris, Glaucom), or by the development of long delicate spines or hairs (pelagic Foraminifera, many Radiolaria, many Chaetopod and Decapod larvae). In many cases two or more of these are combined in the same organism. Notwithstanding the above adaptations, some of which are adjustable, it is difficult to understand the mechanics of the comparatively rapid oscillations of the epibenthon, of which both causes and methods are still obscure.

It will be seen from the distribution of the Thecosomatous Pteropoda—a purely oceanic group—how difficult it will prove to draw distributional areas for classes of epibenthon. P. Pelseneer recognizes in all ten such provinces (“Challenger” Reports: “Zool.” xix., xxii.) and 42 good species: of the latter 1 is confined to the Arctic, 4 to the Antarctic province, but of the remaining 37 species and eight provinces 30% occur in all eight, 15% in seven, and only 35% have as yet been captured in a single province only. The mesoplankton, on the other hand, has only received serious attention during the last few years. In the “Challenger,” open nets towed at various depths seemed to show the existence of a deep-water plankton, but this method gives no certain information as to the horizon of capture, the nets being open in their passage down. C. Chun

724

PLANKTON
constructed the first efficient net which could be opened and shut at known depths, using a propeller mechanism (Bildes Zool. vol. i); and he improved his original pattern for the “National” and “Valdivia” expeditions. The present writer has devised a net, of which the opening and closing are effected from the deck by heavy weights; this has been used successfully on the “Siboga” expedition and in cruises of the “Research” (Proc. Zool. Soc., 1898). W. Garstang has constructed an ingenious net which is useful in comparatively shallow water, but is open to criticism as being too light for depths beyond 100 fathoms; and several other types are in use. The existence of a mesoplankton, that is, of a plankton living between 100 fathoms from the surface and the bottom, has been generally considered as definitely proved by these nets. On the other hand, A. Agassiz, using the Tanner tow-nets, contends that while a mixture of surface and bottom species may occur in a closed sea near land, there is no intermediate fauna in the open ocean between about 200 fathoms from the surface and the bottom; his conclusions, based on negative evidence, have not met with general acceptance. Animals captured below the first hundred fathoms in the open sea (the Mediterranean, for special physical reasons, is on a special footing) are divisible into at least three categories: (1) those which are eurythermal and eurybathic, *e.g.* Calanus finmarchicus; (2) those which, so far as we know, are purely mesoplanktonic and never come to the surface, for example, the Radiolarian family *Tuscarorides*; (3) those which, like some Schisopoda, spend a larval period in the epipelagic, and seek deeper water when adult, rising to the surface, if at all, only at night. But until the publication of the results of expeditions provided with efficient mesoplankton nets, generalizations about this fauna had better be stated with all reserve. There is, however, a certain amount of evidence to show that the mesoplankton includes different organisms in different latitudes; that surface animals of the north and south, unable to spread into the warmer surface water of lower latitudes, there sink into the cooler waters of the mesoplankton; the distributional area of such an organism would be restricted by isotherms or isothermals. As with the hypobenthos, there seems to be no theoretical reason against the universal distribution of the mesoplankton.

When a more systematic investigation of the various horizons has been carried out, many of the present cases of supposed discontinuous distribution will doubtless disappear. There are, however, undoubted cases of discontinuity where physical barriers have cut across a distributional area, an example of which may be cited here. The Isthmus of Panama was apparently only upraised about Miocene time, having been previously an archipelago through which a great circumpolar water current could pass; consequently the benthos of the Panama region shows marked alliance with the Caribbean, with which it was formerly continuous, but practically none with the Indo-Pacific. To the same cause is doubtless attributable the distribution of the Five Decapoda which are characteristic of the deep western basins, which are circumpolar oceanic types, only occasionally littoral: three of these are known only from the Atlantic, one occurs in the Atlantic and Pacific, one in the Atlantic, Pacific and Indian Oceans. The damming of a great circumpolar current by the Isthmus of Panama is probably also responsible for that dislocation of currents which resulted in the present relations of the Gulf Stream and North Atlantic Drift to the Labrador Current, and cut the Atlantic Boreal fauna into two discontinuous districts (2 and 2', fig. 3).

Under the head of discontinuous distribution, the alleged phenomenon known as biparity must be mentioned. In summarizing the work of the “Challenger,” Sir John Murray maintained on the basis of the reports that numerous species occurred in both polar and sub-polar areas which were absent from the tropic. He regarded them as the hardy survivors of a universal fauna which had withstood that polar cooling which set in towards the close of the Mesozoic period (Murray, *Trans. Roy. Soc. Edin.* vol. xxxviii., 1896; G. Pfeffer, *Verh. deutsch. Zool. Gesellsch.* ix. 1899). This view and the facts on which it was based have been acutely contested, and the question is still far from settlement (for lists of the literature see A. E. Ortman, *Am. Nat.* xxviii., 1895, and McGill E. M. Pratt, *Mem. Manchester Soc.* vol. xlv., 1901). As regards the purely epibenthic and sessile fauna, there are a few undoubted instances of actual specific identity; in some classes, however, such as the Echinodermes, this does not appear to hold (Hamburger Magalhaescha Sammelreise; and F. Römer and F. Schaudinn’s *Fauna arctica*); but even in these the general composition of the fauna and the presence of certain identical and peculiar genera seem to point to something more than a mere “convergence” due to similar environment. As regards the plankton of the two polar regions and such epibenthic forms as extend also into deep water, the suggestion has been made that the Arctic and Antarctic benthos and plankton are really continuous by way of deep water in the main oceans, where the organisms can find a suitably low temperature. As an instance of this, C. Chun (Zeit. f. wiss. Meereskunde, 1897) cites Krohnia homala, a characteristic Arctic and sub-Antarctic constituent of the epipelagic and mesoplankton, known only from the mesoplankton in the tropics, but rising to 38 fathoms at 40° S. 26° E. More exact information, such as may be expected from the various Antarctic expeditions, is required to settle this interesting question with its far-reaching corollaries. (G. H. Fo.)

**PLANQUETTE—PLANTEGNET.**

**PLANQUETTE, ROBERT (1850— ), French musical composer, was born in Paris on the 31st of July 1850, and educated at the Conservatoire. As a boy he wrote songs and operettas for café concerts, and sprang into fame as the composer of *Les Cloches de Cornville* (Paris, 1871; London, 1878). In this work he showed a fertile vein of melody, which won instant recognition. There is in his music a touch of pathos and romantic feeling, which, had he cared to cultivate it, would have placed him far above contemporary writers of opéra bouffe. Unfortunately, he did little but repeat the formula which originally made him famous. *Ingres* was composed in 1877, with little success. In 1880 came *Les Voleurs du 32*° which had a long run in London in 1883 as *The Old Guard,* and *La Continiere,* which was translated into English as *Nectarine,* though never produced. In 1882 *Rip van Winkle* was produced in London, being subsequently given in Paris as *Rip,* in both cases with remarkable success. The libretto, an adaptation by H. B. Farnie of Washington Irving’s famous tale, brought out what was best in Planquette’s talent. In 1884 the phenomenon of an opera by a French composer being produced in London previously to being heard in Paris was repeated in *Nell Gwynne,* which was tolerably successful, but failed completely when produced in Paris as *La Princesse Colombe.* It was followed by *La Crémailleire* (Paris, 1883), *Surcouf* (Paris, 1887; London, 1889), *Capitaine Thério* (London, 1887), *La Coccéde tricolore* (Paris, 1892), *Le Tailleman* (Paris, 1892), *Panurge* (Paris, 1893) and *Mam’zelle Quel’sous* (Paris, 1894).

**PLANTEGNET,** a surname conveniently, but unhistorically, applied to the royal line descended from the union of Geoffrey, count of Anjou, with the empress Maud, who are now styled by historians the Angevin house. It was, historically, only a personal nickname of Geoffrey, as was “Beauclerc” of his father-in-law (Henry I.) and “Curtmantel” of his son (Henry II.), and was derived from his wearing in his cap a spig of the brome (genet) plant, “which in early summer makes the open country of Anjou and Maine a blaze of living gold.” When the fashion of personal nicknames passed away, the members of the royal house were usually named from their birthplace, as Thomas of Bretherton, Thomas of Woodstock, Edmund of Woodstock, Edmund of Langley, Lionel of Antwerp and so forth. But Edward I. and his younger brother, the founder of the house of Lancaster, had still nicknames respectively, as “Longshanks” and “Crouchback.” In the later days of the dynasty the surname of Beauclerc was adopted by the legitimate issue of John of Gaunt by Katherine Swynford, but that of Plantergnet was bestowed on Arthur, natural son
of Edward IV., who was created Viscount L'Isle. It appears, however, to have been adopted as a surname by Richard duke of York (father of Edward IV.) some twelve years before his death.

At the death of Geoffrey's grandson, Richard I., the succession was in doubt, John's elder brother Geoffrey having left, by the heiress of Brittany, a son and a daughter. But at that epoch the law of inheritance was in such a case unsettled, and their right was not clear. Arthur's fate is well known, and Eleanor, the daughter, was kept captive till her death in 1421. John's younger son Richard, king of the Romans, left a son Edmund, earl of Cornwall, with whom his line ended; his elder son Henry III. left two sons, of whom the younger was created earl of Lancaster and was grandfather of Henry, earl of Lancaster, whose heiress married John of Gaunt (i.e. Ghent). Edward I., the elder son, was grandfather of Edward III., the marriages of whose numerous children greatly affected English history. Edward his heir, the "Black Prince," left an only son, who succeeded his grandfather as Richard II., on whose death (1399) this line became extinct. Lionel, the next surviving brother of the Black Prince, left an only child Philippa, who married the earl of March, in whose heirs was the right to the succession. But John of Gaunt, the next brother, who had married the heiress of Lancaster and had been created duke of Lancaster in 1364, re-founded the Lancastrian line, which obtained the throne in the death of Richard, and through the deposition of Richard II., to the exclusion of the infant earl of March. His next brother, Edmund Langley, who was created duke of York (1385), founded the Yorkist line, and was father, by a daughter and co-heiress of Pedro the Cruel, king of Castile, of two sons, Edward, second duke, who was slain at Agincourt, and Richard, earl of Cambridge, who by marrying the grand-daughter and eventual heiress of Lionel's daughter Philippa, brought the right to the succession into the house of York.

Between their son and Henry VI. (grandson of Henry IV.) and Edward and Henry, sons and heirs of these rivals, was fought out the dynastic struggle known as "the Wars of the Roses," which proved fatal to several members of both houses. Richard, the son of Richard and Anne Mortimer, became third duke of York (1425), and was made protector of the realm 1454-1455, being finally declared heir to the throne on the triumph of his side in 1460; but he was slain at the battle of Wakefield (Dec. 31, 1460). Of his four sons, Edward, the eldest, became king as Edward IV. within three months of his death; Edward the second was slain in battle; the eldest of their sons, George, the third, duke of Clarence, was put to death in 1478; and Richard, the fourth, duke of Gloucester, became king as Richard III. in 1483 and was slain on Bosworth Field in 1485. King Edward IV.'s two surviving sons, Edward and Richard (the princes in the Tower), had been mysteriously put to death in 1483, so that the only male descendant of the house of York, and indeed of the whole Plantagenet race, was the duke of Clarence's son Edward, earl of Warwick (grandson of "the Kingmaker"), who was imprisoned by Richard III. (his father's younger brother) in 1483, and finally executed on Tower Hill, under Henry VII., in 1499.

Of the house of Lancaster, the only son of Henry VI. was slain after the battle of Tewkesbury (1471), while Edmund (Beaufort) duke of Somerset, a grandson of John of Gaunt, was slain at the first battle of St. Albans (1455), and all his three sons were slain or beheaded. On the death of Henry VI. and his son in 1471, so complete was the extinction of their line that its representation vested in the heirs of the two daughters of John of Gaunt by the heiress of Lancaster, viz. Philippa queen of Portugal, and Elizabeth countess of Huntingdon. But by his second wife, the heiress of Castile, John had left an only daughter, wife of Henry III., king of Castile and Leon, who also left descendants, and from his third but ambiguous union sprang the house of Beaufort, whose doubtful claims to the heirship passed with his great-granddaughter Margaret, by her husband Edmund Tudor, to their son Henry VII. Although Henry was careful to claim the crown in his own right (1485), he soon fortified that claim by marrying Elizabeth, eldest daughter of Edward IV. and rightful heir to the throne. The marriage of their eldest daughter Margaret to James IV. of Scotland in 1503 resulted in the accession of James VI. of Scotland, a century later, as next heir to the throne (see STEWART).

Although no other dynasty has reigned so long over England since the Norman Conquest, the whole legitimate male issue of Count Geoffrey Plantagenet is clearly proved to have become extinct in 1499. Of its illegitimate descendants the house of Cornwall was founded by Richard, a natural son of Richard, king of the Romans and earl of Cornwall, who was ancestor of Lord Cornwells of Fanhope, temp. Henry VI., of the Cornwalls, "barons of Burford," and other families; but the principal house is that which was founded, at a later date, by Sir Charles Somerset, natural son of Henry (Beaufort) duke of Somerset (beheaded 1646), who was created earl of Worcester in 1513, and whose descendant Henry, marquess and earl of Worcester, obtained the dukedom of Beaufort in 1682. From him descend the ducal house, who bear the ancient arms of France and England, quarterly, within a bordure.

(J. H. R.)

PLANTAIN (Lat. plantago), a name given to certain plants with broad leaves. This is the case with several species of Plantago, also and Musa, to all of which the term is popularly applied. The species of Plantago are mostly weeds, with a dense tuft of radical leaves and scapes bearing terminal spikes of small flowers; the long spikes of P. major, when in seed, are used for feeding cage-birds; P. lanceolata, so called from its narrow lanceolate 3-6-ribbed leaves, is popularly known as ribwort; Alisma P. is the water-plantain, so called from the resemblance of its broad ribbed aerial leaves to those of P. major. The tropical fruit known as plantain belongs to the genus Musa (see Banana).

PLANTATION (Lat. plantare, to plant), literally the placing of plants in the ground, hence a place planted or a collection of growing things, &c., particularly used of ground planted with young trees. The term was early applied, in a figurative sense, to the settlement of people, and particularly to the colonization of North America in the early part of the 17th century and to the settlement of Scotch and English in the forfeited lands in Ireland (see below). The practice of sending convicted criminals to serve on the plantations in the colonies became common in the 17th century (see DEPORTATION). These plantations were founded in the United States, numerous songs and Plantation which the term "plantation" is thus particularly applied to estates in tropical or semi-tropical countries; the proprietors of such estates are specifically styled "planters." The negroes on the plantations of the Southern States of North America sang their songs and hymns and danced to tunes which were traditional, and are frequently brought by the first slaves from Africa, but the more generally accepted view is that they were those European hymn and song tunes which the negroes picked up from the revivalist preachers or from the Europeans around them, and adapted to their own strongly marked rhythms, which are certainly of African origin. The earliest song which became familiar to those outside the Southern States was "Jim Crow," sung by Dan Rice, and introduced to England about 1836. The Jubilee Singers," a troupe from Fisk University, Nashville, Tennessee, toured the United States and Europe in 1871; but the great popularity of the negro songs and dances, and the traditional instruments, the bones and tambourine (the banjo was not originally used by the genuine negro), was due to the so-called "negro minstrel" troupes, of which the best known in England were Christy's Minstrels, whence the generic name of Christy Minstrels, and later of the Moore and Burgess troupe at St. James's Hall, London, started in 1862 and finally dissolved in 1904.

The best collection of genuine "plantation songs" and their words is Slave Songs of the United States (New York, 1871); see also
PLANTIN

Plantation of Ulster.—The Irish rebellion, which had disturbed Ulster during the closing years of Elizabeth's reign, was followed under James I. by further trouble, due partly to the inability of the English government to understand the system of land ownership prevalent in Ireland. At this time the chief offenders against the authority of England were the earls of Tyrconnell and Tyrone, but in September 1607 these once powerful nobles fled from the country. The English lawyers declared that the extensive estates which they held, not in their personal capacity, but as the heads respectively of the tribes of O'Neill and O'Donnell, had become the property of the English crown; and the problem which now confronted James I. and his advisers was what to do with the land, which was much too large to be cultivated properly by the scanty population living thereon. The idea of a plantation or colonization of Ulster, which was put forward as an answer to this question, is due mainly to Sir Arthur Chichester, the Irish lord deputy; its object was to secure the better cultivation of the land and to strengthen the English influence in Ulster by granting estates to English and Scottish settlers. Chichester proposed that the native inhabitants should be allowed to occupy as much land as they could cultivate, for he said, "that many of the natives in each county claim freehold in the lands they possess, and albeit these demands are not justifiable by law, yet it is hard and almost impossible to displace them." Even if this advice were carried out on a generous scale, the deputy considered that there would be abundance of land to offer to colonists, and also to reward the class of men known as servitors, those who had served the English king in Ireland. He submitted his ideas to Sir James Ley and Sir John Davies, two of the ministers of James I.; they reported to the English privy council, which signed its approval, and after the question had been illuminated by Bacon's great intellect, a committee was appointed to make the necessary arrangements. But those responsible for the plantation made one cardinal mistake, a mistake which was to cost the country much in the future. They rejected Chichester's idea of allotting land to the natives on a liberal scale, preferring to turn them out and to parcel out the whole of the forfeited district.

The forfeited lands lay in six counties, Tyrone, Donegal, Armagh, Fermanagh, Cavan and Crolaine (Londonderry), and the scheme for the plantation having been drawn up, the necessary survey began in May 1609. This was very inaccurate, but it served its purpose. The land was divided into three sections. One block was set apart for English and Scottish settlers, who were not to be allowed to have any Irish tenants; another was allotted to the servitors, who might have either English or Irish tenants; and a third was reserved for the Irish. Applications were then entertained from those willing to take up the land, and under Chichester's direction the settlement was proceeded with. The land was divided into portions of 1000, 1500 and 2000 acres, each colonist undertaking in return for his grant to build a castle or a walled enclosure, and to keep, train and arm sufficient men for its defence. Moreover he must take the oath of supremacy to James, and must not alienate his estate to an Irishman. He was given two years in which to do the necessary building; during this period he was freed from paying rents, but afterwards he must pay a quit-rent to the Crown. A scale of rates was also determined, the native Irish paying at a higher rate than the English and Scottish settlers. Out of the forfeited lands provision was made for the maintenance of churches and schools, which were to be erected in conformity with the scheme.

The work progressed very slowly and much of the building was not even begun within the required time. Then in 1611 James I., who had from the first taken a lively interest in the plantation, sent Lord Carew to report on it. Carew's inspection did not reveal a very favourable condition of affairs, and in 1615 Sir Josiah Bodley was sent to make a further report about the progress of the work. A third report and survey was made three years later by Nicholas Fynnar, who found in the six counties 17,925 British families, with 62,155 men capable of bearing arms. He said that even on the lands occupied by the colonists the cultivation of the soil was still very much neglected. The words spoken by Bacon in 1627 with reference to the plantation had come true. "Take it from me," he said, "that the bane of a plantation is when the undertakers or planters make such haste to a little mechanical present profit, as disturbeth the whole frame and nobleness of the work for times to come." Another survey took place in 1622, when various changes were suggested, but no serious alterations were made. On the whole the plantation had been a failure. Very few of the settlers had carried out their undertaking. In many cases the Irish had remained on the land allotted to the colonists, living under exactly the same conditions as they had done before the plantation, and holding on "whether the legal landlords liked it or not." As actually carried out the plantation dealt with 511,465 acres. Two-fifths of this was assigned to British colonists, being divided about equally between Englishmen and Scotchmen. Rather more than one-fifth went to the Church and about the same amount to the servitors and the natives. The best settlers were English and Scotchmen, although their tendency to marry with the Irish was noted and condemned during the early years of the settlement.

An important part of the plantation was the settlement of the county of Crolaine by the corporation of the city of London. Receiving a grant of practically the whole of the county the corporation undertook to spend £50,000, and within two years to build 200 houses in Derry and 100 in Crolaine. This was the most successful part of the settlement, and to it Londonderry owes its present name.

The expulsion of the Irish from the land in which by law and custom they had a certain proprietary and hereditary right, although not carried out on the scale originally contemplated, naturally aroused great indignation among them. Attacks on the settlers were followed by reprisals, and the plantation may fairly be regarded as one of the causes which led to the terrible massacre in Ulster in 1641. During Elizabeth's reign a scheme for the plantation of Munster was considered, and under Charles I. there was a suggestion for the plantation of Connaught, but eventually both were abandoned.

The "Orders and Conditions of Plantation" are printed in Walter Harris's Hibernica (Dublin, 1770); and in George Hill's Historical Account of the Plantation in Ulster, 1608-1620 (Belfast, 1877). See also S. R. Gardiner, History of England (1899), vol. 1.; and R. Bagwell, Ireland under the Stuarts (1909), vol. 1.

PLANTIN, CHRISTOPHE (1514-1586). French printer, was born in a village near Tours (probably Saint-Avertin). He learned bookbinding and bookselling at Caen, and, having married in that town, settled in 1549 as bookbinder in Antwerp, where he was soon known as the first in his profession. A bad wound in the arm seems to have been the cause that first led him (about 1555) to apply himself to typography. The first known book printed in his office was La Institutione di una fanciulla nata nobilmente, by J. M. Bruno, with a French translation, and this was soon followed by many other works in French and Latin, which in point of execution rivalled the best printing of his time, while the masters in the art of engraving then flourishing in the Netherlands illustrated many of his editions. In 1562, Plantin himself being absent in Paris, his workmen printed an octavo edition of the Bible, one of the finest ever seen, and sold. It seems, however, that he recovered a great deal of the money, and in 1563 he associated himself with some friends to carry on his business on a larger scale. Among them there were two grand-nephews of Dan. Bomberg, who furnished him with the fine Hebrew types of that renowned Venetian printer. His editions of the Bible in Hebrew, Latin and Dutch, his Corpus juris, Latin and Greek classics, and many other works produced at this period are renowned for their beautiful execution and accuracy. A much greater enterprise
PLANTS

was planned by him in those years—the publication of a Biblia polyglotta, which should fix the original text of Old and New Testaments on a scientific basis. In spite of clerical opposition he was supported by Philip II, king of Spain, who sent him the learned Benedictus Arias Montanus to take the leading part in the work of editorship. With his zealous help the work was finished in five years (1560–1563, 8 vols. folio). Plantin earned little profit, but received the privilege of printing all liturgical books for the states of King Philip, and the office of "prototypographus regius." Though outwardly a faithful son of the church, he was till his death the partisan of a mystical sect of heretics; and it is now proved that many of their books published without the name of a printer came from his presses together with the missals, breviaries, &c., for the Roman Catholic Church.

Besides the polyglot Bible, Plantin published in those years many other works of note, such as editions of St Augustine and St Jerome, the botanical works of Dodonaeus, Clusius and Lobelius, the description of the Netherlands by Guicciardini, &c. In 1575 his printing-office reckoned more than twenty presses and seventy-three workmen, besides a similar number that worked for the office at home. But in November 1576 the town was plundered and in part burnt by the Spaniards, and Plantin had to pay an exorbitant ransom. He established a branch of his office in Paris; and when in 1583 the states of Holland sought a typographer for the newly erected university at Leiden, he left his much reduced business in Antwerp to his sons-in-law John Moerendorf (Moretus) and Francis van Ravelingenhoven (Raphelengius), and settled there. When in 1585 Antwerp was taken by the prince of Parma and affairs became there more settled, he left the office in Leiden to Raphelengius and returned to Antwerp, where he laboured till his death on the 1st of July 1589. His son-in-law, John Moretus, and his descendants continued to print many works of note "in officina Plantinaria," but from the second half of the 17th century the house began to decline. It continued, however, in the possession of the Moretus family, which religiously left everything in the office untouche, and when in 1876 the town of Antwerp acquired the old buildings with all their contents, for 1,200,000 francs, the authorities were able with little trouble to create one of the most remarkable museums in existence (the Musée Plantin, opened August 19, 1877).

PLANTS. In the most generally used sense, a plant is a member of the lower or vegetable order of living organized things; the term is also popularly applied to the smaller herbaceous plants, thus excluding trees and shrubs. The early use of the word is for a twigs, shoot, cutting or sapling, which was the meaning of Lat. planta (for plant, the root being that seen in planus, flat, cf. Gr. planer, broad; planta thus meant a spreading shoot or sucker). Other meanings of "plant" are derived from the verb "to plant" (Lat. plantare, to fix in position or place). It is thus used of the fixtures, machinery, apparatus necessary for the carrying on of an industry or business, and in colloquial or slang use, of a swindle, a carefully arranged plot or trap laid or fixed to deceive; cf. also plantation. In the following sections the botanical sense of the word is followed, the term being used generally as opposed to "animals."

Classification of Plants

Some account of the history of plant classification and the development of a natural system in which an attempt is made to show the actual relationships of plants, is given in the article Botany. The plant world falls into two great divisions, the higher or flowering plants (Phanerogams), characterized by the formation of a seed, and the lower or flowerless plants (Cryptogams), in which no seed is formed but the plants are disseminated by means of unicellular bodies termed spores. The term Cryptogam is archaic, implying a hidden method of reproduction as compared with the obvious method represented by the flower of the Phanerogams with the aid of the microscope it is, however, easier to follow the process of fertilization in many Cryptogams than in the flowering plants. These two great divisions are moreover of unequal value, for the Cryptogams comprise several groups differing from each other by characters as marked as those which separate some of them from the Phanerogams. The following groups or sub-kingdoms are those which are now generally recognized:

- Cryptogams
  - Thallophyta
  - Bryophyta
  - Phanerogams
  - Spermatophyta

Thallophyta are the mostly lowly organized plants and include a great variety of forms, as, for instance, a thallus or a mass of a single cell or a number of cells forming a more or less branched thallus. They are characterized by the absence of that differentiation of the body into root, stem and leaf which is so marked a feature in the higher plants, and by the simplicity of their internal structure. Both sexual and asexual reproduction occur, but there is usually no definite succession of the two modes marking that alternation of sexual generation (gametophyte) and asexual generation (sporangia) characteristic of the higher plants. Cryptogams have in the present day become so diversified that it is now only possible to indicate the most general features of the main groups. The thallus, the more or less flattened part of the plant, is generally a one-natured one, and a sketch of the system which better expresses the relationships between the various subdivisions is given here. It has however been deemed advisable to retain the older groups as far as possible, so that here and there a distinction is made from the present-day classification. The study of phylogeny has suggested fourteen classes arranged in the following sequence: (1) Bacteria; (2) Cyanophyceae (Blue-green algae); (3) Filamentous (Mycymocytes, Mucilaginose fungi); (4) Peridiniaceae; (5) Conjugatae; (6) Chlorophyceae (Chlorophyta); (7) Cryptogams; (8) Chlorophyceae (Green Algae); (9) Chromophyta (Red Algae); (10) Rhodophyceae (Red Algae); (11) Eumycetes (Fungi); (12) Bryophyta (Algal fungi); (13) Phanerogams; (14) Spermatophyta (Brown Algae). Bacteria (see Bacteria) and Algae (see Algae), which are often grouped together as Schizophyta, are from points of view of both structure and reproduction extremely simple organisms, and stand apart from the remaining groups, which are presumed to have originated directly or indirectly from the flagellate, a group of unicellular aquatic organisms combining animal and plant characteristics which may be regarded as the starting-point of unicellular Thallophytes on the one hand and of the Protozoa on the other. The Protozoa include a group of the Flagellatae, Chlorophyceae and Phaeophyceae show an obvious connexion with the Flagellatae; the Peridiniaceae may be regarded as a further developed branch; the Conjugatae and Diatomaceae may be considered to be derived from the Green Algae, while the remaining Fungi, the Eumycetes, appear to have sprung from the same stock as the Rhodophyceae (see Fungi). Owing to the similarity of structure and mode of life of these latter, the Thallophyta are sometimes considered as a distinct group, but the Thallophyta, Chlorophytae and Phaeophyceae show an obvious connexion with the Flagellatae; the Peridiniaceae may be regarded as a further developed branch; the Conjugatae and Diatomaceae may be considered to be derived from the Green Algae, while the remaining Fungi, the Eumycetes, appear to have sprung from the same stock as the Rhodophyceae (see Fungi). Owing to the similarity of structure and mode of life of these latter, the Thallophyta are sometimes considered as a distinct group, but the Thallophyta, Chlorophytae and Phaeophyceae show an obvious connexion with the Flagellatae; the Peridiniaceae may be regarded as a further developed branch; the Conjugatae and Diatomaceae may be considered to be derived from the Green Algae, while the remaining Fungi, the Eumycetes, appear to have sprung from the same stock as the Rhodophyceae (see Fungi). which remains always attached to the gametophyte from which it derives the whole or part of its nourishment.

The Ferns and fern-like plants (see Pteridophyta) have on the other hand a well developed independent sporophyte which is distinct from, leaf and stem, from the gametophyte, the internal structure including true vascular bundles. In general structure they approach the Phanerogams with which they form collectively the Vascular Plants as contrasted with the Cellular Plants (Thallophyta). In the Pteridophyta the gametophyte is a small thalloid structure which shows varying degrees of independence affording an interesting transition to the next group.

Spermatophyta are characterized by an extreme reduction of the gametophytic structure and the plant is protoplast. The sporophyte is the plant proper and is differentiated into stem, leaf and root, which show a wonderful variety of form; the internal structure also shows increased complexity and variety as compared with the other group of vascular plants, the Pteridophyta. The sporophylls, and in the Pterido-

PLANTS

ANATOMY

the plural form. Among the gametophytes the plant is protoplast. The sporophyte is the plant proper and is differentiated into stem, leaf and root, which show a wonderful variety of form; the internal structure also shows increased complexity and variety as compared with the other group of vascular plants, the Pteridophyta. The sporophylls, and in the Pteridophyta, are thus land plants par excellence and have, with the few exceptions cited, lost all trace of an aquatic ancestry. Aquatic plants occur among seed plants but these are adaptations of land plants to an aquatic environment. After fertilization the female cell, now called the ovospore, divides and part of it develops into the embryo (new sporophyte), which remains dormant for a time still protected by the ovule which has developed to become the seed. The seed is a characteristic feature of this group, which is therefore often referred to as the Seed-plants. The seed is set free from the parent plant and serves as the means of dissemination (see Flower; Pollination; Fruit, and Seed). The Spermatophyta fall into two groups, the Gymnosperms (g.) and Angiosperms (a.). The former are the more primitive group, appearing earlier in geological time and showing more resemblance in the course of their life-history to the Pteridophyta. A recently discovered fossil group, the Pteridophyta (see Pteridobryophyta), have characters intermediate between the Pteridophyta and the more primitive seed-plants.

In gymnosperms—so-called because the ovules (and seeds) are borne on an open sporophyll or carpel—the sporophylls and microsporophylls are not as a rule associated in the same shoot and are generally arranged in cone-like structures; one or two small prothallial cells are formed in the germination of the microspores; the male cells are in some older members of the group, though not in the gymnosperms of the ova, and usually occupy the site of the embryonic shoot, and are successively produced with a thallus, in the upper part of which are formed several rudimentary archegonia. The fertilized egg-cell (embryo-sac) forms a Blastosporangium (embryo-sac) which is usually composed of a number of individual cells, each of which has a single male cell, or more embryos develop, one only as a rule reaching maturity. The embryo consists of an axis bearing two or more cotyledons and ending below in a radicle; it lies in a generally copious food-storing tissue formed between the leaves and the female prothallus. The plant has a well-developed main root (tap-root) and a single or branched leafy stem which is provided with a means of secondary increase in thickness. The leaves are generally thick-skinned and last for several years.

The angiosperms, which are much the larger class, derive their name from the fact that the carpel or carpels form a closed chamber, the ovary, in which the ovules are developed—associated with this is the assumption of the ovule by the megasporangium, and the pollen grain is deposited. The sporophylls (stamens and carpels) are generally associated with other leaves, known as the perianth, to form a flower; these subsidiary leaves are protective and attractive to the pollinating agency (see Amphigamia; Pollination, and Flower). The male gametophyte is sometimes represented by a transitory prothallial cell; the two male cells are contained in a structure formed at the time of the development of the ovule by means of the pollen-tube. The female gametophyte is extremely reduced; there is a sexual apparatus of naked cells, one of which is the egg-cell which, after fusion with a male cell, divides to form a large number of cells and the nucleus of the egg-cell is formed as the result of the fusion of the second male cell with the so-called "definitive nucleus" of the embryo-sac (see Angiosperms). The embryo consists of a basis formed (Monokotyledon) or two (Dicotyledons) cotyledons, which remain enclosed and lying low in the embryo, in the course of development the cotyledons and ending below in a radicle. The seed is enclosed when ripe in the fruit, a development of the ovary as a result of fertilization of the egg-cell. (A. B. R.)

ANATOMY OF PLANTS

The term "Anatomy," originally employed in biological science to denote a description of the facts of structure revealed on cutting up an organism, whether with or without the aid of lenses for the purposes of magnification, is restricted in the present article, in accordance with a common modern use, to those facts of internal structure not concerned with the constitution of the individual cell, the structural unit of which the plant is composed.

An account of the structure of plants naturally begins with the cell which is the proximate unit of organic structure. The cell is essentially an individualized mass of protoplasm containing a differentiated protoplasmic body, called a nucleus. But all cells which are permanent tissue-elements of the plant-body possess, in addition, a more or less rigid limiting membrane or cell-wall, consisting primarily of cellulose or some allied substance. It is the cell-walls which connect the different cells of a tissue (see below), and it is upon their characters (thickness, sculpture and constitution) that the qualities of the tissue largely depend. In many cases, indeed, after the completion of the cell-wall (which is secreted by the living cell-body) the protoplasm dies, and a tissue in which this has occurred consists solely of the dead framework of cell-walls, enclosing in the cavities, originally occupied by the protoplasm, simply water or air. In such cases the characters of the adult tissue clearly depend solely upon the characters of the cell-walls, and it is usual in plant-anatomy to speak of the wall with its enclosed

Fig. 1.—Examples of the differentiation of the cells of plants.

A. Cell (individual) of the unicellular Green Alga Pleurocapsa, as an example of an undifferentiated autonomous assimilating cell. (a.) Cell protoplasm; (n.), nucleus; (ch.), chloroplast; (w.), cell-wall.

B. Plant of the primitive Siphonaceous Green Alga Protosiphon botryoides. The primitive cell sends colourless tubes (thallus, rh.) into the mud on which it grows. The subaerial part is tubular or ovoid, and contains the chloroplast (ch.). There are several nuclei.

C. Base of the multicellular filamentous Green Alga Chaetomorpha aerea. The basal cell has less chlorophyll than the others, and is expanded and fixed firmly to the rock on which the plant grows by the basal surface, rh. thus forming a rudimentary rhizoid.

D. Part of branched filamentous thallus of the unicellular Green Alga Oedogadium. (cr.), Green axis creeping on the surface of damp soil; (rh.), colourless rhizoids penetrating the soil; (ass. ax.), ascending axes of green cells.

E. Vertical section of frond of the complicated Siphonaceous Green Alga Halimeda. The substance of the frond is made up by a single much-branched tube, with interwoven branches. Cond. med., Longitudinally running comparatively colourless central (medullary) branches, which conduct food substances and support the (ass. cor.) green assimilating cortical branches, which are the ends of branches from the medulla and fit tightly together, forming the continuous surface of the plant.

F. Section through the surface tissue of the Brown Alga Cystillaria merteoides, showing the surface layer of assimilating cells densely packed with phaeoplasts. The layers below have progressively fewer of these, the central cells being quite colourless.

G. Section showing thick-walled cells of the cortex in a Brown Alga (Cladophora) (Cond. med.) enabling conduction to take place readily from one to another.

H. Two adjacent cells (leptoids) of a food-conducting strand in Fucus (a Brown seaweed). The wall between them is perforated, giving passage to coarse strands of protoplasm.

I. End of hydroid of the thalloid Liverwort Blyttia, showing the thick lignified wall penetrated by simple pits.
cavity as "the cell," and the contained protoplasm or other substances, if present, as *cell-contents*. This is in accordance with the original use of the term "cell," which was applied in the 17th century to the cavities of plant-tissues on the analogy of the cells of honeycomb. The use of the term to mean the individualized nucleated mass of living protoplasm, which, whether with or without a limiting membrane, primitively forms the proximate histological element of the body of every organism, dates from the second quarter of the 19th century. For a more detailed description of the cell see CYTOLOGY and the section on *Cytology of Plants* below. In all but the very simplest forms the plant-body is built up of a number of these cells, associated in more or less definite ways. In the higher (more complicated) plants the cells differ very much among themselves, and the body is composed of definite systems of these units, each system with its own characteristic structure, depending partly on the characters of the component cells and partly of the higher plants. The term *parenchyma* is applied to tissues whose cells are isodiametric or cylindrical in shape, *prosenchyma* tissues consisting of long narrow cells, with pointed ends.

We may now proceed to a systematic account of the anatomy of the different groups of plants, beginning with the simplest, and passing to the more complicated forms.

**Thallophyta.**—The simplest members of both the Algae and the Fungi (g.g.) (the two divisions of the Thallophyta, which is the lowest of the four great groups into which the plant-kingdom is divided) have their bodies each composed of a single cell. In the Algae such a cell consists essentially of: (1) a mass of protoplasm provided with (2) a nucleus and (3) an assimilating apparatus consisting of a coloured protoplasmic body, called a *chlamydospore*, the pigment of which in the pure green forms is chlorophyll, and which may then be called a *chloroplast*. The whole of these living structures are covered externally by the dead cell-membrane (fig. 1 A). It is from such a living and assimilating cell, performing as it does all the vital functions of a green plant, that, according to current theory, all the different cell-forms of a higher plant have been differentiated in the course of descent.

Among the Green Algae the differentiation of cells is comparatively slight. Many forms, even when multicellular, have all their cells identical in structure and function, and are often spoken of as "physiologically unicellular." The cells of red algae are commonly jointed end-to-end in simple or branched filaments. Such differentiation as exists in the higher types mainly takes two directions. In the fixed forms the cell or cells which attach the plant to the substratum often have a peculiar form, containing chlorophyll and serving as a rudimentary fixing organ or rhizoid (fig. 1 C). In certain types living on damp soil, the rhizoids penetrate the substratum, and in addition to fixing the plant absorb food substances (dissolved salts) from the substratum (fig. 1 B) and the second type of differentiation is that between supporting axis and assimilating appendages. The cells of the axis are commonly stouter and have much less chlorophyll than those of the appendages (Draparnaldia). This differentiation is paralleled with that between stem and leaf of the higher plants. In the group of the Siphonophora both these types of differentiation may exist in the single, long, branched, tube-like and multinucleate "cell" (coenocyte) which forms the plant-body. *Protoperophora* (fig. 1 A) is an example parallel with *Oedologadium*; Bryopsis, with *Draparnaldia*. In Caulerpa the initiation of a higher plant by the differentiation of fixing, supporting and assimilating organs (root, stem and leaf) from different branches of the simple single cell is strikingly complete. In the terrestrial family of Coniferopsida the whole cell become considerably interwoven one with another, so that a dense tissue-like structure is often produced. In this we get a further differentiation between the central tubes (branches of the stem) and the "radial" rays which direct the plant to its function as a whole, possess little or no chlorophyll, and have doubt to conduct food substances from one region to another, and the peripheral ones, which are directed perpendicularly to the surface of the body, conduct and, pushing among the abundant chlorophyll, and are the assimilating organs (fig. 1 E).

None of the existing Red Seaweedes (Rhodophyceae) has a unicellular body. The thallus in all cases consists of a branched filament of cells placed end-to-end, as in many of the Green Algae. Such a branch grows simply by the transverse division of its apical cell. The branches may be quite free or they may be united laterally to form a solid body of more or less firm and compact consistency. This differentiation is paralleled by a differentiation in the thallus giving off from every side a number of short sometimes unicellular branches, which together form a cortex round the central thread, the whole structure having a cylindrical form which only branches which have the shape of the thallus thread grows out beyond the general surface and forms in its turn a new central thread, from whose cells arise new short branches. Or the thallus may have a leaf-like form, the branches from the central thread which form the midrib growing out mainly in one plane and forming a splitting like the midrib of a leaf, its lateral similar to the thallus branch itself, but the branchlets themselves are packed with chlorophylls and form the chief assimilating tissue of the plant. In the bulky forms colourless branches frequently grow out from some of the cortical cells, pushing among the already-formed threads in a longitudinal direction, serve to strengthen the thallus by weaving its original threads together. The cells belonging to any given thread may be recognized at an early stage of growth, because each cell

**Fig. 10.**—Examples of the differentiation of the tissue of plants.

I. End of hydroid of the Moss *Minium*, showing particularly thin oblique end-wall. No pits.
J. Optical section of two adjacent lepidots of the Moss *Polytrichion juniperinum*. The lepidots are living and nucleated. They bulge in the neighbourhood of the very thin cross-wall. Note resemblance to *H* and *B*. L. Optical section of cell of parenchyma in the same moss. Embedded in the protoplasm are a number of starch grains. M. Part of elongated stereo of a Moss. Note thick walls and oblique slit-like pits with opposite inclination on the two sides of the cell seen in surface view. N. One side of the end of hydroid (tracheid) of a Pteridophyte (fern), with scalariform pits.
O. Optical section of two adjacent lepidots (sieve-tube segments) of Pteridophyte, with sieve plates (s. pl.) on oblique end-wall and side-walls.
P. Part of spiral hydroid (tracheid) of Phanerogam (Flowering Plant). Q. Three segments of a "pitted" vessel of Phanerogam.
R. Optical section of lepidot (sieve-tube segment) of Phanerogam, with two protein (coarse) cells s. pl., sieve-plate.
S. Optical section of part of thick-walled stereo of Phanerogam, with almost obliterated cavity and narrow slit-like oblique pits.
T. Part of vertical section through blade of typical leaf of Phanerogam, e.g. *Uropodopteris*, with (c) cuticle. (p) Assimilating (palisade) cells. s. pl. Assimilating (spongy) cells with large lacunae. i.e., Lower epidermis, with *st*. stomata.
U. Assimilating cell, with process (root-hair) from piliferous layer of root of Phanerogam.
V. Endodermal cell of Phanerogam, with suberized central band on radial and transverse walls.

on the method of association. Such a system is called a *tissue*-system, the word tissue being employed for any collection of cells with common structural, developmental, or functional characters to which it may be conveniently applied. The word is derived from the general resemblance of the texture of plant substance to that of a textile fabric, and dates from a period when the fundamental constitution of plant substance from individual cells was not yet discovered. It is convenient here to define the two chief types of cell-form which characterize tissues
is connected with its neighbours belonging to the same thread by two depressions or pits, one at each end. The common wall separating the pits of the two adjoining cells is pierced by strands of protoplasm. The whole structure, consisting of the two pits and the wall between, is known as a genetic cell. Other walls, however, do not belong to the same branch, are, however, formed at a later stage.

Many of the lower forms of Brown Seaweeds (Phæophyceæ) have a thallus consisting of single or tufted cells in a very high form: these possess a solid thallus, often of very large size, the plant-body no longer formed entirely of branched cell-threads, but consists of what is called a true parenchymatous tissue, i.e. a solid mass of cells, having no cell division in all directions of space. In the Laminariaceæ the tissue is more or less solid, and cells in the thallus are interwoven and form the assimilating tissue (fig. 1). In these brown types with bodies of considerable thickness (Laminariaceæ and Fucaceæ), there is, however, a further differentiation of the internal tissues. The cells of the external layer are specialized for the reception of light, and form a colourless, or nearly colourless, parenchymatous cortex, which acts as a food storage tissue (fig. 1, G), and surrounds a central medulla of elongated conducting cells. The latter are often swollen at the ends, and separate each cell segment from the end of the medulla, and cells in the tissue of this kind, and use of the various organs to which different Fungi are exposed. In many forms its hypae are particularly thick-walled, and may strikingly resemble the epidermis of a vascular plant. This is especially the case in the lichens (symbiotic organisms composed of a fungal mycelium in association with algal cells), which are usually exposed to very severe fluctuations in external conditions. The formation of a massive body naturally involves the localization of the absorptive region, and the function of absorption (which in the lichens is carried out by the whole of the vegetative part of the mycelium penetrating a solid or immersed in a liquid substratum) is subserved by the outgrowth of the layer of the surface-layer of that region into rhizoids, which, like those formed by Algae on soil, form the root-hairs of the higher plants. The internal tissue of the body of the solid higher Fungi, particularly the elongated stalks (stipes) of the fruticifactions of the Agarics, consists of hypae running in the longitudinal direction, which do not serve for the conduction of organic food substances, just as do the "trumpet-hyphae," similar in appearance, though not in origin, of the higher Brown Seaweeds. (In one genus (Lactarius) "milk-tubes," recalling the lactiferous tubes of many vascular plants, are formed.) These elongated hypae are frequently thick-walled, and in some cases form a central strand, which may serve to resist longitudinal pulling strains. This is particularly marked in certain lichens of shrubby habit.

The internal tissues, either consisting of obvious hypae or of pseudoparenchyma, may also serve as a storehouse of plant food substances.

Looking back over the progress of form and tissue-differentiation in the Thallophyta, we find that, starting from the simplest unicellular forms with no external differentiation of the body, we have a gradual increase in complexity of organization everywhere determined by the principles of the organic structure of all physiological labour and of the adaptation of the organism to the needs of its environment. In the first place there is a differentiation of fixing organs, which in forms living on a soft nutrient substratum penetrate it and become absorbing organs. Secondly, in the Algae, which build up their own food from inorganic materials, we have a differentiation of supporting axes from assimilating appendages, and as the body increases in size and becomes a solid mass of cells or interwoven threads, a corresponding differentiation of a superficial assimilative system from the deep-lying parts. In both Algae and Fungi the latter are primarily supporting and food-conducting, and in some bulky Brown Seaweeds, where assimilation is strongly localized, some of the deep cells are highly specialized for the latter function. In the higher forms a storage and a mechanically-strengthening system may also be developed, and in some aerial Fungi an external protective tissue. The "hypal" mode of growth, i.e. the formation of the thallus, whatever its external form, by branched, continuous or separte, coenocytic tubes (Phaeophaeæ and Ulotrichæ), is perhaps the most characteristic of the group. The exceptions being met with almost entirely among the higher Brown Seaweeds, in which is found parenchyma produced by the segmentation of an apical cell of the whole shoot, or by cell division in some other type of meristem.

Bryophyta.—The Bryophyta [including the Liverworts (Hepaticæ) and Mosses (Musci)], the first group of mainly terrestrial plants, exhibit considerably more advanced tissue differentiation, in response to the greater complexity in the conditions of life on land. In a general way this greater complexity may be said to consist (1) in the restriction of regular absorption of water to those parts of the plant-body embedded in the soil, (2) in the evaporation of water from the parts exposed to the air (transpiration). But these two principles do not find their full expression till we come in, the ascending series, to the Vascular Plants. In the Bryophytes water is still absorbed, not only from the soil but also largely from rain, dew, &c., through the general surface of the subaerial body (thallus), which in some groups runs through the leaves. The lowest Hepaticæ have an extremely simple vegetative structure, little more advanced than that found in some of the higher Green Algae and very much simpler than in the large Red and Brown Seaweeds. The plant-body (thallus) is always small and normally lives in very damp air, so that the demands of terrestrial life are at a minimum. It always consists of true parenchyma, and is entirely formed by the cutting off of segments from an apical cell.
PLANTS

A sufficient description of the thallus of the liverworts will be found in the article Bryophyta. We may note the universal occurrence on the lower surface of the thallus of fixing and absorbing rhizoids in accordance with the terrestrial tissue-differentiation, possessing a distinct assimilative system of cells, consisting of branched cell threads packed with chloroplasts and arising from the basal cells of large cavities in the upper part of the thallus, and in most species of liverworts, these are the archegonia or female reproductive structures; in others, there are one or more strands or bundles consisting of long thick-walled fiber-like (prosenchymatous) cells, pointed at the ends and running longitudinally through the thallus, which are arranged in spirals running the cells, and are often elongated in the direction of the spiral (fig. 1, 1).

These cells are not living in the adult state, though they sometimes contain a few chloroplasts. This is the ordinary thallus of the liverwort, with one or more strands, or bundles of rhizoids, and it forms the hydrothallus. The thallus of the liverworts is in the simplest forms simply a sponge-capsule with arrangements for the development, protection, and distribution of the spores. As such, it is a more usual thallus in the thalloid liverworts, or an outgrowth of organic food from the thallus of the mother plant (the gametophyte), richly chlorophyllous tissue with numerous interspersed spaces communicates with the exterior by stomata, strikingly similar to those of the vascular plants (see above). If the axis of such a sporophyte is emergent, the thallus is elongated into the soil to form a fixing and absorptive root, the whole structure would become a physiologically independent plant, exhibiting in many ways no less all respects the leading features of the sporophyte or plant; some of the liverworts have such a sporophyte, but most of the liverworts have a thallus, consisting of few to many cell threads, or bundles of fibers, and these are the thalloid liverworts (Acrogyneae), whose plant-body consists of a thin supporting stem bearing leaves. The latter are plates of green tissue one cell thick, while the stem consists of a unicellular layer. It has been shown that it consists of the stem bears numerous cell-filaments (rhizoids) which fix the plant to the substrate upon which it is growing.

In the Mosses the plant-body (gametophyte) is always separable into a rafts of green tissue and a supporting strand of cells. The thallus of the moss differs from the liverwort in the histology of the comparatively simple, but in many respects aberrant Bog-mosses (Sphagnumaeae), see Bryophyta.] The stems of the other mosses resemble one another in their main histological features. There is a special superficial or epidermal layer, usually thick, thin, flat, assimilating, and transpiring appendages (leaves). To the base of the stem are attached a number of branched cell threads (rhizoids) which ramify in the soil, fixing and absorbing the soil. The leaves are conjoined with the thallus, and are often present above the soil. The thallus of the liverwort is in the simplest forms simply a sponge-capsule with arrangements for the development, protection, and distribution of the spores. As such, it is a more usual thallus in the thalloid liverworts, or an outgrowth of organic food from the thallus of the mother plant (the gametophyte), richly chlorophyllous tissue with numerous interspersed spaces communicates with the exterior by stomata, strikingly similar to those of the vascular plants (see above). If the axis of such a sporophyte is emergent, the thallus is elongated into the soil to form a fixing and absorptive root, the whole structure would become a physiologically independent plant, exhibiting in many ways no less all respects the leading features of the sporophyte or plant; some of the liverworts have such a sporophyte, but most of the liverworts have a thallus, consisting of few to many cell threads, or bundles of fibers, and these are the thalloid liverworts (Acrogyneae), whose plant-body consists of a thin supporting stem bearing leaves. The latter are plates of green tissue one cell thick, while the stem consists of a unicellular layer. It has been shown that it consists of the stem bears numerous cell-filaments (rhizoids) which fix the plant to the substrate upon which it is growing.
undulata the central hydrom of the aerial stem is a loose tissue, its interstices being filled up with thin-walled, starfish parenchyma. In Dawsonia superba, a large New Zealand moss, the hydroms of the central cylinder of the aerial stem are mixed with thick-walled stergs forming a hydrom-stereom strand somewhat like that of the rhizome in other Polytrichaceae.

The central hydrom strand in the seta of the sporogonium of most mosses has already been alluded to. Besides this there is usually a living conducting tissue, sometimes differentiated as leptorhiz, forming a mantle round the hydrom, and bounded externally by a more or less well-differentiated endodermis, abutting on an irregularly cylindrical lacuna; the latter separates the central conducting cylinder from the cortex of the seta, which, like the cortex of the gametophyte stem, is usually differentiated into an outer thick-walled stereom and an inner starfish parenchyma. Frequently, also, a considerable differentiation of vegetative tissue occurs in the wall of the sporocapsule itself, and in some of the higher mosses, special assimilating and transpiring organs develop just below the capsule at the top of the seta, with a richly lacunar chlorophyllous parenchyma and stomata like those of the wall of the capsule in the Anthoceraceae liverworts. Thus the histological differentiation of the sporogonium of the higher mosses is one of considerable complexity; but there is here even less reason to suppose that these tissues have any homology (phylogenetic community of origin) with the similar ones met with in the higher plants.

The features of histological structure seen in the Bryophytic series are such as we should expect to be developed in response to the exigencies of increasing adaptation to terrestrial life on land, and of increasing size of the plant-body. In the liverworts we find the better developed rhizoids; in certain forms with a localized region of water-absorption the development of a primitive hydrom or water-conducting system; and in others with rather a massive type of thallus the differentiation of a special assimilative and transpiring system. In the more highly developed series, the mosses, this last division of labour takes the form of the differentiation of special assimilative organs, the leaves, commonly with a midrib containing elongated cells for the ready removal of the products of assimilation; and in the typical forms with a localized absorptive region, a well-developed hydrom in the axis of the plant, as well as similar hydrom strands in the leaf-mid ribs, are constantly met with. In higher forms the conducting strands of the leaves are continued downwards into the stem, and eventually come into connexion with the central hydrom cylinder, forming a complete cylindrical investment apparently distinct from the latter, and exhibiting a differentiation into hydrom, leptorhiz, and amyloph with which almost completely parallels that found among the true vascular plants. Similar differentiation, differing in some detail, takes place independently in the other generation, the sporogonium. The stereom of the thallus is found mainly in the outer cortex of the stem and in the midrills of the leaf.

Vascular Plants.—In the Vascular Plants (Pteridophytes, i.e. ferns, horse-tails, club mosses, &c., and Phanerogams or Flowering Plants) the main plant-body, that which we speak of in ordinary language as the "plant," is called the sporophyte because it bears the asexual reproductive cells or spores. The gametophyte, which bears the sexual organs, is either a free-living thallus corresponding in degree of differentiation with the lower liverworts, or it is a mass of cells which always remains enclosed in a spore and is parasitic upon the sporophyte.

The body of the sporophyte in the great majority of the vascular plants shows a considerable increase in complexity over that found in the gametophyte of Bryophytes. The principal new feature in the external conformation of the body is the acquisition of "true" roots, the nearest approach to which in the lower forms we saw in the "rhizome" of Polytrichaceae. The primary root is a downward prolongation of the primary axis of the plant. From this, as well as from various angles of the shoot system, other roots may originate. The root differs from the shoot in the characters of its surface tissues, in the absence of the green assimilative pigment chlorophyll, in the arrangement of its vascular system and in the mode of growth at the apex, all features which are in direct relation to its normally subterranean life and its fixative and absorptive functions. Within the limits of the sporophyte generation the Pteridophytes and Phanerogams also differ from the Bryophytes in possessing special assimilative and transpiring organs, the leaves, though these organs are developed, as we have seen, in the gametophyte of many liverworts and all the mosses. The leaves, again, have special histological features adapted to the performance of their special functions.

Alike in root, stem and leaf, we can trace a three-fold division of tissue systems, a division of which there are indications among the lower plants, and which is the expression of the fundamental conditions of the evolution of a bulky differentiated plant-body. From the primitive uniform mass of undifferentiated assimilating cells, which we may conceive of as the starting-point of differentiation, though such an undifferentiated body is only actually realized in the thallus of the lower Algae, there is, (1) on the one hand, a specialization of a surface layer regulating the immediate relations of the plant with its surroundings. In the typically submerged Algae and in submerged plants of every group this is the absorptive and the main assimilative layer, and may also by the production of mucilage be of use in the protection of the body in various ways. In the terrestrial plants it differs in the subterranean and subaerial parts, being in the former pre-eminently absorptive, and in the latter protective—provision at the same time being made for the gaseous interchange of oxygen and carbon dioxide necessary for respiration and feeding. This surface layer in the typically subaerial (2) body of the sporophyte in Pteridophytes and Phanerogams is known as the epidermis, though the name is restricted by some writers, on account of developmental differences, to the surface layer of the shoot of Angiosperms, and by others extended to the surface layer of the whole plant in both these groups. On the other hand, we have (3) an internal differentiation of conducting tissue, the main features of which as seen in the gametophyte of Bryophytes have already been fully described. In the Vascular Plants this tissue is collectively known as the vascular system. The remaining tissue of the plant-body, a tissue that we must regard phylogenetically as the remnant of the undifferentiated tissue of the primitive thallus, but which often undergoes further differentiation of its own, the better to fulfill its characteristically vital functions for the whole plant, is known, from its peripheral position in relation to the primitively central conducting tissue, as (3) the cortex. Besides absorption, assimilation, conduction and protection there is another very important function for which provision has to be made in any plant-body of considerable size, especially when raised into the air, that of support. Special tissues (sclerids) may be developed for this purpose in the cortex, or in immediate connexion with the conducting system, according to the varying needs of the particular type of plant-body. The important function of aeration, by which the inner living tissues of the bulky plant-body obtain the oxygen necessary for their respiration, is secured by the development of an extensive system of intercellular spaces communicating with the external air.

In relation to its characteristic function of protection, the epidermis, which, as above defined, consists of a single layer of cells and functionally shows a pronounced peculiar specialization, these serve not only to protect the plant against slight mechanical injury from without, and against the entry of smaller parasites, such as fungi and bacteria, but also and especially to prevent the evaporation of the plant body.

At intervals it is interrupted by pores (stomata) leading from the air outside to the system of intercellular spaces below. Each stoma is surrounded by a pair of peculiarly modified epidermal cells called guard-cells (fig. 1, T), which open and close the pores according to the needs of the plant. The structure of the stomata of the sporophyte of vascular plants is fundamentally the same as that of the stomata on the sporogonium of the true mosses and of the liverwort Anthoceros. Stomata are often situated at the bottom of pits in the surface of the leaf. This arrangement is a method of checking transpiration by creating a still atmosphere above the pore of the stoma, so that the water vapour collects in it and diminishes the further outflow of vapour. This type of structure, which is extremely various in its details, is found especially, as we should expect, in plants which have to economize their water
supply. The stomata serve for gaseous interchange between the plant and the surrounding air. The guard-cells contain chlorophyll, which is absent from typical epidermal cells, the latter acting as a tissue for water storage. Sometimes the epidermis is considered to be developed by tangential division of its cells, forming a many-layered water-tissue. This is found especially in plants which during certain hours of the day are unable to cover the water lost through transpiration by the supply coming from the roots. The water stored in such a time supplies the plant until the transpiration current prevents the injury which would result from their excessive depletion.

The epidermis of a very large number of species bears hairs of various kinds. The simplest type consists simply of modified outgrowths on the general level of the epidermis. Other hairs consist of a chain of cells; again, are branched in various ways; while yet others have the form of a flat plate of cells placed parallel to the leaf surface and often with a single thickened end. The latter may penetrate the epicuticle and absorb water; the former may contain, or they may simply contain air. A very common function of hairs is to diminish transpiration, by creating a still atmosphere between them, as in the case of the sunk stomata already mentioned. But hairs have a variety of other functions. They may, for instance, be glandular or stinging, as in the common stinging nettle, where the top of the hair is very brittle, easily breaking off when touched. The sharp, broken end penetrates the skin, and into the slight wound thus formed goes in water and air, which latter is absorbed by the hair end, the air is nearly saturated and water vapour is not. In one type they may take the form of specially-modified single epidermal cells or multicellular hairs without any direct connexion with the vascular system. The cells concerned, like all secreting organs, are usually well-protoplasmatic with large nuclei, and in addition, part of the cell-wall is modified as a filter. In a second type they are situated at the ends of tracheal strands and consist of groups of richly protoplasmatic cells belonging to the epidermis (as for instance in tomatoes, solanaceous, or commonest type in flowering plants); in this last case the cells in question are known as epithem. The epithem is penetrated by a network of fine intercellular spaces, which are normally filled with water and touch the surface of the hydathode or water-pot. Leaves in liquid form when transpiration is diminished so that the pressure in the water-channels of the plant has come to exceed a certain limit. They are widely distributed, but are particularly abundant in certain tropical climates where active root absorption goes on, and the air is nearly saturated with water vapour. In one type they may take the form of a so-called water-stoma, no doubt derived phylogenetically from an ordinary stoma, and enclosed by guard-cells which have nearly or entirely lost the power of movement. The stomata of these leaves are of the hydathode. The epithem is frequently surrounded by a sheath of cuticularized cells. In other cases the epithem may be absent altogether, the tracheal strand debouching directly on the lacunae of the cortex. The hydathode does not act as water-pot, but is merely a conduit of water-pot; the cavity is formed by the root firmly in the soil, and enabling the hair to absorb readily the thin films of water ordinarily surrounding the particles (fig. 1, U). The root-hair ends blindly and is an outgrowth from a surface cell, having no continuous wall. A very important form of hydathode is the Bryophyte. At the apex of a root, covering and protecting the delicate tissue of the growing point, is a special root-cap consisting of a number of layers of whose cells break down into mucilage towards the outer surface, thus facilitating the passage of the apex as it enlarges.

The cortex, as has been said, is in its origin the remains of the primitive assimilating tissue of the plant, after differentiation of the surface layer and the conducting system. It is, therefore, a fundamental layer of the plant, and its differentiation may be extremely varied, since in the complex bodies of the higher plants its functions are numerous. In all green plants which have a special protective epidermis, the cortex of the shoot has to perform the primitive fundamental function of carbon assimilation. In the leafy shoot this function is mainly localized in the cortical tissue of the leaves, known as mesophyll. Mesophyll, which is essentially a parenchymatous tissue containing chloroplasts, is penetrated by a system of intercellular spaces so that the surfaces of the assimilating cells are brought into contact with air to an enlarge extent, as possible, in order to facilitate gaseous interchange between the assimilating cells and the atmosphere. At the same time all the cells of the mesophyll are transpiring cells—i.e. the evaporation of water from the leaf goes on from them into the intercellular spaces, for the gases which thus pass between the cells of the mesophyll and the outside air of the stomata. A land plant has nearly always to protect itself against over-transpiration, and for this reason the stomata of the typical dorsivalent leaf (fig. 2, A), which has distinct upper and lower faces, is formed so that the lower face is under the water vapour that escapes from them, being lighter than air, cannot pass away from the surface of the leaf, but remains in contact with it and thus tends to check further transpiration. The stomata are in direct connexion with the atmospheric system of intercellular spaces which is found in the loosely arranged mesophyll (spongy tissue) on that side. This is the main transpiring tissue, and is protected from direct illumination and consequent too great evaporation. The main assimilating tissue, on the other hand, is under the upper epidermis, where it is well illuminated, and consists of oblong cells densely packed with chloroplasts and with their long axes perpendicular to the surface (palisade tissue). The intercellular spaces between these cells are thickened in the upper epidermis, and see that the mesophyll is this side so long and thus prevents the escape of the water-vapour from the palisade tissue into the intercellular spaces. Vascular bundles, which bear the leaf-muscles, are found in the mesophyll, and in the cortex, and in the xylem, in the xylem, in the xylem, in the xylem, in the xylem, in the xylem.
The innermost layer of the cortex, abutting on the central cylinder of the stem or on the bundles of the leaves, is called the phloem. This part of the plant, particularly in Pteridophytes, and universally in the root, the phloem is distinguished as an endodermis (see below). The innermost layer of the cortex does not constitute parenchyma of the rest of the cortex, though it is often distinguished by containing particularly abundant starch, in which case it is known as a starch sheath.

The characteristics common to the two highest groups of plants, the Pteridophytes and Phanerogams, is the possession of a double (hydrom-leptom) conducting system, such as we saw among the highest mosses, but in its further development, and with particular reference to the vascular system, it is probably indicating common descent throughout both these groups. This is confined to the sporophyte, which forms the leafy plant in these groups, and is known as the vascular system. Associated with it are other tissues, consisting of parenchyma, mainly starchy, and in the Phanerogams particularly, of special stoneware. The whole tissue is known as the stelar system (from the way in which in primitive forms it runs through the whole axis of the plant in the form of a cylinder). This is a similarity to the form of the pylogenetic connexion with that of the mosses. The origin of the Pteridophyta (p. 5.) is very obscure, but it may be regarded as certain that it is not to be sought among the mosses, which are an entirely different order of plants (cf. p. 26). Furthermore, both the hydrom and leptom of Pteridophytes have marked peculiarities to which no parallel is to be found among the Bryophytes. Hence we must conclude that the conducting system is a new acquisition of early character in the evolution. All the surviving forms, however, have a completely established double system with the specific characters alluded to, and since there is every reason to believe that the condition of the Pteridophyta is of older date than that of the primitive Pteridophytes, it is probable that the endodermal cells cannot be split apart to admit of the formation of intercellular spaces, and an air-tight sheath is formed round the cylinder. Such a vascular cylinder is called a hypostele, and the innermost layer of cells between the bundles of tracheids along the lines where the xylem touches the pericycle are spiral or annular, and are the xylem elements first formed when the xylem is developing. Each strand of spiral or annular first-formed tracheids is called a protoxylem strand, as distinct from the metaxylem or rest of the xylem, which consists of thick-walled tracheids, the pits of which are often scalariform. The thin-walled spiral or annular tracheae of the proteoxylem are the first-formed and shortest. They are followed later by the thickenings in the neighboring living parenchymatous cells of a growing organ. During the process the thin walls are stretched and the turns of the spiral become pulled apart without rupturing the wall wholly. The xylem, which was originally a layer of cells, were similarly stretched its continuously thickened walls would resist the stretching and eventually break. Hence such tracheae generally only laid down in organs of growth in length has ceased. The xylem cylinder is called a stele. The phloem or hypostele according to their structure contains one, two, or (rarely) three xylem films. When the protoxylem strands are situated at the periphery of the stele, abutting on the pericycle, as in all roots, and many of the more primitive Pteridophytes, the stele is said to be ephyllous. When there is a single protoxylem strand in the centre of the stele, or when, as is more commonly the case, there are several protoxylem strands situated at the internal limit of the xylem, the centre of the stem being occupied by the pericycle, this is the case in the stems of most Phanerogams and of some Pteridophytes. When the protoxylem have an intermediate position the stele is metaxylem (many seed plants). The xylem of Pteridophytes is not always arranged in a spiral, but in many cases at least the protoxylem is usually consisting of narrow sieve-tubes often with swollen walls, can be distinguished from metaxylem.

Evolution of the Stele in Pteridophytes. Vessels in Pteridophytes are entirely wanting. In a Pteridophyte is traced upwards from the primary root into the stem, the phloem becomes continuous round the xylem. At the same time the stele becomes more bulky, all its elements increasing in size and the youngest xylem is formed in the first leaf. This consists of a few xylem elements, a segment of phloem, pericycle, and usually an arc of endodermis, which closes round the bundle as it detaches itself from the stele. The xylem tissue thus formed towards it becomes bulkier, as do the successive leaf-bundles which leave it. In many Pteridophytes the solid hypostele is maintained throughout the axis. In others a central parenchyma of primitive phloem—similar to the xylem—is formed in the centre of the xylem. In most ferns internal phloem appears instead of a parenchymatous pit (p. 7). Sometimes this condition,
that of the amphiphloic haplostele, is maintained throughout the adult stem (Lindsaya). In the majority of ferns, at a higher level, after the stele has increased greatly in diameter, a large-celled true pith or medulla, resembling the cortex in its characters, and quite distinct from conjunctive, from which it is separated by an internal endodermis, appears in the centre. These successive new tissues, appearing in the centre of the stele, as the stem of a higher fern is traced upwards from its first-formed parts, are all in continuity with the respective corresponding external tissues at the point of origin of each leaf trace (see below). Where internal phloem is present this is separated from the internal endodermis by an endocycle or "internal pericycle," as it is sometimes called, and from the xylem by an internal mesocycle—these two layers, together with the outer mesocycle and pericycle, constituting the conjunctive tissue of the now hollow cylindrical stele. The conjunctive frequently forms a connected whole with bands of

starchy xylem-parenchyma, which, when the xylem is bulky, usually appear among the tracheids, the phloem also often being penetrated by similar bands of phloem-parenchyma.

In the other groups of Pteridophytes internal phloem is not found and an internal endodermis but rarely. The centre of the stele is however often occupied by a large-celled pith resembling the cortex in structure, the cortex and pith together being classed as ground tissue. To this type of stele having a "ground-tissue pith," whether with or without internal phloem, is given the name siphonostele to distinguish it from the solid haplostele characteristic of the root, the first-formed portion of the stem, and in the more primitive Pteridophytes, of the whole of the

mesocycle joining with the corresponding outer segments to form a nearly concentric structure. For this reason a stem in which the vascular system has this type of structure used to be spoken of as polyxylem, the term "stele" being transferred from the primary central cylinder of the axis and applied to the vascular strands just described. In this use the term loses, of course, its morphological value, and it is better to call such a segment of a broken-up stele a meristele, the whole siphonostele with overlapping leaf-gaps being called a dictyostele. The splitting up of the vascular tube into separate strands does not depend wholly upon the occurrence of leaf-gaps. In some forms other gaps (perforations) appear in the vascular tube placing the pith and cortex in communication.
In other cases the leaf-gaps are very broad and long, the meristems separating them being reduced to comparatively slender strands, while there is present in each gap a network of fine vascular threads, some of which run out to the leaf, while others cross-connections between these gaps. Such gaps are called polytectic and may consist of three or more meristems. Finally the cauline meristems themselves may be resolved into a number of fine threads. Such a structure may be spoken of as a dissected *dictionyte*. In certain primitive gymnosperms and many dicotyledons one or a few vascular strands are present which do not form part of the primary stele. These are known as *polycyclcs*. They usually run freely in the pith and join the primary tube in the neighbourhood of the leaf-gaps. A single file is then formed into a complete ring of xylem. The primary xylem of the first formed portion of the stem in all species of *Selaginella* which have been investigated possesses an exarch haplostele. The stelc of *Equisetum* is of a very peculiar type whose relations are not entirely clear. It is a single file of xylem running throughout the whole of the primary pith, forming a hollow pith. The protoxylem of each is a leaf-trace, while the metaxylem consisting of a right and a left portion forms a quite distinct cauline system. All the metaxylems join up to form a complete ring of xylem, which may be regarded as being surrounded by a common external endodermis; sometimes there is an internal endodermis in addition, separating the bundles from the pith; while in other cases each bundle possesses a separate sheath of external endodermis, and the internal endodermis to the bundles undergoes rather complex but definite changes. It is probable that this type of stelle is a modification of a primitive protostele, in which the main mass of stellary xylem has become much reduced and incidentally separated from the leaf-traces.

During recent years a number of fossil (Carboniferous and Permian) plants have been thoroughly investigated in the light of modern knowledge. They are known as *Steur Systeme* and the modern Gymnosperms (especially Cycads). Some of these genera have been used for *Polytopic Systemes*. We now know that all at least of the Cyacofilons bore seeds, of a type much more complex than that of most modern seed-plants, and in some cases approximating to the seeds of existing Cycads. In these the stellary members, excepting those formed from the primitive fern-protoxylem to the type characteristic of the Cycads which agrees in essentials in all the Spermmophytes. The main events in this transition appear to be these: (1) division of the vascular system of the protoxylem and root by pith, leading to the survival of a number of (mesarch) collateral bundles (see below) at the periphery of the stele; (2) passage from mesarch to endarch of these bundles correlated with a great increase in secondary thickening of the stele.

There is a general contemporaneous with the development of the fern-like and possessed a fern-like vascular strand; while in the later members, including the modern Cycads, the leaf bundles, remaining unaffected by secondary thickening, are mesarch, while those of the stems of the seed-plants. In the fossil series there are a number of others (Medulloseae and allied forms) which show numerous, very often complex, types of stellate structure, some cases polygonal, whose origin and relationship with the simpler and better known types is not yet fully understood. This may be termed *primary mediary bundles* (figs. 13, 23), the xylem of which is usually well-marked and enclosed in a central parenchymatous pith of certain families) and no internal endodermis. The xylem and phloem also, rarely form perfectly continuous layers as they do in a solenostelic fern. The vascular tissue is typically separable into distinct external bundles (figs. 13, 23), the xylem of which is usually well-marked and enclosed in a central parenchymatous pith. The inner layer of the cortex (phloem) forms a well-marked *endodermis*, or differ in other ways from the rest of the cortex. The outer cortex, and another layer, the pericycle, separates the phloem from the cortex. The inner layer of the cortex forms a well-marked *endodermis, or differ in other ways from the rest of the cortex. The outer cortex, and another layer, the pericycle, separates the phloem from the cortex.
Most of the collateral bundles of this siphonostelic type of siphonosteum are leaf-trace bundles, i.e., they can be traced upwards from any given point till they are found to pass out of the cylinder, travel through the cortex of the stem and enter a leaf. The remaining bundles (compensation) which go with the cylinder are such as have branched off from the leaf-traces, and will, after joining with others similarly given off, themselves form the traces of leaves situated at a higher level on the stem. Purely cauline vascular strands (i.e. confined to the stem) such as are found in the leaves of ferns are rare in the flowering plants. The leaf trace of any given leaf rarely consists of a single bundle only (unifacial); the number of bundles of any given trace is always odd; they may either be situated all together before they leave the stele or they may be distributed in intervals round the stele. The median bundles of the trace are typically the largest, and at any given level of the stem the bundles destined for the next leaf above are as a whole larger than the others which are destined to supply higher leaves. Leaf-trace gaps are formed in essentially the same way as in the ferns, but when in the case of a plurifascicular trace the bundles are distributed at intervals round the cylinder it is obvious that several gaps must be formed as the different bundles leave the stele. The gaps, are, however, often filled as they are formed by the development of external conjunctive tissue immediately above the points at which the bundles begin to bend out of the stele, so that sharply defined open gaps such as occur in fern-stems are but rarely met with in flowering plants. The constitution of the stele of a flowering plant is entirely from endarch collateral bundles, which are either themselves leaf-traces or will form leaf-traces alter junction with other similar bundles, is the great characteristic of the stele-stele of flowering plants. These collateral bundles are highly individualized, and their external conjunctive tissue is often arranged in relation to each bundle separately, the pericyclic fibres for instance, already referred to, being often confined to the bands of pericyclic tissue abutting on the phloem of each bundle, while in the cortex a pit frequently forms rays in the intervals between the adjacent bundles.

In some cases this individualization is carried further, the cortex and pith becoming continuous between the bundles which appear to be isolated, so that a collateral bundle is bedded in a general ground-tissue. Each bundle has its own investment corresponding with the stele, though the continuous cylinder no longer exists (species of Ranunculus). This condition is known as dictyostelic. In some gymnospermous stems (Nymphaeaceae) the number of bundles is greatly increased and they are scattered throughout the ground-tissue. A "peridesc" condition arises in such members of this order by the association of collateral bundles round common centres. A similar phenomenon is seen in two widely separated genera of flowering plants: Primula § Auricula and Gunnera (Halaognae).

The monocotyledon, one of the principal divisions of angiosperms, typically possess large monocot leaves with broad sheathing bases containing a very great number of bundles. This results in the number of bundles present at any given level of the stem being enormously increased. In monocotyledonous stems the bundles are scattered in a definite though not superficially obvious order through the conjunctive tissue of the stele, i.e., the outer diameter of the stele, the cortex being reduced to a very narrow layer, or disappearing altogether (fig. 3). The meshes of conjunctive tissue are developed as a large-scale "ground-tissue", and round each bundle there is a "peridesc". Monocotleaves are therefore, limited in the smaller stems, to such that the bundles occupy the whole of the ground-tissue, and there is no pit without a companion. In larger stems, the bundles are arranged in groups of two or three, and the pits are less common. In the larger stems the bundles are arranged in groups of two or three, and the pits are less common. In the larger stems the bundles are arranged in groups of two or three, and the pits are less common.

In the stems of many water-plants various stages of reduction of the vascular system, especially of the xylem, are met with, and very often this reduction leads to the formation of a compact stele in which the individuality of the separate bundles may be suppressed, so that a closed cylinder of xylem surrounds a pith. The phloem is generally unreduced, and there is normally a well marked endodermis (fig. 17).

In other cases the reduction goes much further, till the endodermis eventually comes to surround nothing but an intercellular channel formed in place of the stellate tissue.

The blade of a typical leaf of a vascular plant—essentially a thin plate of assimilating tissue—the vascular system takes the form of a number of separate, usually branching and anastomosing strands. These, with their associated stromes, form a kind of framework which is of great importance in supporting the mesophyll; but also, and chiefly, they provide a number of channels, penetrating every part of the leaf, along which water and dissolved salts are conveyed to, and elaborated food-substances from, the mesophyll cells. The bundle-system is of course continuous with that of the petiole and stem. The leaf-bundles are always collateral (the phloem being turned downwards and the xylem upwards), even in Ferns, where the petiolar strands are concentric, and they have the ordinary mesophyll and peridesc of the collateral bundle. The latter is often sclerified especially opposite the phloem, and to a less extent opposite the xylem, as in the stem. As a bundle is traced towards its end termination in the mesophyll the peridesc is split, and the sieve-tubes of the phloem are replaced by narrow elongated parenchyma cells, which soon die out, and the bundle ends with a strand of trabecules covered by the phloemterethy.

The structure of the stelo of the primary root as it is found in most Periplophites and many Phanerogams has already been described. The radial structure is characteristic of all root-stelae, which have in essential points a remarkably uniform structure throughout the vascular plants, a fact no doubt largely dependent on the very uniform conditions under which they live. While the stelo of the primary root in both Gymnosperms and Angiosperms is usually diarch or tetrarch, the large primary root-stelae of many adventitious roots are frequently polyarch, sometimes with a very large number of protoxylen. Such a stelo seldom has the centre filled with xylem, this being replaced by a large-celled pith, so that a siphonostelic structure is acquired (fig. 15). Sometimes, however, the centre of a bulky root-stelo has strands of metaxylen (to which may be added strands of meta- phloem) scattered through it, the interstices being filled with conjunctive. The conjunctive of a root-stelo possessing a pith is often sclerified between the pith and the pericycle. Sometimes all the parenchyma within the stelo undergoes this change. In the roots of some palms and orchids a "polystellic" structure obtains.

In certain families of Angiosperms a peculiar tissue, called laticeferous tissue or endodermis (fig. 17). This takes the form of long usually
PLANTS

Richly branched tubes which penetrate the other tissues of the plant mainly in a longitudinal direction. They possess a delicate layer of protoplasm, with numerous small nuclei lining the walls, while the interior of the tube (corresponding with the cell-contents) is composed of a viscid sub-membrane consisting of an emulsion of fine granules and drops of various substances suspended in a watery medium in which various other substances (sulphates, sugars, rubber-producers, tannins, alkaloids and various enzymes) are dissolved. Of these substances, caoutchouc, drops of resin and oil, proteid crystals and starch grains may be mentioned. Of this varied mixture of substances some are undoubtedly plastic (i.e., use in constructing new plant-tissue), others are apparently end-products of metabolism, in other words excreta, though they are not actually cast out from the plant-body. The relation of the laticiferous tissue to the assimilating cells under which they often end, and the fact that where this tissue is richly developed the conducting parenchyma of the bundles, and sometimes also the sieve-tubes, are poorly developed, as well as various other facts, point to the conclusion that the laticiferous system has an important function in conducting plastic substances, in addition to acting as an excretory reservoir. As a secondary function we may recognize, in certain cases, the power of closing wounds, which results from the rapid coagulation of coagulated latex in contact with the air. The use of certain plants as rubber-producers (notably Hevea brasiliensis, the Para rubber-tree) depends on this property. The trees are regularly tapped and the coagulated latex which exudes is collected and worked up into rubber. Opium is obtained from the latex of the opium poppy (Papaver somniferum), which contains the alkaloid morphine.

Laticiferous tissue is of two kinds: (1) laticiferous cells (coenocytes) (fig. 19) which branch but do not anastomose, and the apices of which keep pace in their growth with that of the other tissues of the plant (Apocynaceae, most Euphorbiaceae, &c.); (2) laticiferous vessels (fig. 20) which are formed from rows of meristematic cells, the walls separating the cells breaking down, so that a network of laticiferous tubes arises (Papaveraceae, Hevea, &c.). In some cases (Allium, Convolvulaceae, &c.) rows of cells with latex-like contents occur, but the walls separating the individual cells do not break down.

The body of a vascular plant is developed in the first place by repeated division of the fertilized egg and the growth of the products of division. The body thus formed is called the embryo, and this develops into the adult plant, not by continued growth of all its parts as in an animal, but by localization of the regions of cell-division and growth, such a localized region being called a growing-point. This localization takes place first at the two free ends of the primary axis, the descending part of which is the primary root, and the ascending primary shoot. Later, the axis branches by the formation of new growing-points, and in this way the complex system of axes forming the body of the plant obtains. In ordinary vascular plants the embryo, after developing up to a certain point, stops growing and rests, enclosed within the seed. It is only on "germination" of the latter that the development of the embryo into the free plant is begun. In the Pteridophytes, on the other hand, development from the egg is continuous.

The triple division of tissues is laid down in most cases at a very early period of development, in the flowering plants usually before the resting stage is reached. In many Pteridophytes the first leaf is formed very early, and the first vascular strand is developed at its base, usually becoming continuous with the cylinder of the root; the strand of the second leaf is formed in a similar way and runs down to join that of the first, so that the stem stele is formed by the joined bases of the leaf-traces. In other cases, however, a continuous primitive stele is developed, extending from the primary stem to the primary root, the leaf-traces arising later. This is correlated with the comparatively late formation and small development of the first leaves. The evidence scarcely admits of a decision as to which of these methods is to be regarded as primitive in descent. In the seed-forming plants (Phanerogams) one or more primary leaves (cotyledons) are already formed in the resting embryo. In cases where the development of the embryo is advanced at the resting period, traces run from the cotyledons and determine the symmetry of the stele of the primitive axis, the upper part of which often shows a stem-structure, in some respects at least, and is called the hypocotyledonary stem or hypocotyl, while the lower part is the primary root.

(After Haberlandt. From Vines' Text-Book of Botany, by permission.)

**Fig. 19**—A portion of a laticiferous coenocyte dissected out of the leaf of a Euphorbia (x10).

**Fig. 20**—Laticiferous Vessels from the cortex of the root Scorzonera hispanica, tangential section. A, Slightly magnified. B, A small portion highly magnified.

(radicile). In other cases the root structure of the stele continues up to the cotyledonary node, though the hypocotyl is still to be distinguished from the primary root by the character of its epidermis. On germination of the seed the radicle first grows out, increasing in size as a whole, and soon adding to its tissues by cell division at its apical growing-point. The hypocotyl usually elongates, by its cells increasing very greatly in the longitudinal direction both in number and size, so that the cotyledons are raised into the air as the first foliage-leaves. Further growth in length of the stem is thenceforward confined to the apical growing-point situated between the cotyledons. In other cases this growing-point becomes active at once, there being little or no elongation of the hypocotyl and the cotyledon or cotyledons remaining in the seed.

The structure of the growing-points or apical meristems varies much in different cases. In most Pteridophytes there is a single large apical cell at the end of each stem and root axis. This usually has the form of a tetrahedron, with its base occupying the surface of the body of the axis and its apex pointing towards the interior. In the stem, segments are successively cut off from the sides of the tetrahedron, and by their subsequent division the body of the stem is produced. In the root exactly the same thing occurs, but segments are cut off also from the base of the tetrahedron, and by the division of these the root-cap is formed (fig. 21). In both stem and root early walls separate the cortex from the stele. The epidermis in the stem and the surface layer of the root soon becomes differentiated from the underlying tissue. In some Pteridophytes segments of the apical cell is wedge-shaped, in others prismatic; in the latter case segments are cut off from the end of the prism turned towards the body of the stem. In other cases, again, a group of two or four prismatic cells takes the place of the apical cell. Segments are then cut off...
In most of the Phanerogams, instead of consisting of a single apical cell or a group of initials, is stratified—i.e. there is a differentiation of leaf-bundles, which typically begins at the base of the leaf and extends upwards into the leaf and downwards into the stem, is the first phenomenon in the development of vascular tissue, and is seen at a higher level than the formation of a stele. The latter is produced (except in cases of complete astylly where a cylinder is never formed) after a number of leaf-traces have appeared on different sides of the stem so as to form a circle as seen in transverse section, the spaces intervening between adjacent bundles becoming bridged by small-celled tissue closing the cylinder. In this fresh bundle may become differentiated and what remains of it becomes the rays of the fully-formed stele. Many cases exist which are intermediate between the two extreme types described. In these the stele becomes obvious in transverse section at about the same level as that at which the rays are developed. Where a large-celled pith is developed this often becomes obvious very early, and in some cases it appears to have separate initials situated below those of the hollow vascular cylinder. In some cases where there is apparently a well-defined pith at the apex, this is really the young pith, the distinction between the stelar and cortical initials, if it exists, being, as is often the case, impossible to make out. The young tissue of the stele, in a case of the modified siphonosteol characteristic of the dicotyledonous stem, differs from the surrounding pith and cortex in its narrow elongated cells, a difference produced by the stopping of transverse and the increased frequency of longitudinal divisions. This is especially the case in the young vascular bundles themselves (desma). The protoxylem and protophloem are developed from a few cells from the inner and outer margins respectively of the desmogen, the disorganized tissue left over giving rise to the segments of endoderm and pericycle capping the bundle. Differentiation of the xylem progresses outward, of the ray cells inward, but the two tissues never meet in the centre. Sometimes development stops altogether, and a layer of undifferentiated parenchyma (the mesoderm) is left between them; or it may continue indefinitely, the outer cells of the xylem appearing by their tangential displacement with the differentiation of tissue on each side. In this case the formation of the primary bundle passes straight over into the formation of secondary tissue by a cambium, and no line can be drawn between the two processes. The differentiation of the stele, which usually takes the form of a layer of pericyclic, and may extend to the endoderm and parts of the rays, takes place in most cases later than the formation of the primary vascular strand. In the very frequent cases where the bundles have considerable individuality, the fibrous pericycle can very clearly be seen originating from the same strand of tissue as the vascular elements themselves. In such cases it is part of the perisperm or sheath of elongated narrow-celled tissue surrounding the individual bundle.

The separation of layers in the apical meristem of the root is usually very much more obvious than in that of the stem. The outermost is the calyptrigen, which gives rise to the root-cap, and in Dicotyledons to the piliferous layer as well. The periblem, one cell thick, which appears to wind the apical region, is found in the stele of Monocotyledons; and the plerome, which is nearly always sharply separated from the periblem, gives rise to the vascular cylinder. In a few cases the boundaries of the different layers are not traceable. The protoxylem and phloem strands are developed alternately, just within the outer limit of the young cylinder. The differentiation of metaxylem follows according to the type of root-stele, and, finally, any stelar there may be is developed. Differentiation is very much more rapid—i.e. the tissues are completely formed much nearer to the apex, than is the case in the stem. This is owing to the elongating region (in which protoxylem and protophloem alone are differentiated) being very much shorter than in the stem. The root hairs grow out from the cells of the piliferous layer immediately behind the elongating region.

The branches of the stem arise by multiplication of the epidermis and cortex at a given spot, growing up to a protuberance at which an apex of meristem is established. The vascular system is connected with this in various ways with that of the parent axis by the differentiation of bundle-connexions across the cortex of the latter. This is known as exogenous branch-formation. The cells of the pericycle, usually opposite a protoxylem strand, divide tangentially and give rise to a new growing point. The new root thus laid down burrows through the cortex of the mother-root and emerges to the surface. This is perhaps the simplest case of that of the parent axis are made across the pericycle of the latter. Its cortex is never in connexion with the cortex of the parent, but with its pericycle. Adventitious roots, arising from stems, usually develop in the pericycle, but sometimes from other parts of the connexions.

In most of the existing Pteridophytes, in the Monocotyledons, and in annual plants among the Dicotyledons, there is no further growth of much structural importance in the tissues after differentiation from the primary meristems. But in nearly all perennial Dicotyledons, in all dicotyledons and gymnospermous trees and shrubs,
and in fossil Pteridophytes belonging to all the great groups, certain layers of cells remain meristematic among the permanent tissues, or after passing through a resting stage reacquire meristem-like properties, and give rise to secondary tissues. Such meristematic layers are called secondary meristems. There are two chief secondary meristems, the cambium and the phellogen.

The formation of secondary tissues is characteristic of most woody plants, to whatever class they belong. Every great group or phylum of vascular plants, when it has become dominant in the vegetation of the world, has produced members with the tree habit arising by the formation of a thick woody trunk, in most cases by the activity of a cambium.

The cambium in the typical case, which is by far the most frequent, continues the primary differentiation of xylem and phloem in the desmogen strand (see above), or arises in the resting mesoderm or mesocycle and adds new (secondary) xylem and phloem to the primary tissues. New tangential walls arise in the cells which are the seat of cambial activity, and an initial layer of cells is established which cuts off tissue mother-cells on the inside and outside, alternately contributing to the xylem and to the phloem. A tissue mother-cell of the xylem may, in the most advanced types of Dicotyledons, give rise to—(1) a tracheid; (2) a segment of a vessel; (3) a xylem-fibre; or (4) a vertical file of xylem-parenchyma cells.

In the last case the mother-cell divides by a horizontal wall, the mother-cell of the phloem may give rise to (1') a segment of a sieve-tube with its companion cell or cells; (2) a phloem fibre; (3) a single phloem-parenchyma (Cambium) cell, or a vertical file of short parenchyma cells. At certain points the cambium does not arise to xylem and phloem tissues, but cuts off cells on both sides which elongate radially and divide by horizontal walls. When a given initial cell of the cambium has once begun to produce cells of this sort it continues the process, so that a radial plate of cambium consisting of cells intermediate in structure between xylem and phloem. Such a cell-plate is called a mediulary ray.

It is essentially a living tissue, and serves to place the living cells of the secondary vascular tissues in communication. It conducts substances towards the extremities of the plant due to the fact that they are frequently full of starch, which they store in winter. They are accompanied by intercellular channels serving for the conduction of oxygen to, and carbon dioxide from, the living cells in the interior of the xylem. The vessels or tracheids of the xylem, being cut off from the cambium during the development of the ray, also cease to function during the period of respiration.

The xylem and phloem parenchyma consist of living cells, fundamentally similar in most respects to the medullary ray cells, which sometimes replace them altogether. The parenchyma is often divided into transverse bands, the layer of the phloem parenchyma is often found in strands associated with the tracheal elements. These strands are not isolated, but form a connected network through the wood, and the xylem parenchyma and cambium are then well represented in the medullary ray cells, with the tracheal elements by one-sided bordered pits—i.e., pits with a border on the tracheal element side, and simple on the parenchyma cell side. The fibres are frequently found in strands associated with the tracheal elements. These intermediate cells, like the ordinary parenchyma, frequently store starch, and the fibres themselves, though usually small, sometimes retain their protoplasm, and in that case may be used for starch accumulations. The vessels and tracheids are very various in size, shape and structure in different plants. They are nearly always aggregated in strands, which, like those of the parenchyma, are not isolated, but are connected with one another.

The xylem- and phloem-cells, which are intermediate between the fibres and the parenchyma, are also limited by thickened walls, and are reduced cavities, functioning as mechanical rather than as water-conducting elements. All transitions are found between such forms and typical tracheids. These fibres and tracheids are easily confused on superficial inspection, but the tracheids are much more closely related to the tracheary system than the parenchyma, and the boundary between them is not always distinct, so that the xylem-parenchyma layer is usually divided into a row of sieve-plates; plates also occur on the radial side-walls.

The tissue-elements just described are found only in the more complicated secondary vascular tissues of certain Dicotyledons. A few of these elements occur also in xylem and phloem formed from the simplest forms of xylem and phloem found in the primary vascular tissues both among Pteridophytes and Phanerogams to these highly differentiated types. In the simplest condition we have vessels, tracheides, sieve-plates, and sieve-tubes, respectively associated with parenchyma, which in the former case is usually amyloid, i.e., consists of starch-containing cells, and in the latter of proteid cells. This type is found in nearly all Pteridophytes and, so far as is known, in Cycadofilices, both in primary and secondary tissue. The xeromorphic

is furnished either by cortical cells or by the tracheal elements, in a few cases by fibres which are probably homologous with sieve-tubes. Among Gymnosperms the secondary xylem is similarly simple, consisting of tracheids which act as stomata as well as hydrom, and a little amyloid; while the phloem-parenchyma sometimes undergoes a differentiation, part being developed as amyloid, part as proteid cells immediately associated with the sieve-tube. In other cases the proteid cells of the secondary phloem do not form part of the phloem-parenchyma, but occupy the top and bottom cell-rows of the medullary rays, the middle rows consisting of ordinary starchy cells. The top and bottom rows of the xylem rays are often developed as irregularly-thickened radially-elongated tracheids, an adaptation for the radial conduction of water, and communicating with the ordinary tracheids of the secondary xylem by large bordered pits. The primary vascular tissues of Angiosperms are likewise nearly always simple, consisting merely of tracheae and sieve-tubes often associated with amyloid. A characteristic peculiarity, both in the primary and secondary tissue, is that the proteid cells of the phloem are here always sister-cells of the leptoids and are known as companion-cells. In the secondary tissues of Dicotyledons we may have, as already described, considerably more differentiation of the cells; all the varieties being referred, however, on the one hand to the tracheal or sieve-tube type, on the other to the parenchyma type. The main feature is the development of special vascular stomata and storage tissue. In some cases special secreting tissues, resin ducts, oil glands, laticiferous tissue, crystal sacs, etc., may be developed among the ordinary secondary vascular elements.

The limit of each year's increment of secondary wood, in those plants whose yearly activity is interrupted by a regular winter or dry season, is marked by a more or less distinct line, which is produced by the sharp contrast between the wood formed in the late summer of one year and that of the year next following. The abundance of water-conducting elements is in relation to the need for a large and rapid supply of water to the unfolding leaves in the spring and early summer. In Gymnosperms, where vessels and fibres are absent, the late summer wood is composed of radially narrow thick-walled vessels and tracheids, the wood forming in the late summer is always of a soft, or being that of the previous year's cambium, which is nearly always harder, owing to the deposit in them of special substances. Wood thus altered is known as heart-wood, or duramen, as distinguished from the young sap-wood, or alburnum, which, forming a new ring of wood each year, is softer and more easily worked, so that the trunk of the tree frequently becomes hollow, as is commonly the case in the willow. Heart-wood is first formed at very different epochs in the life of a tree, according to the species—e.g., after fifteen to twenty years in the oak, forty years in the ash, &c.
In many annual plants no cambium is formed at all, and the same is true of most perennial Pteridophytes and Monocotyledons.

When the vascular tissue of such plants is arranged in separate bundles these are said to be closed. The bundles of plants which form cambium, on the contrary, are open. In stems with open bundles the formation of cambium and secondary tissue may be confined to these, when it is said to be entirely fascicular. In that case either very little secondary tissue is formed, as in the gourds, some Ranunculaceae, &c., or a considerable amount may be produced (clematis, barberry, ivy). In the latter event the cells of the primary rays are either merely stretched radially, or they divide to keep pace with the growth of the bundles. If this division occurs by means of a limited, localized meristem connecting the cambial layers of adjacent bundles, an interfascicular is formed in addition to the fascicular cambium. The interfascicular cambium may form nothing but parenchymatous tissue, producing merely continuations of the primary rays. Such rays are usually broader and more conspicuous than the secondary rays formed within the wedges of wood opposite the primary bundles, and are distinguished as principal rays from these narrower subordinate or fascicular rays (fig. 24). This is the typical case in most trees where the primary bundles are close together. Where the primary bundles are further apart, so that the primary rays are wider, the interfascicular cambium may form several fairly broad (principal) secondary rays in continuation of certain radial bands of the primary ray, and between these, wedges of secondary xylem and phloem, or, finally, secondary xylem and phloem may be formed by the whole circumference of the cambium, fascicular and interfascicular alike, interrupted only by narrow secondary rays, which have no relation to the primary ones of these lianes. Sometimes the original cambial ring is broken into several arcs, each of which is completed into an independent circle, so that several independent secondary vascular cylinders are formed. The formation of additional cambial cylinders or fascicles is not always in the manner just described, but in some Gymnosperms. They may arise in the pericycle or endoderm of the stele, in the cortex of the stem, or in the parenchyma of the secondary xylem or phloem. The activity of the new cambium is distinguished as the formation of primary phloem and xylem. Each of these cambial processes, and the secondary cambia within them, and sometimes the activity of the successive cambia leaves simply results in the formation of concentric rings or arcs of secondary xylem and phloem. In other cases a more intricate arrangement of secondary tissue may be produced, quite impossible to interpret unless and until the stages of their development have been followed. Sometimes in lianes the whole stem breaks up into separate woody strata, often twisted like the strands of a rope, and running into one another at intervals. Another such cambium is a woody cambium, much like that of the trees, but in certain woods a secondary meristem is formed outside the primary bundles, and gives rise externally to a little secondary cortex, and internally to a secondary parenchyma in which are developed numerous zones of additional bundles, usually of concentric structure, with phloem surrounded by xylem.

The cambium in the root, which is found generally in those plants which possess a cambium in the stem, always begins in the conjunctive tissue internal to the primary phloems, and forms new (secondary) phloem in contact with the primary, and secondary xylem internally. In roots which thicken but slightly, whose cambium usually appears late, it is often developed as an increase of the external conjunctive tissues to proceed further, arcs of cambium are formed in the pericycle external to the primary xylems, and the two sets of cambial arcs join, forming a continuous, watery line on transverse section, with tissue, separate the primary xylem and phloem, and promote the primary xylems. Owing to the resistance offered by the hard first-formed secondary xylem, the bays are pushed outwards as growth proceeds, and the watery line becomes a circle. Opposite the primary xylem, the cambium either (a) forms a circle on both sides, making a broad, secondary (principal) ray, which interrupts the vascular ring and is divided at its inner extremity by the islet of primary xylem; or (b) forms secondary xylem and phloem in the ordinary way, completing the vascular ring; or (c) in the case, narrow, secondary rays are formed at intervals, just as in the stem. Thus the structure of an old thickened root approximates to that of an old thickened stem, and so far as the vascular tissue is concerned can be distinguished as distinct or separate vascular rays. Moreover, in the cambium and producing like the latter an external and an internal secondary tissue, this is the phellogen, Periderm, and the whole of the tissue it gives rise to is known as Periderm. The phellogen differs from the former in that its external product is the characteristic tissue known as cork. This consists typically of close-fitting layers of cells with completely suberized walls, intended to replace the epidermis as the external protective layer of the plant, when the latter, in consequence of further growth after its original formation, is broken off and cast off by the increase in thickness of the stem through the activity of the cambium. Cork is also formed similarly in the root after the latter has become through its primary stage as an absorptive organ, and its structure is becoming assimilated to that of the stem. The internal tissue formed by the phellogen is known as phelloderm, and consists usually of ordinary parenchyma. The phellogen may arise from the cortex, which is the outer protective layer of the stems—i.e. in the epidermis itself (rarely), in any layer of the cortex, or in the pericycle. Its most usual seat of origin in the stem is the external layer of the cortex immediately below the cambium. When this is the case, the phellogen gives off the outer bark, while the inner bark is formed by the cambium. The development of the phelloderm is dependent upon whether the phellogen has a superficial or a deep-seated origin. In the former case the formation of the phelloderm is a slow and gradual process; in the latter, considerable, since this tissue has to replace the lost outer cortex, as a protective and, in a certain sense, storage tissue.

Provision is made for gaseous interchange between the internal tissues and atmosphere, by the development of lenticels. These are special organs which interrupt the continuity of the impermeable layer of ordinary cork-cells. A lenticel is formed by the phellogen at a point where the latter is divided, actively giving rise to loose tissue of rounded cells which soon lose their contents, and between which air can pass to the tissues below (fig. 25). A lenticel appears to the naked eye as a rounded or elongated scar, often forming a distinct prominence on the surface of the organ. The lenticels of the stem are usually formed beneath stomata, whose function they take up after the...
PLANTS

stomata have been ruptured and cast off with the rest of the epidermis. Both cork and phelloderm may be differentiated in various ways. The former often has its cells lignified, and may consist of alternate layers of hard and soft cells. The latter may develop spongiosa, and may also be the seat of origin of new formations of various kinds—e.g., supplementary vascular bundles, anomalous cambial zones, &c. It is often enormously developed and forms a very important tissue in roots. In the stem of a tree the original phellogen is replaced by successive new phellogenous layers of deeper and deeper origin, each forming its own layer of cork. Eventually the new phellogen reaches the level of the secondary phloem, and are formed in the parenchyma of the latter, keeping pace in their inward march with the formation of fresh sapwood and the destruction of the former cortex, containing collenchyma.

The complex system of dead and dying tissues cut off by these successive periderms, together with the latter themselves—in fact, everything outside the innermost phellogen, constitutes what is often known botanically as the bark of the tree. Rhytidome is, however, a preferable term, as the word bark has long been established in popular usage to mean all the tissue that can easily be peeled off—i.e., everything down to the wood of the tree. The rough surface of the bark of many trees is due to the successive phellogenous layers not arising in regular concentric zones, but forming in areas which join with the earlier-formed areas, and thus causing the bark to come off in flakes or thick chunks. A layer of cork is regularly formed in most Phanerogams across the base of the petiole before leaf fall, so as to cover the wound caused by the separation of the leaf from the stem. Special "wound-cork" is also often formed round accidental injuries so as to prevent the retention of the tissues by the soilings in rain and the entrance of fungal spores and bacteria. A peculiar modification of periderm is formed by the cambium of the submerged organs (roots or stems) of many aquatic or marsh-loving plants. This may take various forms and may cover the whole of the organ or be localized in special regions; but its cells are always living and are separated by very large intercellular spaces containing air. This tissue is called aerenchym, and no doubt its function is to facilitate the respiration of the organs on which it is formed and to which the access of oxygen is difficult. In other cases, a similar formation of spongy but dead periderm tissue may occur for the same purpose in special patches, called pneumatodes, on the roots of certain trees living in marshy places, which rise above the soil in order to obtain air.

History and Bibliography.—The study of plant anatomy was begun in the middle of the seventeenth century as a direct result of the construction of microscopes, with which a clear view of the structure of plant tissues could be obtained. The Englishman Wedd and the Italian Malpighi almost simultaneously published illustrated works on the subject, in which they described, for the most part very accurately, what they saw with the new instruments. The subject was practically dormant for nearly a century and a half, largely owing to the dominance of classificatory botany under the influence of Linnaeus. It was revived by several German workers, among whom were Treviranus and Link, and later Moldenhawer, as well as by the Frenchmen Mirbel, at the beginning of the 19th century. The new work largely centred round a discussion of the nature and origin of vessels, conspicuous features in young plant tissues which thus acquired an importance in the contemporary literature out of proportion to their real significance in the construction of the vascular plant. The whole of the writings of this time are dominated by a preoccupation with the functions of the different tissues, in itself an excellent standpoint for investigation, but frequently leading in the case of these early investigators to one-sided and distorted views of the facts of structure. The pioneer of modern plant anatomy was Hugo von Mohl (1780), who carefully investigated and described the facts of anatomical structure without attempting to fit them into preconceived views of their meaning. He produced a solid body of accurately described facts which has formed the sure groundwork of subsequent advance. From Mohl down to the eighth decade of the century the study of anatomy was entirely in the hands of a group of German investigators, prominent among whom were several of the most eminent founders of modern scientific botany—such, for instance, as Nägeli, Satio and De Bary. To the first we owe the secure foundation of our knowledge of the structure and course of the vascular strands of the higher plants ("Uber den Bau und die Anordnung der Gefässbündel bei den Stamm und Wurzel der Phanerogamen," Beiträge zur wissenschaftlichen Botanik, Heft 1, Leipzig, 1850); to the second the establishment of the sound morphological doctrine of the central cylinder of the axis as the starting-point for the consideration of the general arrangement of the tissues, and the first clear distinction between primary and secondary tissues (Botanische Zeitung, 1861 and 1863); to the last the putting together of the facts of plant anatomy known up to the middle of the eighth decade of the century in that great encyclopaedia of plant anatomy, the Vergleichende Anatomie der Pflanzen, published in 2 volumes (1882-1889). In 1870-1871 Van Tieghem published his great work, "Sur la Racine," Ann. sci. nat. bot. (Paris). This was not only in itself an important contribution to plant anatomy, but served as the starting-point of a series of researches by Van Tieghem and his pupils, which has considerably advanced our knowledge of the facts of histology, and also culminated in the foundation of the doctrine of the stele (Van Tieghem and Douliot, "Sur la polysystème," Ann. sci nat. bot., 1887; Van Tieghem, Traité de botanique (2nd ed. Paris, 1889-1891). This has had a most important effect on the development in recent years of morphological anatomy.

In the progress of the last three decades, since the publication of De Bary's great work, five or six main lines of advance can be distinguished. First, the knowledge of the details of histology has of course advanced greatly in the direction through the ceaseless activity of very numerous mainly German workers, though no fundamentally new types of tissue have been discovered. Secondly, the histology of fossil plants, particularly woody plants of the Carboniferous period, has been placed on a sound basis, assimilated with general histological doctrine, and has considerably enlarged our conceptions of plant anatomy as a whole, though again without revealing any entirely new types of structure. This branch of the subject, founded by Corda, Göppert, Stenzel and others in Germany, was enormously advanced by Williamson's work on the Coal Measures plants, recorded in the magnificent series of memoirs, "Researches on the Organization of Fossil Plants of the Coal Measures" (Phil. Trans. Roy. Soc., vols. i.-xix., 1871-1883). The work of Solms Laubach in Germany, Renault and Bertrand in France, and in recent years, of Zeiller in France, and Scott, Seward and others in England, has advanced our knowledge of the anatomy of fossil plants in an important degree. While convincing us that the plants of past ages in the earth's history have lived under very similar conditions of life and made very much the same adaptive responses as their modern representatives, one of the main results of this line of work has been to reveal important data enabling us to fill various gaps in our morphological knowledge and to obtain a more complete picture of the evolution of tissues in the vascular plants. One of the most striking incidents in the progress has been the recognition within the last few years of the existence of an extinct group of plants lying on the borderland between Filicales and Gymnosperms, and known as the Cynodothecas, a group in which, curiously enough, the reproductive organs remained undiscovered for some time after the anatomy of the vegetative organs was sufficiently well known to afford clear evidence of their true affinities. Thirdly, we have to record very considerable
progress in our knowledge of distinctively morphological anatomy, i.e. the study of tissues from the standpoint of evolution. The Russian plant-anatomist, Russow, may be said to have founded the consideration of plant tissues from the point of view of descent (Vergleichende Untersuchungen über die Leitbündelkryptogamen, St. Petersburg, 1872; and Betrachtungen über Leitbündel und Grundgewebe, Dorpat, 1875). He was ably followed by Strasburger (Über den Bau und die Verrichtungen der Leitungsbahnen in den Pflanzen, Jena, 1891), Haberlandt and others. The explicit adoption of this point of view has had the effect of clearing up and rendering definite the older morphological doctrines, which for the most part had no fixed criterion by which they could be tested.

Since about 1895 this branch has been most actively pursued in England, where the work of Boodle and of Gwynne-Vaughan (especially on Ferns) has been the most important, leading to a coherent theory of the evolution of the vascular system in these plants (Tansley, Evolution of the Filicinæan System, Cambridge, 1908); and in America, where Jeffrey has published important papers on the morphology of the vascular tissues of the various groups of Pteridophytes and Phanerogams and has sought to express his conclusions in a general morphological theory with appropriate terminology. As a result of this activity Van Tieghem's so-called "Stellar theory" has been revised and modified in the light of more extended and detailed anatomical and developmental knowledge. Schoute's Die Stelar-Theorie (Gröningen, 1902), gives an important critical account of this subject.

Fourthly, attention must be called to the great development of what is called "Systematic Anatomy," i.e. the study of the anatomical features characteristic of the smaller groups of flowering plants, i.e. the orders, families, genera and species. Radlkofler (1893) was the first to call attention to the great importance of this method in systematic botany, as providing fresh characters on which to base a natural classification. Solereder's great work, Systematische Anatomie der Dicotylenorden (Stuttgart, 1898-1908; Eng. trans., Systematic Anatomy of Dicotyledons, Oxford, 1908), brings together so many of the facts as are at present known in an orderly arrangement. Theoretically this branch of the subject should connect with and form the completion of "morphological anatomy," but the field has not yet been sufficiently explored to allow of the necessary synthesis. The true relation of "systematic" to "ecological" anatomy (see below) also awaits proper elucidation.

Fifthly, we have to record the foundation of the modern study of "physiological anatomy" (i.e. the study of the specific functions of the various tissues) by Schwendener (Das mechanische Prinzip im Bau der Monocellden, 1874, and other works), followed by numerous pupils and others, among whom Haberlandt (Physiologische Pflanzen-Anatomie, Leipzig, 1st ed., 1884, 4th ed., 1909, and other works) is pre-eminent. The pursuit of this study has not only thrown valuable light on the economy of the plant as a whole, but forms an indispensable condition of the advance of morphological anatomy. A great deal of work still remains to be done in this department, which at the present time affords one of the most promising fields of anatomical investigation.

Finally we may mention "ecological anatomy," i.e. the study of anatomical features directly related to the habitat. A very considerable body of knowledge relating to this subject already exists, but further work on experimental lines is urgently required to enable us to understand the actual economy of plants growing under different conditions of life and the true relations of the fundamental anatomical characters which form the subject matter of "systematic anatomy" to those which vary according to the conditions in which the individual plant is placed. On these lines the future of anatomical study presents almost inexhaustible possibilities.

(A. G. T.)

PHYSIOLOGY OF PLANTS

The so-called vegetable physiology of a generation ago was in the main the study of the latter being followed by many more observers, and from its relative degree of advancement being the more capable of rapid development. It was fully recognized by its followers that the dominating influence in the structure and working of the body was the protoplasm, and the division of labour which it exhibited, with the accompanying or resulting differentiation into various tissues, was the special subject of investigation. Many who followed the study of vegetable structure did not at that time give an equal prominence to this view. The early historical researches of botanists led them to the recognition of the vegetable cell, and the leading writers in the middle of the 19th century pointed out the probable identity of Von Mohl's "protoplast" with the "sarcod" of zoologists. They laid great stress on the nitrogenous nature of protoplasm, and noted that it preceded the formation of the cell-membrane. But by the ordinary student of thirty years later their work was to some extent overlooked, and the cell-wall assumed a prominence to which it was not entitled. The study of the differentiation of protoplasm was at that time seldom undertaken, and no particular attention was paid either to fixing it, or to providing methods to be accurately applied to it, or to studying the action of chemical reagents upon it. It is only comparatively recently that the methods of histological investigation used by animal physiologists have been carefully and systematically applied to the study of the vegetable organisms. They have, however, been attended with wonderful results, and have revolutionized the whole study of vegetable structure. They have emphasized the statements of Von Mohl, Cohn, and other writers alluded to, that the protoplasm is here also the dominant factor of the body, and that all the peculiarities of the cell-wall can only be interpreted in the light of the needs of the living substance.

The Nature of the Organization of the Plant, and the Relations of the Cell-Membrane and the Protoplast.—This view of the structure of the plant and this method of investigation lead us to a greatly modified conception of its organization, and afford more completely an explanation of the peculiarities of form found in the vegetable kingdom.

The study of simple organisms, many of which consist of nothing but a little mass of protoplasm, exhibiting a very rudimentary degree of differentiation, so far as our methods enable us to determine any at all, shows that the duties of existence can be discharged in the absence of any cell-wall. Those organisms which possess the latter are a little higher in the scale of life than those which remain unclothed by it, but a comparison of the behaviour of the two quickly enables us to say that the membrane is of but secondary importance, and that for those which possess it, it is nothing more than a protective covering for the living substance. Its physical properties, permeability by water, extensibility and elasticity, receive their interpretation in the needs of the latter. We come, accordingly, to regard it as practically an exoskeleton, and its functions as distinctly subordinate to those of the protoplasm which it clothes. If we pass a little higher up the scale of life we meet with forms consisting of two or more cells, each of which contains a similar minute mass of living substance. A study of them shows that each is practically independent of the others; in fact, the connexion between them is so slight that they can separate and each become free without the slightest disadvantage to another. So long as they are connected together mechanically they have apparently the power of influencing one another in various ways, and of passing liquid or gaseous substances to each other without the cell-wall. These are the tissues which are, in fact, a colony or association of the protoplasmic units, though each unit retains its independence. When we pass, again, from these to examine more bulky, and consequently more complex, plants, we find that the differences which can be observed between them and the simple lowly forms are capable of being referred to the increased number of the protoplasmic units and the consequent enlarged bulk of the mass or colony. Every plant is thus found to be composed of a number of these protoplasmic units, or, as they may preferably be termed,
protoplasts, all of which are at first exactly alike in appearance and in properties. This is evident in the case of such plants as have a body consisting of filaments or plates of cells, and is little less conspicuous in those whose mass is but small though the cells are evidently capable of computation in three dimensions. It does not at first appear to be the same with the bulkerier plants, such as the ordinary green herbs, shrubs or trees, but a study of their earlier development indicates that they do not at the outset differ in any way from the simple undifferentiated forms. Each commences its existence as a simple naked protoplast, in the embryo-sac or the archegonium, as the case may be. After the curious fusion with another similar protoplast, which constitutes what we call fertilization, the next stage in complexity already noted may be observed, the protoplasm becoming clothed by a cell-membrane. Very soon the single cell gives rise to a chain of cells, and this in turn to a cell mass, the individual units of which are at first quite uniform. With increase of number, however, and consequently enlargement of bulk in the colony, differentiation becomes compulsory. The requirements of the several protoplasts must be met by supplies from without, and, as many of them are deep seated, varieties of need arise, so that various members of the colony are set apart for special duties, masses of them being devoted to the discharge of one function, others to that of another, and so on. Such limitations of the powers and properties of the individuals have for their object the well-being of the community of which those individuals are constituents.

**Physiological and Morphological Differentiation.**—The first indication of this differentiation in the vegetative body of the plant can be seen not only in the terrestial green plants which have been particularly referred to, but also in the bulkerier seaweeds. It is an extension of the first differentiation which was observable in the simple protoplasts first discussed, the formation, that is, of a protective covering. Fucus and its allies, which form conspicuous members of the larger Algae, have their external cells much smaller, more closely put together, and generally much denser than the rest of their tissue. In the lowly as well as the higher green plants we have evidence of specialization of the external protoplasts for the same purpose, which takes various shapes and shows different degrees of completeness, culminating in the elaborate barks which clothe our forest trees.

The second prominent differentiation which presents itself takes the form of a provision to supply the living substance with water. This is a primal necessity of the protoplast, and every cell gives evidence of its need by adopting one of the various ways in which the water supply which differentiation can be found to exist in the protoplasm of the simple unicellular organism shows the importance of an adequate water-supply, and indeed, the dependence of life upon it. The naked cells which have been alluded to live in water, and call therefore for no differentiation in connexion with this necessity; but those which are surrounded by a cell-wall always develop within themselves a vacuole or cavity which occupies the greater part of their interior, and the hydrostatic pressure of whose contents keeps the protoplasm in contact with the membrane, setting up a condition of turgidity.

The need for a constant supply of water is partly based upon the constitution of protoplasm, so far as we know it. The apparently structureless substance is saturated with it; and if once a cell is completely dried, even at a low temperature, in the enormous majority of cases its life is gone and the restoration of water fails to enable it to recover. Besides this intimate relationship, however, we can point to other features of the necessity for a constantly renewed water supply. The protoplasm derives its food from substances in solution in the water; the various waste products which are incident to its life are excreted into it, and so removed from the sphere of its activity. The raw materials from which the food is constructed are absorbed from the exterior in solution in water, and the latter is the medium through which the gaseous constituents necessary for life reach the protoplasm. Moreover, growth is essentially dependent upon water-supply. There is little wonder, then, that in a colony of protoplasts such as constitute a large plant a considerable degree of differentiation is evident, bearing upon the question of water supply. Certain cells of the exterior are set apart for absorption of water from the soil, this being the source from which supplies are derived. Others are devoted to the work of carrying it to the protoplasts situated in the interior and at the extremities of the plant, a conducting system of considerable complexity being the result.

Other collections of cells are in many cases set apart for giving rigidity and strength to the mass of the plant. It is evident that as the latter increases in bulk, more and more attention must be paid to the dangers of uprooting by winds and storms. Various mechanisms have been adopted in different cases, some connected with the subterranean and others with the sub-aerial portions of the plant. Another kind of differentiation in such a cell-mass as we are dealing with is the setting apart of particular groups of cells for various metabolic purposes. We have the formation of numerous mechanisms which have arisen in connexion with the question of food supply, which may not only involve particular cells, but also lead to differentiation in the protoplasm of those cells, as in the development of the chloroplasts of the leaves and other green parts.

The inter-relations of the members of a large colony of protoplasts such as constitute a tree, demand much adjustment. Relations with the exterior are continually changing, and the needs of different regions of the interior are continually varying, from time to time. Two features which are essentially protoplasmic assume a great importance when we consider these relations. They are the power of receiving impressions or stimuli from the exterior, and of communicating with each other, with the view of co-ordinating a suitable response. We have nothing structural which corresponds to the former of these. In this matter, differentiation has proceeded very differently in animals and plants respectively, no nerves or sense organs being structurally recognizable. Communication between the various protoplasts of the colony is, however, carried on by means of fine protoplasmic threads, which are continuous through the cell-walls.

All the peculiarities of structure which we encounter consequently support the view with which we started, that the protoplasm of the plant is the dominant factor in vegetable structure, and that there needs be but one subject of physiology, which must embrace the behaviour of protoplasm wherever found. There can be no doubt that there is no fundamental difference between the living substance of animals and plants, for many protoplasts exist which are characteristic of either kingdom. Free-swimming organisms without cell-membranes exist in both, and from them series of forms can be traced in both directions. Cellulose, the material of which vegetable cell-walls are almost universally composed, at any rate in their early condition, is known to occur, though only seldom, among animal organisms. Such forms as Volvox and the group of Myxomycetes have been continually referred to both kingdoms, and their true systematic position is still a subject of controversy. All physiology, consequently, must be based upon the identity of the protoplasm of all living beings.

This method of study has to a large extent modified our ideas of the relative importance of the parts of such an organism as a large tree. The interest with which we regard the latter no longer turns upon the details of the structure of its trunk, limbs and roots, to which the living substance of the more superficial parts was subordinate. Instead of regarding these as only ministering to the construction of the bulky portions, the living protoplasts take the first place as the essential portion of the tree, and all the other features are important mainly as ministering to their individual well-being and to their multiplication. The latter feature is the growth of the tree, the well-being of the protoplasts is its life and health. The interest passes from the bulky dense interior, with the elaborate features of its cell-walls, to the superficial parts, where its life is in evidence. We see herein the reason for the great subdivision of the body, with its
finely cut twigs and their ultimate expansions, the leaves, and we recognize that this subdivision is only an expression of the need to place the living substance in direct relationship with the environment. The formation and gradually increasing thickness of its bark are explained by the continually increasing need of adequate protection to the living cortex, under the strain of the increasing framework which the enormous multiplication of its living protoplasts demands, and the development of which leads to continual rupture of the exterior. The increasing development of the wood as the tree grows older is largely due to the demands for the conduction of water and mineral matters dissolved in it, which are made by the increased number of leaves which from year to year it bears, and which must each be put into communication with the central mass by the formation of new vascular bundles. Similar considerations apply to the peculiar features of the root-system. All these points of structure can only be correctly interpreted after a consideration of the needs of the individual protoplasts, and of the large colony of which they are members.

**Gaseous Interchanges and their Mechanism.**—Another feature of the construction of the plant has in recent years come into greater prominence than was formerly the case. The organism is largely dependent for its vital processes upon gaseous interchanges. It must receive a large constituent of what ultimately becomes its food from the air which surrounds it, and it must also take in from the same source the oxygen of its respiratory processes. On the other hand, the aerial environment presents considerable danger to the young and tender parts, where the protoplasts are most exposed to extremes of heat, cold, wet, &c. These must in some way be harmonized. No doubt the primary object of the cell-wall of even the humblest protoplast is protection, and this too is the meaning of the coarser tegumentary structures of a bulkier plant. These vary considerably in completeness with its age: in its younger parts the outer cells wall undergoes the change known as cuticulization, the material being changed both in chemical composition and in physical properties. The corky layers which take so prominent a share in the formation of the bark are similarly modified and subserve the same purpose. But these protective layers are in the main impermeable by gases and by either liquid or vapour, and prevent the access of either to the protoplasts which need them. Investigations carried out by Blackman, and by Brown and Escombe, have shown clearly that the view put forward by Boussingault, that such absorption of gases takes place through the cuticular covering of the younger parts of the plant, is erroneous and can no longer be supported. The difficulty is solved by the provision of a complete system of minute intercellular spaces which form a continuous series of delicate canals between the cells, extending throughout the whole substance of the plant. Every protoplast, except in the very young regions, has part of its surface abutting on these, so that its wall is accessible to the gases necessary for its vital processes. There is no need for cuticulization here, as the external dangers on influence do not reach the interior, and the processes of absorption which Boussingault attributed to the external cuticularized cells can take place freely through the delicate cell-walls of the interior, saturated as these are with water. This system of channels is in communication with the outer atmosphere through numerous small apertures, known as stomata, which are abundant upon the leaves and young twigs, and gaseous interchange between the plant and the air is by their assistance rendered constant and safe. This system of intercellular spaces, extending throughout the plant, constitutes a reservoir, charged with an atmosphere of air supplied to it through the cuticular covering of the external air, its gaseous constituents varying from time to time and from place to place, in consequence of the interchanges between itself and the protoplasts. It constitutes practically the exterior environment of the protoplasts, though it is ramifying through the interior of the plant.

The importance of this provision in the case of aquatic vascular plants of sturdy bulk is even greater than in that of terrestrial organisms, as their environment offers considerable obstacles to the renewal of the air in their interior. They are without stomata on their submerged portions, and the entry of gases can only take place by diffusion from the water through their external cells, which are not cuticularized. Those which are only partially submerged bear stomata on their exposed portions, so that their environment approximates towards that of a terrestrial plant, but the communication even in their case is much less easy and complete, so that they need a much larger reservoir of air in their interior. This is secured by the development of much larger intercellular spaces, amounting to lacunae or passages of very considerable size, which are found ramifying in different ways in their interior.

**Transpiration.**—In the case of terrestrial plants, the continual renewal of the water contained in the vacuoles of the protoplasts demands a copious and continuous evaporation. This serves a double purpose, bringing up from the soil continually a supply of the soluble mineral matters necessary for their metabolic processes, which only enter the plant in solutions of extreme dilution, and at the same time keeping the plant cool by the process of evaporation. The latter function has been found to be of extreme importance in the case of plants exposed to the direct access of the sun's rays, the heat of which would rapidly cause the death of the protoplasts were it not employed in the evaporation of the water. Brown and Escombe have shown that the amount of solar energy taken up by a green leaf may often be fifty times as much as it can utilize in the constructive processes of which it is the seat. If the heat were allowed to accumulate in the leaf unchecked, they have computed that its temperature would rise during bright sunshine at the rate of more than 12°C. per minute, with of course very rapidly fatal results. What is not used in the constructive processes is employed in the evaporation of the water, the leaf being thus kept cool. Whether the leaf is brightly or only moderately illuminated, the same relative proportions of the total energy absorbed are devoted to the purposes of composition and construction respectively. This large evaporation, which constitutes the so-called transpiration of plants, takes place not into the external air but into this same intercellular space system, being possible only through the delicate cell-walls upon which it abuts, as the external coating, whether bark, cork or cuticle, is impermeable by watery vapour. The latter ultimately reaches the external air by diffusion through the stomata, whose dimensions vary in proportion as the amount of water in the epidermal cells becomes greater or less.

**Mechanism and Function of Stomata.**—It is not quite exact to speak of either the gaseous interchanges or the transpiration as taking place through the stomata. The entry of gases into, and exit from, the cells, as well as the actual exhalation of watery vapour from the latter, take place in the intercellular space system of which the stomata are the outlets. The opening and closing of the stomata is the result of variation in the turgidity of their guard cells, which is immediately affected by the condition of turgidity of the cells of the epidermis contiguous to them. The amount of watery vapour in the air passing through a stoma has no effect upon it, as the surfaces of the guard cells abutting on the air chamber are strongly cuticularized, and therefore impermeable. The only way in which their turgidity is modified is by the entry of water into them from the contiguous cells of the general epidermis and its subsequent withdrawal through the same channel. This opening and closing of the stomata must be looked upon as having a direct bearing only on the emission of watery vapour. There is a distinct advantage in the regulation of this escape, and the mechanism is directly connected with the greater or smaller quantity of water in the plant, and especially in its epidermal cells. This power of varying the area of the apertures by which gases enter the internal reservoirs is not advantageous to the gaseous interchanges—indeed it may be directly the reverse. It may lead to an incipient asphyxiation, as the supply of oxygen may be greatly interfered with and the escape of carbon dioxide may be almost stopped. It may at other times lead to great difficulties in the supply of the gaseous constituents which are used in the
manufacture of food. The importance of transpiration, is, however, so great, that these risks must be run.

**The Ascent of Water in Trees.**—The supply of water to the peripheral protoplasts of a tree is consequently of the first importance. The means by which such a supply is ensured are by no means clearly understood, but many agencies are probably at work. The natural source of the water is in all cases the soil, and few plants normally obtain any from elsewhere. The water of the soil, which in well-drained soil is met with in the form of delicate films surrounding the particles of solid matter, is absorbed into the plant by the delicate hairs borne by the young roots, the entry being effected by a process of modified osmosis. Multitudes of such hairs on the branches of the roots cause the entry of great quantities of water, which by a subsequent similar osmotic action accumulates in the cortex of the roots. The great turgidity which is thus caused exerts a considerable hydrostatic pressure on the stele of the root, the vessels of the wood of which are sometimes filled with water, but at other times contain air, and this often under a pressure less than the ordinary atmospheric pressure. This pressure of the turgid cortex on the central stele is known as root pressure, and is of very considerable amount. This pressure leads to the filling of the vessels of the wood of both root and stem in the early part of the year, before the leaves have expanded, and gives rise to the exudation of fluid known as bleeding when young stems are cut in early spring.

Root pressure is one of the forces co-operating in the forcing of the water upwards. The evaporation which is associated with transpiration is no doubt another, but by themselves they are insufficient to explain the process of lifting water to the tops of tall trees. There is at present also a want of agreement among botanists as to the path which the water takes in the structural elements of the tree, two views being held. The older is that the water travels in the woody cell-walls of the vascular bundles, mainly under the action of the forces of root pressure and transpiration, and that the cavities of the vessels contain only air. The other is that the vessels are not empty, but that the water travels in their cavities, which contain columns of water in the course of which are large bubbles of air. On this view the water travels upwards under the influence of variations of pressure and tension in the vessels. These forces however fail to furnish a complete explanation of the ascent of the current, and others have been thought to supplement them, which have more or less weight. Westermayer and Godlewski put forward the view that the living cells of the medullary rays of the wood, by a species of osmosis, act as a kind of pumping apparatus, by the aid of which the water is lifted to the top of the tree, a series of pumping-stations being formed. Though this at first met with some acceptance, Strasburger showed that the action goes on in great lengths of stem, the cells of which have been killed by poison or by the action of heat.

More recently, Dixon and Jolly in Dublin and Askenasy in Germany have suggested the action of another force. They have shown that columns of water of very small diameter can so resist tensile strain that they can be lifted bodily instead of flowing along the channel. They suggest that the force of gravity is, in the first instance, one of the factors likely to draw partial attention to the pull upwards in consequence of decrease in pressure in the leaves. In these we have (1) the evaporation from the damp delicate cell-walls into the intercellular spaces; (2) the inhibition by the cell-wall of water from the vacuole; (3) osmotic action, consequent upon the subsequent increased concentration of the sap, drawing water from the wood cells or vessels which abut upon the leaf parenchyma. They do not, of course, deny the co-operation of the other forces which have been suggested, except so far as these are inconsistent with the motion of the water in the form of separate columns rather than a flowing stream. This view requires the existence of certain anatomical arrangements to secure the isolation of the separate columns, and cannot be said to be fully established.

**Nature of the Food of Plants.**—The recognition of the fundamental identity of the living substance in animals and plants has directed attention to the manner in which plants are nourished, and especially to the exact nature of their food. The idea was till recently accepted, that anything which plants absorbed from without, and which went to build up their organic substance, or to supply them with energy, or to exert some beneficial influence upon their metabolism, constituted their food. Now, as the materials which plants absorb are carbon dioxide from the air, and various inorganic compounds from the soil, and that the latter are absorbed not as such, but in the form of their complexes, which view is correct, vegetable protoplasm must be fed in a very different way from animal, and on very different materials. A study of the whole vegetable kingdom, however, negatives the theory that the compounds absorbed are the final and living food material. Animal and phanerogamic parasites can make no use of such substances as carbon dioxide, but draw elaborated products from the bodies of their hosts. Those fungi which are saprophytic can only live when supplied with the products of the autolytic processes of the tissues of the hosts, which they derive from decomposing animal or vegetable matter. Even in the higher flowering plants, in which the processes of the absorption of substances from the environment has been most fully studied, the food in the young sporophyte is closely related to that absorbed by the young sporophyte and prothallus of the group last mentioned. When the sporophyte first begins its independent life—when, that is, it exists in the form of the embryo in the seed—its living substance has been assembled by utilizing the simple inorganic compounds spoken of. Its nutritive power is supplied to it in the shape of certain non-organic substances which have been stored in some part or other of the seed, sometimes even in its own tissues, by the parent plant from which it springs. When the tuber of a potato begins to germinate, its roots are put into the water, the accumulated store of nutritive material which has been laid up in the cells of the tuber. If we examine the seat of active growth in a young root or twig, we find that the cells in which the organic substances of the protoplasm are stored begin to absorb the precipitated by from the water. The protoplasm being formed and distributed, we do not find what materials are deposited in the seed, and which become exhausted by consumption as growth and development proceed. There are, of course, the great classes of foodstuffs on which animal protoplasm is nourished, and whose presence renders seeds such valuable material for animal consumption. They are mainly carbohydrates such as starch and sugars, fats, proteins, etc., which, if an animal gains entry to them, are used by the cells of the animal organism in one or another of the processes of respiration. Moreover, the stationary habit of plants, and the almost total absence of locomotion, makes it impossible for them to seek their food.

The Special Apparatus of Plants for constructing Food. —The experiments of the previous chapter show us very simply the way plants are furnished with a constructive mechanism by which they are enabled to fabricate the food on which they live from the inorganic, gaseous and liquid matters which they absorb. The fact that the absorption does not render these substances food, they are taken in not as food, but as raw material, in the action of this constructive mechanism, and by it to be converted into substances that can nourish protoplasm, both vegetable and animal. It is sometimes forgotten, that when discussing questions of animal nutrition, that the food materials provided to animals are prepared originally from inorganic substances in exactly the same way, in exactly the same place, and by the same machinery, which is called the chlorophyll apparatus of the vegetable kingdom. A consideration of these facts points out, that an understanding of the rôle of the chlorophyll apparatus, is one of the first steps in understanding the fundamental metabolism of the organism, and capable of being dissociated, in theory at least, from its own special means of nutrition, if by the latter term we understand the appropriation by the protoplasm of the materials so assimilated.

The chlorophyll apparatus of plants demands a certain description. It consists essentially of a number of minute corpuscles or plastids, the protoplastic substance of which is impregnated with a green colouring matter. These bodies, known technically as chloroplasts, are found embedded in the protoplasm of the cells of the mesophyll of foliage leaves, of certain of the cells of some of the leaves of the flower, and of the cortex of the young twigs and petioles. Usually
they are absent from the cells of the epidermis, though in some
of the lower plants they are met with there also. The plastids are not
rigidly embedded in the cytoplasm, but are capable of a certain
amount of movement therein. Each is a small protoplastomic
body, bounded by a limiting membrane, composed of the same
material, and containing within itself the chlorophyll.
Chlorophyll is contained in a form of solution. Various solvents,
such as benzene, alcohol and chloroform, will dissolve out the
pigment, leaving the plastid colourless. Chlorophyll is not soluble
in water, except when it is rendered alkaline.
These plastids are especially charged with the duty of manufacturing
carbohydrates from the carbon dioxide which the air contains,
and which is absorbed from it after it has entered the intercellular
passages of the leaf. This, the plastid, is essentially a plant cell organelle
which is almost entirely occupied by carbohydrate-containing plastids.
This action is found to take place only in the presence of light, preferably
moderate sunlight. The reason for the distribution of the plastids as described above is consequently seen. The relation of the chloroplasts to their surrounding cytoplasm, which is the solution of the pigment is placed in the path of a beam of light which is
then allowed to fall on a prism, the resulting spectrum will be
found to be modified. Instead of presenting the appearance of a
continuous band in which all the colours are represented, it is
interrupted by seven vertical dark spaces. The rays which in the
absence of the solution of chlorophyll would have occupied those
spacnes have no power to pass through it, or in other words chlorophyll
absorbs those particular rays of light which are missing.
The absorption of these rays implies that the pigment absorbs
radiant energy from the sun, and gives some explanation of its
power of constructing the carbohydrates which has been mentioned as
a necessary part of its duty. This apparent contradiction is not yet
completely understood at present, nor can we say exactly what
is the part played by the pigment and what is the role of the protoplast
of the plastid. It is not certain either whether the action takes place in the chloroplast, or whether it is concerned, and if so how far, with
the construction of proteins also.
As the action of the chloroplast apparatus is directly dependent
upon the light, the plastids are, subject to extensive modifications in
the manufacture of carbohydrates or whether it is concerned, and if so how far, with
the construction of proteins also.
Photosynthesis.—In the presence of light and when the plant is
subject to such conditions, every cell of the leaf is occupied in the manufacture of
organic salts, particularly certain compounds of potassium, are
apparently necessary, but they seem to take no part in the chemical changes which take place.
The original hypothesis of Bayeury suggested that the course of events in the following: the carbon dioxide is decomposed into carbon monoxide and oxygen, while water is
simultaneously split up into hydrogen and oxygen; the hydrogen
and the carbon monoxide unite to form formaldehyde and the oxygen
is evolved. This view has now been satisfactorily proved, though it has been obtained from certain leaves by distillation. Certain Algae have been found capable of forming nutritive carbohydrates in darkness, when supplied with a
combination of this body with sodium-hydrogen-sulphite. But it is
certain that it can only be present in a cell in very small amount
at any moment, for an extremely dilute solution acts as a poison
to protoplasm. If formed, as it probably is, it is immediately
decomposed into water and oxygen, and so rendered incapable of exerting its poisonous action.
Bayeury’s hypothesis was entertained by botanists partly because it
explained the gaseous interchanges accompanying photosynthesis.
These were always accompanied by an exhalation of an equal volume of oxygen.
Recent investigations have confirmed Bayeury’s view of the formation of formaldehyde, but a different explanation has been recently
advanced. The postulated identity of formaldehyde and carbon monoxide has been satisfactorily proved, though it has been obtained from certain leaves by distillation. Certain Algae have been found capable of forming nutritive carbohydrates in darkness, when supplied with a

of nitrogen. As this is not the incorporation of either into the living substance, but just its manufacture into the complex substances which we find in the plant, it seems preferable to term the process "assimilation" to the processes by which foods are actually taken into the protoplasm.

Symbiotic green plants possess a very complete mechanism for the manufacture of their different foodstuffs, it is not always exercised to the fullest extent. Many of them are known to supplement it, and some almost entirely depend on it, owing to the plant having a fully prepared condition from their environment. It may be that they procure it from decomposing organic matter in the soil, or they may get it by absorption from other plants to which they attach themselves, in the same manner that the water plant is supposed to do. Many of them, and this includes the Fungi, and a single species of Fungi may enter into symbiosis with several green plants. The Fungi that have been discovered taking part in the symbiosis include *Eurotium*, *Pythium*, *Blotus*, *Aracis*, *Lentren*, and many other species. Though it is very probable that these forms of symbiotic action are not the only ones that exist, there is no evidence that they are the only ones that have been discovered.

All the known species belong to the Oomycetes, the Pyrenomycetes, the Ascomycetes or the Gasteromycetes. The habit of forming mycorrhizas is found more frequently in warm climates than cold; indeed, the percentage of the flora exhibiting this characteristic is greater with a certain regularity from the Arctic Circle to the equator.

**Fixation of Nitrogen**—Another, and perhaps an even more important, instance of symbiotic association has come to the front during the last few years. It is the fixation of atmospheric nitrogen by the members of the Order Leguminosae, and certain bacterium-like forms which find a home within the tissues of their roots. The importance of the symbiosis can only be understood by considering the relationship in question in reverse, and with this view in mind, recall that the view that this might be the source of the combined nitrogen found in different forms within the plant, was critically examined, particularly by Bouscault, and later by Lawes and Gilbert, to whom, after Dumas and Pasteur, the honour of the discovery belongs. The root only takes nitrogen into its substance when it is presented to its root in the form of nitrates of various metals, or compounds of ammonia. Many writers in recent years, among whom may be named Cottrell, and others, have shown that the Leguminosae as a group form conspicuous exceptions to this rule. While they are quite capable of taking up nitrates from the soil where and as long as the soil contains the nitrates, they have been found to contain no combined nitrogen at all, deriving their supplies of this element in these cases from the air. The phenomena have been the subject of very careful and critical examination for many years, and may be regarded as a more or less accurate account of the atmospheric nitrogen by the higher plants seems to be confined to this solitary group, though it has been established by many observers, with more or less emphasis that it is shared by others. Frank has claimed to have found oats, buckwheat, spurry, turnips, mustard, potatoes and Norway maples exercising it; Noble and others have imputed its possession to *Elaeagnus*. There is little direct evidence pointing to this extension of the power, and many experimenters directly contradict the statements.

The power exercised by the Leguminosae is associated with the presence of curious tubercular swellings upon their roots, which are developed at a very early age, as they are cultivated in ordinary soil. If experimental plants are grown in sterilized soil, these swellings do not appear, and the plants then use the atmosphere as their source of atmospheric nitrogen. The swellings have been found to be due to a curious hypertrophy of the tissues of the part of the cells being filled with an immense number of minute bacterium-like organisms of the *V*, *X*, or *Y* shape. The occurrence of these structures has been studied by many observers, both in England and on the continent of Europe. They appear to be present in large numbers in the soil, and to infect the Leguminous plant by attacking its root-hairs. One of these hair can be seen to be infected by the atmospheric nitrogen, and the hair, which does not fuse with the contents of the root-hair, whose protoplasm remains quite distinct and separate. After making its way into the interior, the intruder sets up a considerable trophy of the tissue, which is usually an eye-bright, or in fact, a whole system of cells. The core of differentiation, branches of the vascular bundles of the root being supplied to it. The rod-like bodies from the interior of the tube, which has considerable resemblance to the zoögea of many Bacteria, and to the protoplasmic filaments of the *Lactarius*, quickly fill it, increasing by a process of branching and fission. When this stage is reached the invading tubes and their ramifications frequently disappear, leaving the cells full of the bacteria, as they have been called. When the root dies later such of these as remain are discharged into the soil, and are then ready to infect new plants. In some cases the zoögea thread or tube has not been seen, the organism consisting entirely of the bacterioids.
This peculiar relationship suggests at once a symbiosis, the Fungus gaining its nutrient mainly or entirely from the green plant, while the latter in some way or other is able to utilize the free nitrogen of the air. The exact way in which the utilization or fixation of the nitrogen is brought about is not understood. We have certain support, therefore, that the second of them appears the more probable.

These are: (1) That the green plant is so stimulated by the symbiotic association which leads to the hypertrophy, that it is able to take up the nitrogen; and (2) that the nitrogen is assimilated in the green plant, and that the fixation of the gas is carried out by the fungal organism either in the soil or in the plant, and that the nutritious substance so produced is absorbed by the organism, which is in turn consumed by the green plant. Certain evidence which supports this view will refer to later in the chapter.

Whichever opinion is held on this point, there seems no room for doubt that the fixation of the nitrogen is concerned only with the root, and that the green leaves take no part in it. The nodules, in fact, take the nitrogen out of the air, and the plant part is used simply as a place of storage. Ward has directed attention to several points of this treatment which bear out this view. They are supplied with a regular system of conducting vascular bundles communicating with those of the roots, and the substances are accumulated in the roots, or for completion if the nodule is killed and dehydrated, the plant part is to be returned to the soil. The presence of such active tissues is alkaline, which has been interpreted as being in accordance with Loe’s hypothesis of the light protoplasm in presence of light nitrogen. The free nitrogen can build up ammonium salts in a third similar body. It is, however, present entirely unknown what substances are formed at the expense of the atmospheric nitrogen.

The idea that the atmospheric nitrogen is gradually being used up by the earth has been long entertained, and has been supported by evidence which has come to light during the last few years. The plant is a careful observer, and is able to detect in the slightest changes in its surroundings. Thus, for example, the green algae, when the fertilized part of the bodies of the fern, is able to take up the nitrogen from the air by means of the chloroplasts. The algae include Nostoc, Cystosoccus, Cylindrospermum and a few other forms. In the synthesis the algae are supplied with nitrogen by the bacteria, and in return provide the bacteria with the necessary organic matter. The process is thus an intimate one, with the two organisms working in perfect harmony, each supplying the other with what it needs. The algae are thus the nourishment of the bacteria, and the latter provide the algae with the necessary organic matter for their growth and development.

Nitrogen in the Soil.—Another aspect of the nitrogen question has been the subject of much investigation and controversy since 1877. The round of changes which nitrogenous organic substances undergo in the soil has been of great interest to botanists, and the study of these processes has been of great value in practical agriculture. The various changes which take place in the soil have been classified by some workers as follows: (1) the formation of organic matter by the action of microorganisms on the remains of dead plants and animals; (2) the decomposition of this organic matter by the action of microorganisms; (3) the decomposition of the organic matter by the action of microorganisms; (4) the absorption of the organic matter by plants; (5) the absorption of the organic matter by animals; (6) the absorption of the organic matter by microorganisms.

According to these views, the nitrogenous organic substances are ultimately reduced to water and carbon dioxide, and the carbon dioxide is oxidized by the action of microorganisms, while the water is absorbed by the plants and animals. The process is thus a continuous one, and the nitrogenous organic substances are continually being removed from the soil and returned to the atmosphere, where they are reabsorbed by plants and animals.

Enzymes.—The agents which effect the digestive changes in plants have been named enzymes, and are of two sorts: (1) enzymatic, which is in many cases identical with those of animal origin; and (2) non-enzymatic, which is in many cases identical with those of natural origin. A vast number of them have been discovered, and many have been investigated, and many have been found to be essential for the activities of the organism. The enzymes are a group of proteins, which are in many cases identical with those of animal origin. They are usually classified according to the materials on which they act, and we may here notice especially four principal groups, the members of which take part in the digestion of reserve materials as well as in the processes of assimilation. These enzymes are: (1) the proteolytic enzymes, which digest proteins; (2) the peptidases, which digest polypeptides; (3) the amylases, which digest starch; (4) the lipases, which digest fats.

Among those which act on carbohydrates the most important are: the two varieties of diastase, which convert starch into maltose or malt sugar; inulase, which forms fructose from inulin; invertase, which converts sucrose into glucose and fructose; glucosase or maltase, which produces glucose from maltose; and cyclase, which hydrolyses cellulose. Another enzyme which does
not appear to be concerned with digestion so directly as the others is peptase, which forms vegetable jelly from pectic substances occurring in the cell-wall. The enzymes which act upon glucosides are many; the best known are endo(poly)saccharases, which split respectively amygdalin, a special glucoside of certain plants of the Rosaceae; and sinigrin, which has a wide distribution among those of the Cruciferae. Others of less frequent occurrence are erythroslyn, rhamnase and gaultherase. The proteolytic enzymes, or those which digest proteids, are usually divided into two groups, one which breaks down ordinary proteids into diffusible bodies, known as peptones, which are themselves proteid in character. Such an enzyme is the pepsin of the stomach, an enzyme which results from the digestion of the peptones and breaks them down into the amino-acids of which we have spoken before. This group is represented by the erepsin of the pancreas and other organs. A third enzyme, the trypsin of the pancreas, is probably the most powerful of all, and its task is to transform all the proteins of the living substance into an enzyme, which has been called lipase. It splits it into a fatty acid and glyc erine, but seems to have no further action. The distribution of these transformations have not yet been completely followed.

Oxidases.—Another class of enzymes has been discovered, of which the best known is the oxidase. These enzymes act on oxygenates matter the most prominent. These respiratory processes are associated with the liberation of energy by the protoplasm, energy which it applies to various processes. The assimilation of complex foods consequently may be regarded as supplying the protoplasm with a source of energy. Respiration, then, is a process of the greatest importance, its effects being brought about by the action of a substance, known as adenosine triphosphate (ATP), which is formed in the cells of the living organism, and which is used in the process of respiration as a fuel. The process of respiration is essentially a process of oxidation, in which the oxygen is combined with the hydrogen of the carbohydrate, and the energy thus liberated is used to supply the needs of the cell. This energy is stored in the form of ATP, which is then used to power the many processes of the cell, including the synthesis of proteins and the growth of new cells.

Supply and Distribution of Energy in Plants.—It is well known that one of the conditions of life is the maintenance of the process which is known as respiration. It is marked by the constant and continuous liberation of energy, in the form of heat and light, from the tissues of the living organism. The processes of respiration may be divided into two main types, one of which is the process of oxidation, in which the oxygen is combined with the hydrogen of the carbohydrate, and the energy thus liberated is used to supply the needs of the cell. The other type of respiration is that which takes place in the mitochondria, in which the oxygen is combined with the hydrogen of the carbohydrate, and the energy thus liberated is used to supply the needs of the cell. This energy is stored in the form of ATP, which is then used to power the many processes of the cell, including the synthesis of proteins and the growth of new cells.

The question of the distribution of energy in the protoplasm is one of great importance, and one which has been the subject of much study. The distribution of energy in the protoplasm is determined by the nature of the organism, and by the conditions under which it is grown. In general, the distribution of energy is such that the energy is used in the processes which are most essential to the survival of the organism. Thus, in the roots of a plant, the energy is used to supply the needs of the root system, and to power the growth of new roots. In the leaves of a plant, the energy is used to power the processes of photosynthesis, and to supply the needs of the shoots. In the stems of a plant, the energy is used to power the processes of growth, and to supply the needs of the leaves and the roots. The distribution of energy in the protoplasm is thus determined by the nature of the organism, and by the conditions under which it is grown.
the framework of the fabric of the cell, and the construction of a continuously increasing skeleton; part is used in maintaining the temperature of the plant, part in constructing various substances which are met with in the interior, which serve various purposes in the working of the vital mechanism. A great part is utilized in that increase of the body of the plant which we call growth.

Growth, as usually spoken of, includes two essentially different processes. The first of these, which we may call in brief protoplast formation, is the manufacture of additional quantities of living substance. The second, which is usually included in the term, is the increase of such accessaries of living substance as are necessary for its well-being. The cell wall and the various products found in growing cells. There is a clear difference between these two categories. The formation of living substance is a process of building up from simple or relatively simple materials; the construction of supporting structures is due to the living substance after its original formation, and is attended by a partial decomposition of such living substance. Growth is always going on in plants while they are alive. Even the oldest trees show that increase of bulk is always going on; in such trees death is present but not yet apparent. The more advanced stages of this process are known to the botanist as the process of growth.

If we consider the behavior of a growing organ such as a root, we find that, like a cell, it shows a grand period of growth. Just behind its apex the cells are found to be all in process of active division. Growth is small, and consists mainly in an increase of the protoplast and its various products. We have not yet reached a certain size. As new cells are continually formed in the meristicous mass those which are farthest from the apex gradually cease to divide and a different process of growth takes place in them, which may be called protoplastification. This process is associated with the establishment of considerable hydrostatic pressure in them, thus causing the bulk of the cells to be greatly enlarged. Here it is that the actual extension in length of the root takes place, and the cell reaches its maximum point of the grand period. They then gradually lose the power of growth, the oldest ones or those farthest from the apex parting with it first, and pass gradually over into the condition of the permanent tissues.

The growth of the leaf is at first apical, but this is not very prolonged, and the subsequent enlargement is due to an intercalary growing region near the base.

In the lowest plants growth may be co-extensive with the plant-body; in all plants of a complex order of growth is due to the increased tissue in parts of it associated with the formation of new protoplasts or cells. These regions have been called growing points. In such stems and root as increase in thickness there are other growing regions, which constitute the cylindrical surface of the stem or plant. By the multiplication of the protoplasts in these meristematic areas the surface of the plant is increased.

In other words, as these growing regions consist of cells, the growth of the entire organ or plant will depend only upon the behavior of the cells or protoplasts of which the meristematic tissues are composed.

The growth of a cell will be found to depend mainly upon five conditions: (1) There must be a supply of nutritive or plastic substances, or protoplasts, the living substance of the cell or tissue to be used. (2) There must be a supply of water to such an extent as to set up a certain hydrostatic pressure in the cell, first of all cytoplasm, and then the protoplasm. (3) The supply of water must be associated with the formation of osmotic substances in the cell, or it cannot be made to enter it. (4) The cell must have a certain temperature, for the activity of a protoplasm is only possible within certain limits, whether of heat or cold. (5) There must be a supply of oxygen to the growing cell, for the protoplasm is dependent upon this gas for the performance of its vital functions, and particularly for the liberation of the energy which is demanded in the course of growth.

The growth of the cells is attended by the growth in surface of the cell wall, and as the latter is a secretion from the protoplasm, such a decomposition cannot readily take place unless oxygen is admitted to it. When these conditions are present, the increase of the growth of a cell appears to be the following: The young cell, immediately it is cut off from its fellow, absorbs water, in consequence of the presence in it of osmotic active substances. With the water it receives the various nutritive substances which the former contains in solution. There is set up at once a certain hydrostatic pressure, due to the turgidity which ensues upon such absorption, and the extensible cell wall stretches, at first in all directions. The growth of the cell is carried on uniformly in all directions, the turgidity matter for a matter of time keeps pace with the increased size of the cell, but by and by it becomes vacuolated, and more and more water is attracted into the interior. Eventually the protoplasm usually forms only a lining to the vacuolated mass, and the large vacuole becomes the centre. The growth of the protoplasm, though considerable, is therefore not commensurate with the increase in the size of the cell. The stretching of the cell wall by the hydrostatic pressure is fixed in the very way in which most protoplasmic deposits arise in the original wall, which, as it becomes slightly thicker is capable of still greater extension, much in the same way as a thick band of India rubber is capable of undergoing greater stretching than a thin one. Thus the growth is at first stretching caused by turgidity, and secondly to the formation and deposition of new substance upon the old. When the limit of extensibility is reached the cell wall increases in thickness from the concave side of the latter of the two processes.

The rate of growth of a cell varies gradually throughout its course; it begins slowly, increases to a maximum, and then becomes slower till it stops. The time during which these regular changes in the rate can be observed is generally spoken of as the grand period of growth.

Nervous System of Plants.—So far we have considered the plant almost exclusively as an individual organism, carrying out its own vital processes, and unaffected by its surroundings except in so far as these supply it with the materials for its well-being. When we consider, however, the great variability in those surroundings and the consequent changes a plant must encounter, it appears obvious that interaction and adjustment between the plant and its environment must be constant and well balanced. That such adjustment shall take place postulates a part of the plant a kind of perception or appreciation of the changing conditions which affect it.

Careful examination soon shows an observer that such perceptions exist, and that they are followed by certain purposeful changes in the plant, sometimes mechanical, sometimes chemical, the object being evidently to secure some advantage for the plant, to ward off some danger, or to extricate it from some difficulty. We may speak, indeed, of the plant as possessed of a rudimentary nervous system, by the aid of which necessary adjustments are brought about. The most constantly occurring changes that beset a plant are connected with illumination, temperature, moisture, and contact with foreign bodies. Setting aside other susceptibilities, we have evidence that most plants are sensitive to all these.

If a growing stem receives stronger illumination on one side than another, its apex slowly turns from the vertical in the direction of the light source, continuing its change of position until it is in a direct line with the incident rays. If a root is similarly illuminated, a similar change of direction of growth follows.
in this case the organ grows away from the light. These movements are spoken of as heliotropic and apheliotropic curvatures. The purpose of the movements bears out the contention that the plant is trying to adjust itself to its environment. The stem, by pointing directly to the light source, secures the best illumination possible for all of its leaves, the latter being distributed symmetrically around it. The root is made to press its way into the darker cracks and crannies of the soil, so bringing its root-hairs into better contact with the particles round which the hygroscopic water hangs. Leaves respond in another way to the same influence, placing themselves across the path of the beam of light.

Similar sensitiveness can be demonstrated in other cases. When a root comes in contact at its tip with some hard body, such as might impede its progress, a curvature of the growing part is set up, which takes the young tip away from the stone, or what-not, with which it is in contact. When a sensitive tendril comes in contact with a foreign body, its growth becomes so modified that it twines round it. Many instances might be given of appreciation of and response to other changes in the environment by the growing parts of plants; among them we may mention the opening and closing of flowers during the days of their expansion. One somewhat similar phenomenon, differing in a few respects, marks the relation of the plant to the attraction of gravity. Observation of germinating seedlings makes it clear that somehow they have a perception of direction. The young roots grow vertically downwards, the young stems vertically upwards. Any attempt to interfere with these directions, by placing the seedlings in abnormal positions, is frustrated by the seedlings themselves, which change their direction of growth by bringing about curvatures of the different parts of their axes, so that the root soon grows vertically downward again and the stem in the opposite direction. Other and older plants give evidence of the same perception, though they do not respond all in the same way. Speaking generally, stems grow upwards and roots downwards. But some stems grow parallel to the surface of the soil, while the branches both of stems and roots tend to grow at a definite angle to the main axis from which they come. These movements are spoken of as different kinds of geotropic curvatures. This power of perception and response is not by any means confined to the growing organs, though in these it is especially striking, and plays a very evident part in the disposition of the growing organs in advantageous positions. It can, however, be seen in adult organs, though instances are less numerous.

When the pinnate leaf of a Mimosa pudica, the so-called sensitive plant, is pinched or struck, the leaf droops rapidly and the leaflets become approximated together, so that their upper surfaces are in contact. The extent to which the disturbance spreads depends on the violence of the stimulation—it may be confined to a few leaflets or it may extend to all the leaves of the plant. The leaves and leaflets of many plants, e.g. the telegraph plant, Desmodium gyrans, behave in a similar way under the stimulus of approaching darkness.

A peculiar sensitiveness is manifested by the leaves of the so-called insectivorous plants. In the case of Dionaea muscipula we find a two-lobed lamina, the two lobes being connected by a midrib, which can play the part of a kind of hinge. Six sensitive hairs spring from the upper surface of the lobes, three from each; when one of these is touched the two lobes rapidly close, bringing their upper surfaces into contact and imprisoning anything which for the moment is between them. The mechanism is applied to the capture of insects. When the leaf, or another of this insectivorous group, has leaves which are furnished with long glandular tentacles. When these are excited by the settling of an insect on the leaf they slowly bend over and imprison the intruder, which is detained there meanwhile by a sticky excretion poured out by the glands.

In both these cases the stimulation is followed, not only by movement, but by the secretion of an acid liquid containing a digestive juice, by virtue of which the insect is digested after being killed.

The purposeful character of all these movements or changes of position indicates that they are of nervous origin. We have in them evidence of two factors, a perception of some features of the environment and following this, after a longer or shorter interval, a response calculated to secure some advantage to the responding organ. We find on further investigation that these two conditions are traceable to different parts of the organs concerned. The perception of the changes, or, in other words, the reception of the stimulus, is associated for example, with the tips of roots and the apices of stems. The first recognition of a specially receptive part was made by Charles Darwin, who identified the perception of stimulation with the tip of the young growing root. Amputation of this part involved the cessation of the response, even when the conditions normally causing the stimulation were maintained. Francis Darwin later demonstrated that the tips of the plumules of grasses were sensitive parts. The responding part is situated some little distance farther back, being in fact the region where growth is active. This bending part has been proved to be insensitive to the stimuli. There is consequently a transmission of the stimulus from the sensitive organ to a kind of motor mechanism situated some little way off. We find thus three factors of a nervous mechanism present, a receptive, a conducting, and a responding part. The differentiation of the plant’s substance so indicated is, however, physiological only; there is no histological difference between the cells of these regions that can be associated with the several properties they possess. Even the root tip, which shows a certain differentiation into root cap and root apex, cannot be said to be a definite sense organ in the same way as the sense organs of an animal. The root is continually growing and so the sensitive part is continually changing its composition, cells being formed, growing and becoming permanent tissue. The cells of the tip at any given moment may be sensitive, but in a few days the power of receiving the stimulus has passed to other and younger cells which then constitute the tip. The power of appreciating the environment is therefore to be associated with the protoplasm only at a particular stage of its development and is transitory in its character.

What the nature of the stimulation is we are not able to say. The protoplasm is sensitive to particular influences, perhaps of vibrations, or of contact or of chemical action. We can imagine though perhaps only vaguely, the way in which light, temperature, moisture, contact, &c., can affect it. The perception of direction or the influence of gravity presents greater difficulty, as we have no clear idea of the form which the force of gravity takes. Recently some investigations by Haberlandt, Noll, Darwin and others have suggested an explanation which has much to recommend it. The sensitive cells may be clearly influenced in some way by weight—not the weight of external organs but of some weight within them. This may possibly be the cell sap in their interior, which must exercise a slightly different hydrostatic pressure on the basal and the lateral walls of the cells. Or more probably it may be the weight of definite particulate structures in their vacuoles. Many experiments point to certain small grains of starch which are capable of displacement as the position of the cell is altered. Such small granules have been observed in the sensitive cells, and there is an evident correlation between these and the power of receiving the geotropic stimulus. It has been shown that if the organ containing them is shaken for some time, so that the contact between them and the protoplasm of the cells is emphasized, the stimulus becomes more efficient in producing movement. This reduces the stimulus to one of contact, which is in harmony with the perception of movement in the same region of the exterior. The stimulating particles, whether starch grains in all cases, or other particles as well, have been termed statoliths.

We have spoken of the absence of structural differentiation in the sense organs. There is a similar difficulty in tracing the paths by which the impulses are transmitted to the growing and curving regions. The conduction of such stimulation to parts removed some distance from the sense organ suggests paths of transmission comparable to those which transmit nervous
impulses in animals. Again, the degree of differentiation is very slight anatomically, but delicate protoplasmic threads have been shown to extend through all cell-walls, connecting together all the protoplasts of a plant. These may well serve as conductors of nervous impulses. The nervous mechanism thus formed is very rudimentary, but in an organism the conditions of whose life render locomotion impossible great elaboration would seem superfluous. There is, however, very great delicacy of perception or appreciation on the part of the sense organ, stimuli being responded to which are quite incapable of impressing themselves upon the most highly differentiated animal.

The power of response is seen most easily in the case of young growing organs, and the parts which show the motor mechanism are mainly the young growing cells. We do not find their behaviour like that of the motor mechanism of an animal. The active contraction of muscular tissue has no counterpart in the plant. The peculiarity of the protoplasm in almost every cell is that it is especially active in the regulation of its permeability by water. Under different conditions it can retain it more strongly or allow it to escape more freely. This regulation of turgor is as characteristic of vegetable protoplasm as contraction is of muscle. The response to the stimulus takes the form of increasing the permeability of particular cells of the growing structures, and so modifying the degree of the turgidity that is the precursor of growth in them. The extent of the area affected and of the variation in the turgor depends upon many circumstances, but we have no doubt that in the process of modifying its own permeability by some molecular change we have the counterpart of muscular contractility.

The response made by the adult parts of plants, to which reference has been made, is brought about by a mechanism similar in nature though rather differently applied. If the leaf of Mimosa or Desmodium be examined, it will be seen that at the base of each leaflet and each leaf, just at the junction with the petiole, there is a region in which there is a relatively large development of succulent parenchyma on its upper and lower sides. In the erect position of the leaf the lower side has its cells extremely turgid, and the pulvinus thus forms a cushion, holding up the petiole. On stimulation these cells part with their water, the lower side of the organ becomes flaccid and the weight of the leaf causes it to fall. The small pulvin of the leaflets, by similar changes of the distribution of turgidity, take up their respective positions after receiving the stimulus. In some cases the two sides of the pulvini vary their turgidity in turns; in others only the lower side becomes modified.

Similar turgescence changes, taking place with similar rapidity in the midrib of the leaf of Dionaea, explain the closing of the lobes upon their hinge. More slowly, but yet in the same way, we may note the change in turgidity of certain cells of the Drosera tentacles, as they close over the imprisoned insect.

Organic Rhythm.—It is a remarkable fact that during the process of growth we meet with rhythmic variation of such turgidity. The existence of rhythm of this kind has been observed and studied with some completeness. It is the immediate cause of the phenomena of circumnutation, each cell of the circumnutation organ showing a rhythmic enlargement and decrease of its dimensions, due to the admission of more and less water into its interior. The restraint of the protoplasm changes gradually and rhythmically. The sequence of the phases of the rhythm of the various cells are co-ordinated to produce the movement. Nor is it only in growing organs that the rhythm can be observed, for many plants exhibit it during a much longer period than that of growth. It is easy to realize how such a rhythm can be modified by the reception of stimuli, and can consequently serve as the basis for the movement of the stimulated organ. This rhythmic affection of vegetable protoplasm can be observed in very many of its functions. What have been described as “periodicities,” such as the daily variations of root-pressure, afford familiar instances of it. It reminds us of a similar property of animal protoplasm which finds its expression in the rhythmic beat of the heart and other phenomena.

**PATHOLOGY**

"Phytopathology" or plant pathology (Gr. φυτολογία, plant), comprises our knowledge of the symptoms, causes, cures and remedies of the maladies which threaten the life of plants, or which result in abnormalities of structure that are regarded, whether directly injurious or not to life, as unsightly or undesirable. In its systematized form, as a branch of botanical study, it was born in the days of the famous botanist, Malti, who lived in the 17th century. It first received special attention about 1850, when the nature of parasitism began to be intelligible; but many disconnected references to diseased conditions of plants had appeared long before this. The existence of blights and mildews of cereals had been observed and recorded in very ancient times, as witness the Bible, where half a dozen references to such scourges occur in the Old Testament alone. The epidemic nature of wheat-rust was known to Aristotle about 350 B.C., and the Greeks and Romans knew these epidemics well, their philosophers having shrewd speculations as to causes, while the people held characteristic superstitions regarding them, which found vent in the dedication of special festivals and deities to the pests. Pliny knew that flies emerge from galls. The few records during the middle ages are borne out by what is known of famines and pestilence. Shakespeare's reference in King Lear (Act iii, sc. iv.) may be quoted as evincing acquaintance with mildew in the 17th century; as also the interesting Rouen law of Loverdo (1660), which in 1679 gave excellent figures and accounts of leaf-rolling and gall insects, and grew in 1682 equally good descriptions of a leaf-mining caterpillar. During the 18th century more academic treatment of the subject began to replace the scattered notes. Hales (1727-1733) discussed the rotting of wounds, cankers, &c., but much had to be done with the microscope before any real progress was possible, and it is easily intelligible that until the theory of nutrition of the higher plants had been founded by the work of Ingenhousz, Priestley and De Saussure, the way was not even prepared for accurate knowledge of cryptogamic parasites and the diseases they induce. It was not till De Bary (1866) made known the true nature of parasitic Fungi, based on his researches between 1853-1863, that the vast domain of epidemic diseases of plants was opened up to fruitful investigation, and such modern treatises as those of Frank (1880 and 1895), Sorauer (1880), Kirchner (1880), and several others made possible.

Plant pathology embraces several branches of study, and may be conveniently divided as follows:

1. The observation and accurate description of symptoms (Diagnosis).
2. The study of causes or agencies inducing disease (Aetiology).
3. The practise of preventive and remedial measures (Therapeutics).

In plants, however, the symptoms of disease are apt to exhibit themselves in a very general manner. Our perceptions differentiate but imperfectly symptoms which are due to very different causes and reactions, probably because the organization of the plant is so much less highly specialized than that of higher animals. The yellowing and subsequent casting of leaves, for instance, is a very general symptom of disease in plants, and may be induced by drought, extremes of temperature, insufficient or excessive illumination, excess of water at the roots, the action of parasitic Fungi, insects, worms, &c., or of poisonous gases, and so forth; and extreme caution is necessary in dealing with amateur descriptions of such symptoms, especially when the untrained eye has taken no acquaintance of, or is only vaguely observed, the numerous collateral circumstances of the case.

The causes of disease may be provisionally classified somewhat as follows, but it may be remarked at the outset that no one of
these proximal causes, or agents, is ever solely responsible; and it is very easy to err in attributing a diseased condition to any of them, unless the relative importance of primary and subordinate agencies is discoverable. For instance, a Fungus epidemic is impossible unless the climatic conditions are such as to favour the dispersal and germination of the spores; and when plants are killed off owing to the supersaturation of the soil with water, it is by no means obvious whether the excess of water and dissolved materials, or the exclusion of oxygen from the root-hairs, or the lowering of the temperature, or the accumulation of foul products of decomposition should be put into the foreground. In every case there are chains of causation concerned, and the same factors will be differently grouped in different cases.

Bearing in mind these precautions, we may classify the proximal causal agents of disease as follows:

I.—External agencies.

A. Soils.

1. Physical
   a. Material
   1. Temperature.
   b. Water.
   c. Atmosphere.

2. Chemical
   a. Animals.
   b. Plants.
   c. Atmosphere.

B. Living.

1. Temperature.
2. Illumination.
3. Other agencies.

II.—Internal agencies.

While such a classification may serve its purpose as a sort of index, it must be confessed that the limits of its usefulness are soon reached. In the first place, the so-called "internal causes" of disease is probably a mere phrase covering our ignorance of the factors at work, and although a certain convenience attaches to the distinction between those cases where tender breeds of plants apparently exhibit internal predisposition to suffer more readily from those other parasites, lower temperatures, excessive growth, &c.—as is the case with some grafted plants, cultivated hybrids, &c.—the mystery involved in the phrase "internal causes" only exists until we find what action of the living or non-living environment of the essential mechanism of the plant has upset its equilibration.

I.—Passing to the recognized external agencies, the physical condition of the soil is a fruitful source of disease. If too closely packed, the vegetable tissues present mechanical "asphyxiation" growths; if too retenitive of moisture, the root-hairs suffer, as already hinted; if too open or over-drained, the plant succumbs to drought. All those properties of soil known as texture, porosity, depth, inclination to the horizon, &c., are concerned here. By way of illustration, plants are traceable to the chemical composition of soils,—e.g., deficiency of nutritive salts, especially nitrates and phosphates; the presence of poisonous salts of iron, copper, &c., or (in the soil alone) the presence of alkalis; the presence of coal-gas and so forth. But it is worthy of special attention that the mere chemical composition of agricultural and garden soils is, as a rule, the least important feature about them, popular opinion to the contrary notwithstanding. Ordinary soils will almost always provide the necessary chemical ingredients if of proper physical texture, depth, &c. (see Fungi and Bacteriology).

As regards soil, its deficiency or excess is a relative matter, and although many valuable mineral substances are supplied by the action of Fungi and greenhouses controlled by amateurs depend on its misuses, water alone is probably never a primary cause of disease. Its over-supply is, however, a frequent cause of predisposition to the action of parasitic Fungi,—the "soil disease" and in saturated soils not only are the roots and root-hairs killed by asphyxiation, but the whole course of soil fermentation is altered, and it takes time to "sweeten" the ground by draining, because not only must the root-hairs be gradually washed out and the lost salts restored, but the balance of suitable bacterial and fungal life must be restored.

The atmosphere is a cause of disease in the neighbourhood of chemical works, coal-mines, volcanoes, &c., in so far as it carries acid gases and poisons to the leaves and roots; but it is usual to associate with it the action of excessive humidity which brings about these tender watery and more or less etiolated conditions which favour parasitic Fungi, and diminish transpiration and therefore nutrition. It is customary to speak of the disastrous effects of cold winds, snow, hail and frost, lightning, &c., under the heading of atmospheric influences, which only shows how more important it is to separate causes individually.

Turning to the non-material external agents, probably no factors are more responsible for ill-health in plants than temperature and light. Every plant is constrained to carry out its functions of germination, growth, nutrition, reproduction, &c., between certain limits of temperature, and somewhere between the extremes of these limits each function finds an optimum temperature at which it is most efficiently performed. If any of the functions is being equal, any great departure from this may induce pathological conditions; and many disasters are due to the failure to provide such suitable temperatures—e.g. in greenhouses where plants are visited by "evil" conditions, different parts of the same plant are kept together. Equally disastrous are those climatic or seasonal changes which involve temperatures in themselves not excessive but in wrong sequence; how many more useful plants could be grown this summer if we had a cool spell of May or open, clear weather followed by frosts of May and June! The indirect effects of temperature are also important. Trees, of which the young buds are "nipped" by frost, would frequently rank as the standard of the season if not for the fact that recent cold springs were not so often followed by frosts in May and June.

All chlorophyll plants require light, but in very different degrees, as exemplified even in the United Kingdom by the shade-bearing beech and yew contrasted with the light-demanding larch and birch; and as with temperature so with light, every plant and every organ of its own has its optimum illumination. The "drawn" or etiolated condition of over-shaded plants is a case in point, though here again the soft, watery plant often really succumbs to other causes (e.g., a parasitic Fungus)—supervening on its non-resistant condition.

Animals and plants as agents of disease or injury form part of the same subject—disease being the result of the struggle for existence between the suffering organism and its environment, living and non-living. The Vertebrata come within the scope of our subject, chiefly as destructive agents which cause wounds or devour young shoots and foliage, &c. Rabbits and other burrowing animals injure trees by gnawing spheres and birds strip off buds, horned carpet strip off bark, and so forth. It is among the Invertebrata that epidemics of destruction are referred to, though we should be well in mind that it is only the difference in numerical proportion that prevents our saying insects and animals injure plants in the same way that the term when speaking of blight insects; there is little consistency in the matter, as it is usual to speak of an invasion or scourge of locusts, caterpillars, &c. Insect injuries are very varied in degree and kind. Locusts devour all before them; caterpillars, &c., plant and necessitate the premature utilization of its reserves; other insects (e.g., Grapholitha) eat the buds or the roots (e.g., wireworms), and so maim the plant that its foliage suffers from want of nourishment and assimilation.

Many aphids, &c., puncture the leaves, suck out the sap, and induce various local deformations, arrest of growth, putrid swellings, &c., and if numerous the evils of defoliation may follow. The Eel-worms (e.g., Heterodera) are particularly injurious because they tunnel the roots; and so put the assimilating organs out of action in another way. It should be remembered that a single complete defoliation of a herbaceous annual may so incapacitate the assimilation that no store is left to supply the demands made upon the roots for another year; so that most little that feeble plants only come up. In the case of a tree matters run somewhat differently; most large trees in full foliage have far more assimilatory surface than is immediately necessary, and if the injury is confined to a single year it may be a small event in the life of the tree, but if repeated the camomile, bud-stores and fruiting may all suffer. Many larvae of beetles, moths, &c., bore into bark, and injure the cambium, or even the wood itself, and by their injurious action upon the woods assist in the transpiration current and the access of other parasites through the wounds are also to be feared in proportion to the numbers of insects at work. Various local hypertrophies, including galls, resemble the injuries mentioned above, and may be due partly to punctures of insects, or by the presence of eggs or larvae left behind. They may occur on all parts, buds, leaves, stems or roots, as shown by the numerous species of Cynips on oak, Phylloxera on vines, &c.

The local damage is small, but these hypertrophies, as a rule, increase, absorption and other functions, may be important if the numbers increase. In addition to insects, various kinds of worms, molluscs, &c., are sometimes of importance as pests. The so-called eel-worms (e.g., Heterodera) attack plants either in the grains of cereals, and every one knows how predatory slugs and snails are. (See Economic Entomology.)

Plants as agents of damage and disease may be divided into two classes so far as they are injurious through forming and so forth. In this case the formers do injury by dominating and shading more delicate species, or by gradually exhausting the soil, &c., and true parasites which actually live and on in the tissues of the plants. It must be remembered that phanerogams also include parasitic species—e.g., Crucina, Laronthus, Viscum, Thesium, Rhinanthus, &c., with various capacities for injury. These enemies are as a rule so conspicuous that
we do not look on their depredations as diseases, though the gradual deterioration of hay under the exhausting effects of root-parasites like Rhinanthus, and the onslaught of Cuscuta when unduly abundant, should teach us how unimportant to the definition the question of whether or not disease "exists".

It is, however, among the Fungi that we find the most disastrous and elusive agents of disease. Parasite Fungi may be, as regards their direct action, purely local—e.g. Schinia, which forms gall-like swellings on the stems and leaves; Melampsorium, which produces excrecences on juniper stems; numerous leaf Fungi such as Puccinia, Aecidium, Sphaerita, &c., causing yellow, brown or black spots on leaves; or Ustilago in the anthers of certain flowers. In such cases of direct action there may be no accommodation between host and parasite, and the effects of prolonged action and the summation of numerous attacks at numerous points are often enormous, certain of these leaf-diseases costing millions sterling annually to some planting and agriculture. Parasite Fungi may, however, produce more or less extensive effects in which there is accommodation between host and parasite.

Irritation and hypertrophy of cells are common signs of the presence of parasites, as evinced by the numerous malformations, galls, witches'-brooms, &c., on diseased plants. The now well-known phenomena of wound healing or cut-wound responses may act as stimuli to living protoplasm, and that respiratory action which is increased by chloroform, ether and even powerful mineral poisons, such as mercuric chloride, in minimal doses, offers some explanation of these phenomena of hypertrophy, "wound fever," or "callus formation.

But it is now clear that if an organism gains access to all parts of a plant, and stimulates all or most of its cells to hypertrophy, we may have the latter behaving abnormally—i.e. it may be discussed through the mediation of the medium in which it is situated. Thus, it is with Uromyces Pisii, the presence of which alters the whole aspect of the host-plant. If such a general parasite carries its activities farther, every cell may be killed and the plant fortieth destroyed— hence "infectious diseases." In such cases the parasite agent is local in its action, causing only a few cells to react, we have the various pimples, excrecences, outgrowths, &c., exhibited in such cases as Ustilago Maydis on the maize, various galls, witches'-brooms, &c.

It must not be overlooked that the living cells of the plant react upon the parasite as well as to all external agencies, and the nature of disease becomes intelligible only if we bear in mind that it consists mainly of phenomena of irritation, and that perfect accommodation between host and guest has been carried so far that each derives some benefit from the association—symbiosis, &c.

It is only within the last few years that we have been able to understand the phenomena of parasitism. The various groups of parasites are to a certain extent explained by the foregoing. In order that a Fungus may enter a plant, it must be able to overcome not merely the resistance of cell-walls, but that of the living protoplasm; if it cannot do this, it must remain putrefying as a mere saprophyte, e.g. Fumago, Herbelina, &c., or, at most, vegetate in the intercellular spaces and anchor itself to the cell-walls, e.g. Trichosporium. The inability to enter the cells may be due to the lack of chemotactic bodies, to incapacity to induce hypertrophy, and other phenomena. But when we have made the cell-walls penetrable, we still cannot ensure the establishment of the host Fungus, as many cases are known where the Fungus can break through the cell's first line of defence (cell-wall and protoplasmic lining); but the struggle goes on at close quarters, and various degrees of hypertrophy, disorganization of the cell, alteration in the coloration, &c., indicate the suffering of the still living cell. Finally, cases occur where the invader cell so adapts itself to the presence of the intruder that life in common—symbiosis—results. But whether the Fungus is or is not in symbiosis, it is in all cases the active growing "callus" developed at the surface of the wounded tissues of cuttings, budding, pruning, &c., that the healing and re-nourishment of tissues occur, which advantage is taken in the practice of what might well be termed plant surgery. It is the active growing that removes the incrustation, and many cell-walls that are in many cases not always obvious, whence an air of mystery regarding epidemics was easily created in earlier times. The spores of Rusts, Erysiphaceae and other Fungi may be conveyed from plant to plant on the external surface of large wheels of conidia, for which mice, rabbits, rats, &c., which rub their fur against the hymenophores. Seeds carry the spores of Sclerotinia as they do the pollen of the bilberries, and flies convey the conidia of ergot from grain to grain. Insects, indeed, are largely concerned in distributing Fungi, either on their bodies or via the alimentary canal. Worms bring spores to the surface of soil, ducks and other birds convey them on their muddy feet, and, as is well known, wind and other physical
PLANTS

agencies are very efficient in dissemination. The part played by man also counts for much. Gardeners and farm labourers convey spores from one bed or field to another; carted soil, manure, &c., may abound in spores of Smut, Puccarium, Polypore, and in scab; and the infested post and, in the carriage of such spores. Every time a carpenter saws fresh timber with a saw recently put through wood attacked with dry-rot, he risks infecting it with the Fungus; and similarly in pruning, in propagating by cuttings, and in grafting. The annual losses due to epidemic plant diseases attain proportions not easily estimated. As regards money value alone the following figures may serve in illustration. In 1862 the United States lost $2,000,000 in wheat, and almost the same amount in corn, due to the insect and other pests. The wheat-rust causes Australia £2,000,000 to £3,000,000 annually, and in 1891 alone the loss which Prussia suffered from grain-rusts was estimated at £20,000,000 sterling.

The results of the epidemic action of Fungi, plants, foresters, &c., from plant diseases have naturally stimulated the search for remedies, but even now the search is too often conducted in the spirit of the believer in quick medicines, although the agricultural world is awakening to the fact that before any measures likely to be successful can be attempted, the whole chain of causation of the disease must be investigated. Experience with epidemics, dearly bought in the past, has shown that one fruitful cause is the laying open to the inroads of some Fungi or insect, hitherto leading a quiet endemico life in the fields and forests, large tracts of its special food, along which it may range rampant without check to its dispersal, nutrition and reproduction. Compounding all of the previous conditions for the host-plant, leading to supposed vulnerability previously non-existent, would probably never have seen the light had the full significance of the truth been grasped that an epidemic results from the association of many factors, none of which, perhaps, are more than they do the host. It may be that in particular cases particular modes of cultivation disfavor the host; or that the soil, climate or seasons do so; but overwhelming evidence exists to show that the principal modes of epidemic action of Fungi, plants, foresters, &c., is that between nutrition, nutrition and reproduction of the pest, and the lesson to be learnt is that precautions against the establishment of such favouring conditions must be at the root of all successful preventative measures are devised to meet the various cases and to check the ravages already begun. The procedure consists in most cases of spraying the affected plants with poisonous solutions or emulsions, or spraying with dusts or powders. This is the least laborious of the remedial processes, and is generally considered to be the cheapest. The fumes of lethal gases. For the composition of the numerous liquids and powders special waters must be consulted, but the following principles apply generally. The poison must not be strong enough to injure the root or to kill all the plants. The history of the pest are not known; e.g., the application of ordinary antiseptic powders to leaves inside which a Fungus, such as a Uredo or Ustilago, is growing can only result in failure, and similarly if too strong a gas be selected. Numerous methods of preventing the spread of Fungi, or the migration of insects, or of trapping various animals; of leaving infested plants, and of birthing the number of plants, &c., are also to be found in the practical treatises. Numerous indirect methods, such as the grafting of less resistant on more vigorous stocks, or raising special late or early varieties by cross-fertilization, are also used. But the most important thing is that it must be understood that "resistant" in such cases usually means that some peculiarity of quick growth, early ripening or other life-features in the plant is for the time being taken advantage of. The resistance against epidemic pests is that of introducing other Fungi among the pests themselves—e.g., the infection of rats and mice with disease bacilli, or of locusts with insect-killing Fungi, and similar instances. That the encouragement of insectivorous birds has been profitable is well established, and it is equally well-known that their destruction may lead to disastrous insect plagues.

Diseases and Symptoms.—The symptoms of plant diseases are, as already said, apt to be very general in their nature, and are sometimes so vaguely defined that little can be learned from them as to the causes at work. We may often distinguish between primary symptoms and secondary or subordinate symptoms, but for the purposes of classification in an article of this scope we shall only attempt to group the various cases under the more obvious signs of disease exhibited.

1. Discolorations are among the commonest of all signs that a plant is "sickly" or diseased. The principal symptom may show itself in general pallor, including all cases where the normal healthy green hue is replaced by a sickly yellow, often distinctly colored. It may be due to insufficient illumination (Etiofation), as seen in geraniums kept in too shaded a situation, and is then accompanied by soft tissues, elongation of internodes, leaves of a abnormal shape and size, and the occurrence of certain fungal or bacterial infections. False etiolation may occur from too low a temperature, often seen in young wheats in cold springs. Cases of pallor due to too intense illumination and destruction of chlorophyll must also be reckoned. In a aphid-infested corn field where the chlorophyll remains in abeyance owing to a want of iron, and can be cured by adding ferrous salts. Lack of other ingredients may also induce chlorotic conditions. Yelling is a common symptom of water-logging, and reddening of leaves may be due to drought. Over-transpiration in bright windy weather, when the roots are not absorbing, often results in yellowing. In other cases the presence of insects, Fungi or poisons at the roots may be looked for. Albinism, with which variegated foliage may be considered, concerns a different set of causes, still obscure, and usually regarded as internal, though experiments go to show that various infections are infectious.

2. Symptoms of the United Kingdom, of which the red spots on leaves and other herbarious parts are common symptoms of disease, and often furnish clues to identification of causes, though it must be remembered that no sharp line divides this class of symptoms from the other groups. Such are due to Fungi, as indicated by the numerous "leaf diseases" described, but such is by no means always the case. The spot or patch is an area of injury; on or in it the cell-contents are suffering destruction by the direct action of the causative organism, the mechanical injury, and the plant suffers in proportion to the area of leaf surface put out of action. It is somewhat artificial to classify these diseases according to the colour of the spots, and often impossible, because the colours may differ according to the part attacked and the stage of injury attained; many Fungi, for instance, induce yellow spots which become red, brown or black as they get older and so on. White or grey spots may be due to Penicillium, Aspergillus, Scymnus, Sphaeria, &c., while the mycelium of which will be detected in the discoloured area; or they may be scale insects, or the results of punctures by Red-spider, &c. Yellow spots, and especially bright orange spots, commonly indicate Russula, Clavaria, Strobilomyces, Epithelium, Podostoma, Synchysium, Synchysium, &c., also induce similar symptoms. Certain Aphides, Red-spider, Phylloxera and other insects also betray their presence by such spots. It is a very common event to find the various stipples and variegations of saprophytes, particularly the variously-colored spots and dots characteristic of Phytothepha, Puccinia, &c., and black ones of Pucciniad, Ustilago, Rhynchos, &c. Both are common as advanced symptoms of destruction by Fungi and insects. Brown or black spots are characteristic of Phytothepha, Puccinia, &c., and black ones of Pucciniad, Ustilago, Rhynchos, &c. Both are common as advanced symptoms of destruction by Fungi and insects. Brown or black spots are characteristic of Phytothepha, Puccinia, &c., and black ones of Pucciniad, Ustilago, Rhynchos, &c. Both are common as advanced symptoms of destruction by Fungi and insects. Brown or black spots are characteristic of Phytothepha, Puccinia, &c., and black ones of Pucciniad, Ustilago, Rhynchos, &c. Both are common as advanced symptoms of destruction by Fungi and insects. Brown or black spots are characteristic of Phytothepha, Puccinia, &c., and black ones of Pucciniad, Ustilago, Rhynchos, &c. Both are common as advanced symptoms of destruction by Fungi and insects.
PLANTS

wounds due to plants which entwine, pierce or otherwise materially injure trees, &c., on a large scale.

4. Exudations.—Outgrowths, more or less abnormal in character, are frequent signs of diseased organs. They are due to hyper- trophy of those tissues which come in contact with each other and are maintained as a permanent source of irritation, and the regener- ativ tissues grow over the wound, and the insect or Fungus, on the other, destroying the new tissues as they are formed, results in irregular growths; the still uninjured cambium area grows thickening the branch, the dead parts, of course, remain unthickened, and the portion in which the Fungus is at work may for the time be growing more rapidly. Such cankers often commence in mere insect punctures, frost-buds, cracks in the cortex, &c., into which a germinating spore sends its hypha. The seriousness of the damage done is illustrated by the ravages of the larch disease, apple canker, &c.

5. Exudations and Rotting.—The outward symptoms of many diseases consist in excessive discharges of moisture, often accompanied by a color change, and putrefactive changes. Conditions of hyper-turgescence are common in herbaceous plants in wet seasons, or on overcrowded and in situations too moist for them. This unhealthy state is frequently due to the presence of certain bacteria, in other cases to the invasion by Fungi—e.g., Cucubospora, Compendia, Borysia, &c. That such over-turgescence should lead to the bursting of flaky fruits, such as gooseberries, tomatoes and grapes, is not surprising, nor can we wonder at the rotting of certain vegetables, such as turnips, and such fungi; and the same is true for bulbs and herbaceous organs generally. The rotting of rhizomes, roots, &c., also comes into this category; but while it is extremely difficult in given cases to point out the Fungi which cause the disease, many of the fungi and bacteria which have been so definitely associated with these root and beet-root, turnip disease, wet-rot of potatoes—that we have to consider each case separately. It is, of course, impossible to do this here, but I will mention of a few.

Honey-dew.—The sticky condition of leaves of trees—e.g., lime—in hot weather is owing to exudations of sugar. In many cases the punctures of Aphides and Cocccaeae are shown to be responsible for it. In others the occurrence is more difficult to trace. In all cases, instance is known where a Fungus—Claviceps—causes it. But in honey- dew may be excrusted by ordinary processes of over-turgescence pressing the liquid through wort-pores, as in the tropical Cucubospora. And honey-dew on leaves should afterwards serve as pabulum for Fungi—e.g., Fungus Jeninorum—not surprising, and the leaves of oaks are black with them.

Bulks.—A common event in the exudation of turbid, frothing fluids from wounds in the bark of trees, and the odours of putrefaction and even alcholic fermentation in these are sufficiently explained by the coexistence of albuminous and saccharine matters with fungi, yeasts and bacteria in such fluids. It is clear that in these the obvious symptom—turbidity—is the primary one. Some wound in the succulent tissues has become infected by the organisms referred to, and their continued action prevents healing. A number of these injuries, and the organisms of which, by the bye, are remarkable and interesting forms—multiply in the nutritious sap and ferment it. The phenomenon is, in fact, very like that of the fermentation of palm wine and pulque, where the juices are obtained from artificial cuts.

Carcinosis.—The blackened discoloration of wood due to the juices sucked out by Aphrophilus on herbaceous plants is a common one.

Bacteriosis.—Many of the plant diseases involving rot have been traced to the presence of a large number of bacteria, and in some cases—e.g., cabbage, rot, bull-rot of hyacinth, &c., there is evidence that bacteria are causally connected with the disease. It is not sufficient to find bacteria in the rotting tissues, however, nor even to be successful in infecting the plant through an artificial wound, unless very special and critical precautions are taken, and in many instances of the alleged cases of bacteriosis the saprophytic bacteria in the tissues are to be regarded as merely secondary agents.

6. Necrosis.—A number of diseases the obvious symptoms of which are the drying up and death of tissues, in many cases
PLANTS

ECOLOGY]

with secondary results on organs or parts of organs, may be brought
together under this heading. No sharp line can be drawn between
these diseases and some of the preceding, inasmuch as it often
depends on the external conditions whether necrosis is a dry-rot,
in the sense I employ the term here, or a wet-rot, when it would
come under the preceding category. The " dying back " of the
twigs of trees and shrubs is a frequent case. The cortical tissues
gradually shrink and dry up, turning brown and black in patches
or all over, and when at length the cambium and medullary ray
tissues dry up the whole twig dies off. This may be due to frost,
especially in " thin-barked " trees, and often occurs in beeches,
pears, &c.
or it may result from bruising by wind, hailstones,
gun-shot wounds in coverts, &c, the latter of course very local.
It is the common result of fires passing along. too rapidly to burn
the trees; and " thin-barked " trees hornbeam, beech, firs, &c.
may exhibit it as the results of sunburn, especially when exposed
to the south-west after the removal of shelter. The effects of frost
and of sunburn are frequently quite local. The usual necrosis of
the injured cortex occurs drying up, shrivelling, and consequent
stretching and cracking of the dead cortex on the wood beneath.
Such frost-cracks, sun-cracks, &c, may then be slowly healed over
by callus, but if the conditions for necrosis recur the crack may be
again opened, or if Fungi, &c, interfere with occlusion, the healing
is prevented; in such cases the local necrosis may give rise to
cankers. The dying back of twigs may be brought about by many
causes. General attacks of leaf-diseases invariably lead to starvation and necrosis of twigs, and similarly with the ravages of caterpillars and other insects.
Drought and consequent defoliation
result in the same, and these considerations help us to understand
how old-established trees in parks, &c, apparently in good general
health, become " stag-headed " by the necrosis of their upper
twigs and smaller branches: the roots have here penetrated into
subsoil or other unsuitable medium, or some drainage scheme has
deprived them of water, &c, and a dry summer just turns the scale.
Such phenomena are not uncommon in towns, where trees with
their roots under pavement or other impervious covering do well
for a time, but suddenly fail to supply the crown sufficiently with
water during some hot summer.
A large class of cases of departure from the
7. Monstrosities.
normal form, depending on different and often obscure causes,
may be grouped together under this heading; most of them are of
the kind termed Teratological, and it is difficult to decide how far
they should be regarded as pathological if we insist that a disease
threatens the existence of the plant, since many of these malformaparts, contortions
tions
e.g. double flowers, phyllody of floral
and fascinations, dwarfing, malformed leaves, &c. can not only
be transmitted in cultivation, but occur in nature without evident

domain of pathology, however, into touch with that of variation,
and we are profoundly ignorant as to the complex of external
conditions which would decide in any given case how far a variation
in form would be prejudicial or otherwise to the continued existence
Under the head of malformations we place cases of
of a species.
atrophy of parts or general dwarfing, due to starvation, the attacks
of Fungi or minute insects, the presence of unsuitable food-materials
and so on, as well as cases of transformation of stamens into petals,
carpels into leaves, and so forth. Roots are often flattened, twisted
and otherwise distorted by mechanical obstacles; stems by excess
of food in rich soils, the attacks of minute parasites, overgrowth
by climbing plants, &c. Leaves are especially apt to vary, and
although the formation of crests, pitchers, puckers, &c, must be
put down to the results of abnormal development, it is often difficult
to draw the line between teratological and merely 'varietal phenomena. For instance, the difference between the long-stalked and
finely-cut leaves of Anemone attacked with rust and the normal
leaves with broad segments, or between the urceolate leaves ocin these
casionally found on cabbages and the ordinary form
;

—

—

—

—

—

—

cases undoubtedly pathological and teratological respectively is
nothing like so great as between the upper and lower normalleaves of many Umbelliferae or the submerged and floating leaves
of an aquatic Ranunculus or Cabomba. When we come to phenomena such as proliferations, vivipary, the development of " Lammas
shoots," adventitious buds, epicormic branches, and to those malformations of flowers' known as peloria, phyllody, virescence, &c.
while assured that definite, and in many cases recognizable, physiological disturbances are. at work, we find ourselves on the borderland
between patholpgical and physiological variation, where each case
must be examined with due regard to all the circumstances, and
no generalization seems possible beyond what has been sketched.
This is equally true of the phenomena of apogamy and apospory
in the light of recent researches into the effects of external conditions on reproduction.

This sketch of an enormous subject shows us that the pathology
is a special department of the study of variations which
threaten injury to the plant, and passes imperceptibly into the

of plants

759

study of variations in general.

Moreover, we have good reasons

for inferring that different constellations of external causes

may

determine whether the internal physiological disturbances
induced by a given agent shall lead to pathological and dangerous
variations, or to changes which may be harmless or even advantageous to the plant concerned.

Introduction.

Ecology of Plants
word ecology is derived from

— The

01/cos,

a

house (habitat), and X670J, a discourse. As a botanical term,
ecology denotes that branch of botany which comprises the
study of the relations of the individual plant, or the species, or
Following Schroter 1
the plant community with the habitat.
(Flahault and Schroter, 1910 24), the term autecology may be
used for the study of the habitat conditions in relation to the
single species, and the term synecology for this study in relation
to plant communities.
From the phytogeographical standpoint, ecology is frequently
termed ecological plant geography. Thus Warming 2 (1901 1 and 2)
1
Flahault and Schroter, Phytogeographical Nomenclature: reports
and propositions (Zurich, 1910).
2
:

:


plants which, like deciduous trees and bulbous plants, are hygrophytes during one season of the year and xerophytes during another season of the year. Such plants, which comprise the great majority of the species of the central European flora, Schimper termed *trophophytes*.

Recently, Warming 1 (1900 : 130), assisted by Vahl, has modified his earlier classification, and adopted the following:

A. The soil (in the widest sense) is very wet, and the abundant water is available to the plant (at least in hygrophytes).

1. Hygrophytes.—These are plants of the plankton, or microphytes that float free on water, of the *pleuston*, or macrophytes which float on or are suspended in water, and all aquatic plants which are fixed to the substratum.

2. Helophytes.—These are marsh plants which normally have their roots in water where floating and foliage are more or less aerial. Warming admits there is no sharp limit between marsh plants and land plants; and it seems equally obvious that there is no sharp limit between some of his helophytes and some of his hygrophytes. For example, the difference between helophytes and hygrophytes often lies in the amount of air in plants with floating leaves; such as the yellow water-lily (*Nymphaeae luteo-album*) and those with erect leaves, such as *Typha angustifolia*, is probably more apparent than real. Among helophytes, Warming places plants of the reed swamp, and includes such trees as the elder (*Alnus roundifolia*), willows (*Salix alba*, *S. fragilis*, *S. cinerea*, *S. pentandra*), birch, and pine, when these grow in marshy places.

B. The soil is physically dry.

3. Oxylphytes.—These plants, sometimes spoken of as "log xerophytes", grow in soils which contain an abundance of free humous compounds, and include plants which grow on fens and moors.

4. Psychrophytes.—These include the plants which grow on the cold shores of sub-arctic and polar districts.

5. Halophytes.—These are plants which grow on saline soils.

C. The soil is physically dry.

6. Lithophytes.—These are plants which grow on "true rock," but not "on the loose soil covering rock, even though this may enter in the composition of the vegetation growing in crevices and niches" (Warming, 1900 : 243). Many Algae, lichens, and mosses are included among lithophytes, and also *Aizoon*, *Lithophyllum*, *Scaphyglottis*, *Sclerophyllous* (which occur on dry peat and bare rock), *Psilophytes*. Under *Lithophyllum* are placed *Lithothamnion* (which grow on bare rock), *Sedum* (which grow on dry soils), and *Arenaria* (which grow on dunes, mud banks, and sand-dunes). For plants of the reed swamp, and includes such trees as the elder (*Alnus roundifolia*), willows (*Salix alba*, *S. fragilis*, *S. cinerea*, *S. pentandra*), birch, and pine, when these grow in marshy places.

D. The climate is very dry, and the properties of the soil are decided by climate.

7. *Sphagnum* group.—These are plants which grow on sand and gravel. Plants of sand-dunes, whether in maritime or inland localities, are *Sphagnum* group, as well as plants (such as *Calluna vulgaris*) of dune heaths, dune "bushland" or scrub, and dune forest.

8. Chorophytes.—Here are placed certain "xerophytic perennial herbs" which occur on "particular dry kinds of soil, such as limestone," and so forth (Warming, 1900 : 286).

D. The climate is very dry, and the properties of the soil are decided by climate.

9. Xerophytes.—Under this term, are placed plants of deserts and steppes.

10. *Sylocarpus* group.—Here are placed plants found in "savannah-vegetation," viz. (i.) "thorny savannah-vegetation, including: (a) orchard-scrub, (b) thorn-bushland and thorn-forest; (ii.) true savannah: tropical and sub-tropical savannah; (iii.) savannah-forest, including: (a) *Sesleria* and *Oxalis*; and (iv.) "camos sarradens" in Brazil (Warming, 1900 : 293 et seq.).

11. *Sclerophyllous* formations, e.g., garigues, mäquis, and forests of evergreen oaks (Q. Ilex, Q. Ballota, Q. Suber), and of *Eucalyptus* spp.

E. The soil is physically or physiologically dry.

F. Soil and climate favour the development of mesophyllous formations, or of *Angiosperms*.

13. *Mesophytes*.—Warming defines mesophytes as "plants that show a preference for soil and air of moderate humidity, and avoid soil with standing water or containing a great abundance of salts" (Warming, 1900 : 317). Under *mesophytes*, Warming places plants occurring in "soils of the Alps, and Alp-like soils and montane vegetation of the Alps," in meadows, in pasture on cultivated soil, in "mesophytic bushland," in deciduous dicotyledonous forests, and in evergreen dicotyledonous forests.

This new system of Warming's, whilst probably too involved ever to come into general use, must be taken as superseding his older one;2 and perhaps the best course open to botanists is to select such terms as appear to be helpful, and to use the selected terms in a general kind of way and without demanding any precise definitions of them: it must also be borne in mind that the various classes are neither mutually exclusive nor of equivalent rank. From this point of view, the following terms will perhaps be found the most serviceable:

**Hyrophytes** (submerged aquatic plants).—Plants whose vegetative organs live wholly in water; e.g., most Algae, many mosses, various Thallophytes, and *Jania reniformis* spp., a few Pteridophytes, such as *Pilularia spp.*, *Isettes spp.*, several flowering plants, such as *Pontomogeon pectinatus*, *Carpetophyllum ssp.*, *Holotoma palustris*, *Utricularia ssp.*, *Littorella uncinata*.

**Helophytes**.—Plants whose vegetative organs are partly submerged and partly aerial: *Vauceria terrestriis*, *Philomathis fontana*, *Scapania undulata*, *Marisil ssp.*, *Salix alba*, *A. fragilis*, *S. cinerea*, *S. pentandra*, *liriiorda lacustris*.

**Xerophytes**.—Plants which are xerophytes, or evergreen but not sclerophyllous, and which live in moist soils; e.g., *Lasuicae, Pinus palustris*, *Carex ovata*, *Plantago lanceolata*, and *Aegion Millfolium*.

**Heterophytes**.—Plants which live in evergreen leathery leaves, and typical of tropical, sub-tropical, and warm temperate regions; e.g., *Quercus Suber*, *Ilex Aquifolium*, *Hedera Helix*, *Eucalyptus Globulus*, *Rosmarinus officinalis*. Sclerophyllous leaves are usually those of a broad-leaved evergreen, which, though small but rarely sunken stomata, a well-developed and close-set pallese tissue and a feeble system of air-spaces.

**Hydrophytes** ("bog xerophytes").—Plants which live in wet, swampy soils, and which possess aeration channels and xerophyllous leaves; e.g., *Cladium Marisius*, *Errophorum angustifolium*, *Rubus Chamaemorus*, and *Vaccinium Vittis-Idaea*. The term "xero-

**Plant Communities.**—The study of plant communities (Ecologischelehe or synecology) has made much progress in recent years. Even here, however, general agreement has not been reached; and the questions involved in relating the facts of the distribution of plant communities to the factors of the habitat are very imperfectly understood. Plant communities may be classified as follows:

A. A plant association is a community of definite floristic composition, which may be characterized by a single dominant species; or, on the other hand, it may be characterized by a number of prominent species, one of which is abundant here, whilst elsewhere two or more species may share dominance. The former are *pure associations*, and are well illustrated by a heather moor, where *Calluna vulgaris* is the dominant plant. The latter are *mixed associations*, such as fens, where different facies are produced by the varying abundance of characteristic plants, such as *Cladium Marisius*, *Phragmites communis*, *Molinia coerulea*, *Calamagrostis lanceolata*, and *Juncus obtsufolius*. The different facies are possibly related to slight differences in a generally uniform habitat: it is unsatisfactory to regard them as due to chance; still, in the majority of cases, the causes of the different facies have not been demonstrated. A local aggregation of a species other than the dominant one in an association brings about a *plant society*; for example, societies of *Erica Tetralis*, of *Scirpus caspius*, of *Molinia coerulea*, of *Carex curta*, of *Nartheicum autumnale*, and others may occur within an association of *Calluna vulgaris*. The plant societies are also doubtless due to slight variations of the habitat.

The plant association is sometimes referred to in technical language, the termination -*etum* is added to the stem of the generic name, and the specific name is put in the genitive. Thus

1 Warming (1900, op. cit.).

2 Ibid. (1894, op. cit.).
an association of *Quercus sessiliflora* may be referred to as a *Quercetum sessiliflorae*.

A plant formation is a group of associations occupying habitats which are in essentials identical with each other. Thus, associations of *Agropyrum (Triticum) junceum*, of *Carex arenaria*, of *Ammophila (Psamma) arenaria*, and of other plants occur on sand dunes: the associations are related by the general identity of the habitat conditions, namely, the physiological dryness and the loose soil; but they are separated by differences in floristic composition, especially by different dominant species, and by minor differences of the common habitat. The whole set of associations on the sand dunes constitutes a plant formation.

The plant formation may be designated in technical language by the termination -ion added to a term denoting the habitat. Thus, a sand dune formation may be termed an *Arenarion*. The associational term, in the genitive, may be added to the formational term to indicate the relationship of the formation to its association; thus, a plant association of *Ammophila arenaria* belonging to the plant formation of the sand dunes may be designated an *Arenarion Ammophilae-arenariae* (cf. Moss, op. cit. 1910: 43).

The question of universal names for vegetation units is bound up with that of the universality or otherwise of particular formations. "Remote regions which are floristically distinct from each other possess areas physically almost identical and yet be covered by different formations" (Clements, 1905: 203). For example, the sand dunes of North America and those of western Europe are widely separated in geographical position and therefore in floristic composition, yet they are related by common physical factors. This relationship may be indicated by the addition of some prefix to the formational name. For example, an *Arenarion* in one climatic or geographical region might be termed an α-*Arenarion* and one in a different region a β-*Arenarion*, and so on (Moss, loc. cit.).

It is, however, frequently desirable to consider such allied formations as a single group. Such a group of formations may be designated a plant federation: and this term may be defined as a group of formations, which are characterized by common edaphic factors of the habitat, and which occur in any geographical region. Thus, different geographical or climatic regions are characterized by salt marshes. The latter all agree in their edaphic characteristics; but they differ climatically and in floristic composition. The salt marshes of a given region constitute a single plant formation: the salt marsh formations of the whole world constitute a plant federation.

Again, it is possible to arrange plant associations into groups related by a common plant form. Thus woodland associations may be classified as deciduous forests, coniferous forests, sclerophyllous forests, &c. These, in a general way, are the "formations" of Warming, and (in part) the "climatic formations" of Schimper. Thus the various reed-swamps of the whole world constitute a "formation" in Warming's sense (1900: 187).

There is much difference of opinion among ecologists and plant geographers as to which of these points of view is the most fundamental. Among British authorities, it is now customary to adopt the position of Clements, who states (1905: 11) that "the connexion between formation and habitat is so close that any application of the term to a division greater or smaller than the habitat is both illogical and unfortunate," and that (1905: 18) "habitats are inseparable from the formations which they bear" (cf. Moss, loc. cit.).

From the standpoint of plant communities, it is convenient to divide the earth's surface into (1) tropical districts; (2) sub-tropical and warm temperate districts; (3) temperate districts; (4) cold temperate and frigid districts.

1. Tropical Districts. The vegetation of tropical districts has been described (especially in *Eclogae geogr.*, et seq.) as follows:

(i.) Tropical woodland: (a) rain forest, (b) monsoon forest, (c) savanna forest, (d) savanna forest, (e) tropical grassland: (a) *savanna*, (b) steppe. (i) Tropical desert: (a) scrub, (b) succulent plants, (c) perennial herbs.

Other minor divisions as groups of "climatic formations"; and he also distinguishes certain tropical "edaphic formations," such as marangrove swamps. He states that rain forests and high monsoon forests in the tropics occur when the average rainfall is over 76 cm. (178 in.) and low monsoon forest may prevail when the mean annual rainfall is below 35 in.

A tropical rain forest exhibits great variety both of species of plant and of plant forms. There is great diversity in the trees: their habit is usually that of the large-leaved tree, with terminal or sub-terminal flower and fruit clusters, and the heavy leafy forest crown. Humboldt6 points out that whilst tropical forests frequently furnish pure associations, such uniformity of association is usually absent from the tropics. Some tropical forests exhibit dense foliage from the base to the topmost branches and are consequently leaffy and impenetrable. Other tropical forests afford a free passage and a clear outlook. It is obvious that tropical forests will eventually be subdivided into plant associations; but the difficulties of determining the limits of these associations are great. The upper layer of tropical rain and monsoon forests is very great. One of the best known results of the great struggle for light which takes place in tropical forests is the number of epiphytic plants which grow on the high branches of the trees, whilst the lower passage is occupied by a dense mass of lower forms. The seeds of many of the plants in tropical forests are dispersed by the wind and the air current. The seedlings of many of the species of *Rhizophoraceae* germinate on the trees, and probably perform some assimilatory work by means of the hypostrophs.

Other tropical "climatic formations" occur on sandy shores, where the creeping *Ipomoea biloba* (Pescapetrae) and trees of *Barringtonia* form characteristic plant associations.

The succession of associations on new soils of a tropical shore has been investigated by *Eck."* 2. Warm Temperate and Subtropical Districts. In subtropical and warm temperate districts, characterized by mild and rainy winters and hot and dry summers, we find two types of forests.

First, there are forests of evergreen trees, which belong to sclerophyllous forests, and they occur in the Mediterranean region, in south-west Africa, in south and south-west Australia, in central Chile, and in western California. In the Mediterranean district, forests of this type are sometimes dominated by *Pinus sylvestris*, and in the type of vegetation is sometimes by forest of *Quercus ilex*. When these forests become degenerate, maquis and garigues respectively are produced. Mâquis and garigues are characterized by the abundance of shrubs and under-shrubs, especially by shrubby Leguminous plants, and by species of the *Labiatae*. Secondly, there are forests of coniferous trees. In the Mediterranean region, even at comparatively low altitudes, forests occur of the maritime pine (*Pinus maritime*) and of the Aleppo pine (*P. halepensis*); and these forests are also related to maquis and garigue, respectively, by the degeneration of forests of this type in the Mediterranean and in Arctic regions, whose dominant species belong to the same genus (*Pinus*) and to the same plant form, renders it to...
PLANTS

subdivided plant geography into floristic plant geography and ecological plant geography. The former is concerned with the subdivision of the floras of the world into major districts characterized by particular plants or taxonomic groups of plants, with the subdivision of these floristic districts, and with the geographical distribution (both past and present) of the various taxonomic units, such as species, genera, and families. On the other hand, ecological plant geography seeks to ascertain the distribution of plant communities, such as associations and formations, and enquires into the nature of the factors of the habitat which are related to the distribution of plants—plant forms, species, and communities. In a general way, floristic plant geography is concerned with species, ecological plant geography with vegetation. The study of the distribution of species dates back to the time of the early systematists, the study of vegetation to the time of the early botanical travellers. Humboldt, for example, defined his view of the scope of plant geography as follows: 'C'est cette science qui consiè alleged local in the different climates' (1807: 14).

The Habitat.—The term habitat, in its widest sense, includes all the factors of the environment which affect a plant or a plant community, though the term is frequently used to signify only some of these factors. The factors of the habitat may be grouped as follows: geographical, physical, and biological.

Geographical Factors.—Geographical position determines the particular species of plants which grow in any particular locality. This matter is bound up with the centres of origin and with the past migrations of species; and such questions are usually treated as a part of a wider geographical discussion. Thus, for example, Flahault and Schröter, in defining the term habitat, appear to exclude all geographical factors. They state that the term habitat is understood to include everything relating to the plant's origin and development, a definition which is, so far as these factors influence plants (1910: 24); but the exclusion of geographical and historical factors from the concept of the habitat does not appear to be either desirable or logical.

Physical Factors.—These are often classified as edaphic or soil factors and climatic factors; but such a sharp line of demarcation between them is impossible. Edaphic factors include all those relating to the soil. The water content of the soil, its mineral content, its humus content, its temperature, and its physical characteristics, such as depth and size of its component particles, are all edaphic factors. Climatic factors include all those relating to atmospheric temperature, rainfall, atmospheric humidity, and light and shade. Factors connected with altitude, aspect, and exposure, and winds, are also classified as climatic or physical factors. The difficulty of sharply delimiting edaphic and climatic factors is seen in the case of temperature. Soil temperature is partly dependent on the direct rays of the sun, partly on the wind, and partly on the water content of the soil. Again, the temperature of the air is affected by radiation from the soil; and radiation differs in various soils.

Biological Factors.—These include the reactions of plants and animals on the habitat. Here again, no sharp boundary-line can be drawn. In one sense, the accumulation of humus and peat is a biological factor, as it is related to the work of organisms in the soil; and yet, there are other causes which may affect the accumulation of humus and peat in a similar manner, and which are probably related to definite edaphic and climatic conditions. Again, the well-known action of earthworms may be said to be a biological work: but the resulting aerating of the soil causes edaphic differences, and plants and animals of certain soils, such as peat. The pollination of flowers and the dispersal of seeds by various animals are biological factors; but pollination and dispersal by the wind cannot be regarded as the influence of man on plants and vegetation is also a biological factor, which is frequently ignored as such, and treated as if it were a thing of the past.

When the nature and effect of ecological factors have become more fully understood, it will be possible to dispense with the above arbitrary distinction of factors, and to frame one depending on the action of the various factors. Without such a classification it is not possible in the present state of knowledge.

Ecology and Physiology.—Whilst our knowledge of the nature and effect of habitat is still in a very rudimentary condition, much progress has been made in recent years in the study of plant communities; but even here the questions involved in relating the facts of the distribution of plant communities to the factors of the habitat are very imperfectly understood. This is due to a lack of precise knowledge of the various habitat factors and also of the responses made by plants to these factors. Until much more advance has been made by ecologists in the investigation of the nature of habitat factors, and until the effect of the factors on the plants has been more closely investigated by physiologists, it will remain impossible to place ecology on a physiological basis: all that is possible at present is to give a physiological bias to certain aspects of ecological research. Obviously no more than this is possible until physiologists are able to state much more precisely than at present what is the influence of common salt on the plants of salt-marshes, of the action of calcium carbonate on plants of calcareous soils, and of the action of humus compounds on plants of fens and peat moors.

Ecological Classes.—Many attempts have been made to divide plants and plant communities into classes depending on habitat factors. One of the best known classifications on these lines is that by Warming. Warming recognized and defined four ecological classes as follows:

Hydrophytes.—These live in a watery or wet substratum, with at least 80% of water. Warming included plants of peat-bogs among his hydrophytes.

Xerophytes.—These are plants which live in very dry places, where the substratum has less than 10% of water.

Mesophytes.—These are plants which live in localities which are neither specially dry nor specially wet nor specially salty.

Such terms as hydrophytes, xerophytes, and halophytes had been used by plant geographers before Warming's time e.g., by Schouw; and the terms evidently supply a want felt by botanists as they have come to general use. However, the terms are incapable of exact definition, and are only useful when used in a very general way. The above classification by Warming, although it was without doubt the best ecological classification which had, at the time, been put forward, has not escaped criticism. The criticisms were directed chiefly to the inclusion of sand dune plants among halophytes, to the exclusion of halophytes from xerophytes, to the inclusion of 'bog xerophytes' among hydrophytes, to the inclusion of all conifers among xerophytes and of all deciduous trees among mesophytes, and to the group of mesophytes in general.

Schimper made a great advance when he distinguished between physiological and physiological dryness or wetness of the soil. A soil may be physically wet; but if the plants absorb the water only with difficulty, as in a salt marsh, then the soil is, as regards plants, physiologically dry. All soils which are physically dry are also physiologically dry; and hence only the physiological dryness or wetness of soils need be considered in ecology.

Schimper used the term xerophytes to include plants which live in soils which are physiologically dry, and the term hydrophytes those which live in soils which are physiologically wet or damp. Schimper recognized that the two classes are connected by transitional forms, and that it is useless to attempt to give the matter a statistical basis. It is only in a general sense that Schimper's that such ecological terms as xerophytes have any value; and it is not possible, at least at present, to frame ecological classes, which shall have a high scientific value, on a basis of this nature. Whilst Schimper objected to the constitution of a special category, such as 'bog xerophytes', to include all plants which are neither pronounced hydrophytes nor pronounced xerophytes, he recognized the necessity of a third class in which to place these

difficult to regard "coniferous forests" as a natural ecological group. At much higher altitudes, in the south-west of the Mediterranean region, forests occur of the Atlantic cedar (Cedrus atlantica). These occur from about 4000 ft. (1219 m.) to about 7000 ft. (2133 m.) on the Atlas Mountains, and are of a comparatively high rainfall, characterized by many deciduous trees, such as Fraxinus oxyphylla, Ulmus campestris (auct. alg.), Alnus rotundifolia, Salix pedunculata, &c.; and have some elements in common with the deciduous forests of central Europe. The forests of these subtropical and warm temperate regions are situated near the sea or in mountainous regions, and (as already stated) are often accompanied by wet grasslands. In some, the rainfall is much lower, and steppes occur. For example, in southern Algeria, a region of steppes is situated on a flat plateau, about 3000 ft. (914 metres) high, between the southern slopes of the Tassili Mountains and the Tell. The rainfall, which occurs chiefly in winter, only averages about 10 in. (254 mm.) per annum. Here we find open plant associations of Halla or Esparto Grass (Stipa lessinissma) alternating with steppe Chih (Artemisia herba-alba); and each plant association extends for several scores of miles. In the hollows of this steppe region, salt water lakes occur, known as Chotts; and on the saline roundings the Chotts, a salt marsh formation occurs, with species of Salicornia, some of which are undershrubs. The moisture is supplied by seepage. About 41/2 in. (114 mm.) in 1890, it fell as low as 2 in. (53 mm.) (Schimper, 1903 p. 606). At Benz Oumil and Colomb Bédéch, in north-eastern Algeria, it is stated that there had been no rain for about three years. Here the gravelly soil is characterized by "cushion plants," such as Anabasis ariodosus; by "switch plants," such as Retama Retam; and especially by "stunted plants," Zygophyllum dumosum, &c.; whereas succulent plants are rare. Both in the steppe and in the desert, small ephemeral species occur on the bare ground away from the large plants and especially in the wadis. Steppes and desert vegetation are characteristic of the desert region.

3. Temperate Districts.—Temperate districts are characterized by forests of deciduous trees and of coniferous trees, the latter being of different species from those of the warm temperate districts, but similar to those of the cold temperate districts. The former are characterized by the paucity of many of the conifers of both temperate and of warm temperate districts, whereas succulent plants are rare. Both in the steppe and in the desert, small ephemeral species occur on the bare ground away from the large plants and especially in the wadis. Steppes and desert vegetation are characteristic of the desert region.

4. Cold Temperate and Frigid Districts.—In the coldest portion of the north temperate zone, forests of dwarfed trees occur, and these occasionally spread into the Arctic region. In the northern parts of Sweden 1900 (685). Schimper distinguishes moss tundra, Polytrichum tundra, and lichen tundra; and the lichen tundra is subdivided into Cladonia tundra, Platysma tundra, and Alectoria tundra. Where the climate is most rigorous, rock tundra occurs (p. 685).

The types of vegetation (tropical forests, sclerophyllous forest, temperate forests, tundra, &c.) thus briefly outlined are groups of Schimper’s "climatic formations." Such groups are intergrading in the tropics, and there is a broad sense, related more to climatic than to edaphic conditions. For example, Schimper, after describing the sclerophyllous woodland of the Mediterranean district and of the Cape district, says: "The scrub of West and South Australia in its ecological aspect resembles so completely the other sclerophyllous formations that a description of it must seem a repetition." This resemblance, however, only has reference to the general aspect or physiognomy of the vegetation and to the plant forms: the floristic composition of the various sclerophyllous—and other physiognomically allied—associations in the various geographical districts is very different; and indeed it is true that, just as the general physiognomy of plant associations is related to climate, so their floristic composition is related to geographical position. Hence, in any cosmopolitan treatment of vegetation, it is necessary to consider the groups of plant communities from the standpoint of the climatic or geographical district in which they occur; and this

plants under such conditions become smaller and more succulent. He showed further, that the increase of common salt in the soil is correlated with a reduction in the number and size of the chloroplasts, and therefore in the amount of chlorophyll. On the other hand, the growth of certain halophytes depends on the presence of salt, whilst others were killed. Warming (1909: 220) quotes Grignon (1868), to the effect that "the assimilatory activity is less in the halophytic form than in the ordinary form of the same species."

The presence of salt in the soil is not detrimental as regards assimilation. Many marine Algae appear to be able to regulate their osmotic capacity to the surrounding medium; and T. G. Hill has shown that the root-hairs of Sagittaria possess this property. There has however been performed upon halophytes very little physiologically experimental work which commands general acceptance.

Bog Xerophytes live in the peaty soil of fens and moors which are poorly aerated by the waterlogged state of the soil. In addition to the physiological drought, such plants possess some xerophytic characters and, related to the physical wetness, the plants possess the aeration channels which characterize many hydrophytes and hemi-hydr phytes. Bog Xerophytes of this type have given rise to much disagreement of opinion. It is sometimes maintained, for example, by Schimper, that their xerophytic characters are related to the physiological dryness of the habitat. It is however, is oxidized or biogenous in origin; and many plants of this type have given rise to much disagreement of opinion. It is sometimes maintained, for example, by Schimper, that their xerophytic characters are related to the physiological dryness of the habitat. It is however, maintained, that the xerophytes are due to the persistence of ancestral structures. It is possible, of course, that each explanation is correct in particular cases, as the views are by no means mutually exclusive. However, the xerophytes are characterized by the presence of some xerophytic organs, such as Juncus effusus, which possess xerophytic characters and yet live in situations which are not necessarily marked by physiologically dryness. It should be remembered that such habitats are likely to be subject to other physical conditions, and a plant must eventually succumb if it is not competent to adapt itself to the habitat.

Xerophytes-These plants are characterized by being xerophytic during the unfavourable season. For example, deciduous trees shed their leaves in winter; geophytes go through a period of dormancy. However, the xerophytes are an organ of the plant, and the leaves are placed edge-wise to the incident rays of light and heat. The xerophytes, or "sclerophyllous plants" also, to some extent, are similarly protective. In such leaves, there is a high degree of lignification in xerophytes, and at least on the upper side of the leaf, well-developed palisade tissue, and a poorly developed system of air-spaces. Such adaptations are well seen in the leaf of the holly (Ilex aquifolium). Warming, however, states that "Ilex aquifolium is undoubtedly a mesophyte (1909: 135)."

Halophytes, or plants which live in saline soils, have xerophytic adaptations. A considerable proportion of halophytes are succulent, and their occurrence is related to the occurrence of some water-storing tissue and few intercellular spaces. Some halophytes tend to lose their succulence when cultivated in a non-saline soil; and some non-succulent halophytes tend to become succulent when cultivated in a saline soil. The xerophytes are maintained by the leaves being thick, with a high content of water. Xerophytes are relatively small, and their xerophytic characters are related to the same circumstance. Forms of "stone cells" or "sclereids" occur in some of the more succulent halophytes in Asphragnum glaucum. The interesting occurrence of certain halophytes is that the occurrence of succulent halophytes, and the occurrence of some xerophytic characters, are related to the same circumstance. The effect of common salt on the establishment of plants is not understood. Lesage has shown that the height of certain plants is decreased by cultivation in a saline soil, and that the leaves of plants under such conditions become smaller and more succulent. He showed further, that the increase of common salt in the soil is correlated with a reduction in the number and size of the chloroplasts, and therefore in the amount of chlorophyll. On the other hand, the growth of certain halophytes depends on the presence of salt, whilst others were killed. Warming (1909: 220) quotes Grignon (1868), to the effect that "the assimilatory activity is less in the halophytic form than in the ordinary form of the same species."

The presence of salt in the soil is not detrimental as regards assimilation. Many marine Algae appear to be able to regulate their osmotic capacity to the surrounding medium; and T. G. CYTOLOGY

PLANTS

scoparia, Potentilla procumbens, Galium hercynicum (= G. satiaticum), Gnaphalium syriacum, Digitalis purpurea. Other plants occur indiscriminately both on calcareous and on non-calcareous soils.

It is sometimes said that lime acts as a poison on some plants and as a fertilizer on others, and sometimes the (1900) biologist-thinking of calcareous soils that is the important factor, in relation to the latter theory, it is pointed out that some markedly calcicoles species occur on sand dune; but this may be due to the lime which is frequently present in dune sand as well as to the physical dryness of the soil. Further, no theory of calcioles and calcifuges plants can be regarded as satisfactory which fails to account for the fact that both kinds of plants occur aquatic as well as among terrestrial, and some may even be very poorly calcified. In the case of aquatic plants, the difference must depend on the amount of lime in the water, for the physical nature of the substrate is the same in each case. Again, acidic humus does not form the preparation of terrestrial plants, and it is also true that terrestrial plants characteristic of acidic poor or humus on calcareous soils. Some such species are Blechnum boreale, Atra flexuosa, Calluna vulgaris, Vaccinium, Myrtillus, Rubus, Chamaemorus, Empetrum nigrum, Dracaena spp. Some, at least, of these species possess microhiza in their roots, and are perhaps unable to live in soils where such organisms are absent.

In England, the number of calcicoles species greater than the number of silicious species. It would therefore be curious if it were proved that lime affects on plants as a poison. It is said that some plants may be calcicoles in one geographical district and not in another. However, until more is known of the exact chemical composition of the lime, it is not possible to decide the vexed question of the relation of lime-loving and lime-shunning plants to the presence or absence of calcium carbonate in the soil. From such points of view as this, it is the opinion of the author that liming has recently started, "the theory is only in its infancy." (C. E. M.)

CYTOLOGY OF PLANTS.

The elementary unit of plant structure, as of animal structure, is the cell. Within it or its modifications the vital phenomena of which living organisms are capable have their origin. Upon our knowledge of its minute structure or cytology, combined with a study of its physiological activities, depends the ultimate solution of all the important problems of nutrition and growth, reception and conduction of stimuli, heredity, variation, sex and reproduction.

The Cell Theory.—For a general and historical account of the cell theory see CYTOLOGY. It is sufficient to note here that cells were first of all discovered in various vegetable tissues by Robert Hooke in 1665 (Micrographia); Malpighi and Grew (1674–1682) gave the first clear recognition of the independence of the cells in plant tissues, but it was not until the beginning of the 19th century that any insight into the real nature of the cell and its functions was obtained. Hugo von Mohl (1836) was the first to recognize that the essential constituent of the cell is the cytoplasm—inside it, and not the cell wall as was formerly supposed. The nucleus was definitely recognized in the plant cell by Robert Brown in 1831, but its presence had been previously indicated by various observers and it had been seen by Fontana in some animal cells as early as 1781. The cell theory so far as it relates to plants was established by Schleiden in 1838. He showed that all the organs of plants are built up of cells, that the plant embryo originates from a single cell, and that the physiological activities of the plant are dependent upon the individual activities of these vital units. This conception of the plant as an aggregate or colony of independent vital units governing the nutrition, growth and reproduction of the whole plant was based upon the knowledge that the unicellular plants all the vital activities are performed by a single cell, but in the multicellular plants there is a more or less highly developed differentiation of physiological activity giving rise to different tissues or organs such as leaves, roots, stems, and flowers. The cell in such a division of labour cannot therefore be regarded as an independent unit. It is an integral part of an individual organization and as such the exercise of its functions must be governed by the organism as a whole.

General Structure and Differentiation of the Vegetable Cell.—The simplest cell form are found in embryonic tissues, in reproductive cells and in the parenchymatous cells, found in various parts of the plant. The epidermal, conducting and strengthening tissues show on the other hand considerable modifications both in form and structure.

The protoplasm of a living cell consists of a semifluid granular substance, called the cytoplasm, one or more nuclei, and sometimes centrosomes and plastids. Cells from different parts of a plant differ very much in their cell-contents. Young cells are full of cytoplasm, old cells generally contain a large vacuole or vacuoles, containing cell-sap, and with only a thin, almost invisible layer of cytoplasm on their walls. Chlorophyll grains, chromatophores, starch-grains and oil-globules, all of which can be distinguished either by their appearance or by chemical reagents, may also be present. Very little is known of the finer structure of the cytoplasm of a vegetable cell. It is sometimes differentiated into a clearer outer layer, of hyaloplasm, commonly called the cytoplasm, and an inner granular endoplasm. In some cases it shows, when submitted to a careful examination under the highest powers of the microscope, and especially when treated with reagents of various kinds, traces of a more or less definite structure in the form of a meshwork consisting of a clear homogeneous substance containing numerous minute bodies known as microsomes, the spaces being filled by a more fluid ground-substance. This structure, which is visible both in living cells and in cells treated by reagents, has been interpreted by many observers as a network of threads embedded in a homogeneous ground-substance. Bützchi, on the other hand, interprets it as a finely vacuolated foamy-structure or emulsion, comparable to that which is observed when small drops of a mixture of finely powdered potash and oil are placed in water, the vacuoles or alveoli being spaces filled with liquid, the more solid portion representing the mesh-work in which the microsomes are placed. Evidence is not wanting, however, that the cytoplasm must be regarded as, fundamentally, a semifluid, homogeneous substance in which by its own activity, granules, vacuoles, fibrils, &c., can be formed as secondary structures. The cytoplasm is largely concerned in the formation of spindle fibres and centrosomes, and such structures as the cell membrane, cilia, or flagella, the coenocentrum, nematoplasts or vibrioids and physeses are also products of its activity.

Protoplasmic Movements.—In the cells of many plants the cytoplasm frequently exhibits movements of circulation or rotation. The cells of the staminal hairs of Tradescantia virginica contain a large sap-cavity across which run, in all directions, numerous protoplasmic threads or bridges. In these, under favourable conditions, streaming movements of the cytoplasm in various directions can be observed. In other forms such as Elodea, Nitella, Chara, &c., where the cytoplasm is mainly restricted to the periphery of the sap vacule and lining the cell wall, the streaming movement is exhibited in one direction only. In some cases both the nucleus and the chromatophores may be carried along in the rotating stream, but in others, such as Nitella, the chloroplasts may remain motionless in a non-motive layer of the cytoplasm in direct contact with the cell wall.

Desmidia, Diatoms and Oscillatoria show creeping movements probably due to the secretion of slime by the cells; the spores branches and plasmoidium of the Myxomycetes exhibit amoeboid movements; and the motile spores of Fungi and Algae, the spermatozoids of mosses, ferns, &c., move by means of delicate prolongations, cilia or flagella of the protoplasm.

Chromatophores.—The chromatophores or plastids are protoplasmic structures, denser than the cytoplasm, and easily distinguished from it by their colour of greater refractivity. They are spherical, oval, fusiform, or rod-like, and are always found in the cytoplasm, never in the cell-sap. They appear to be permanent organs of the cell, and are transmitted from one cell to another by division. In young cells the chromatophores are small, colourless, highly refractive bodies, principally located around the nucleus. As the cell grows they may become converted into leucoplasts (starch-formers), chloroplasts (chlorophyll-bodies), or chromoplasts (colour-bodies). And all three structures may be converted one into the other (Schimper). The chloroplasts are generally distinguished by their green colour, which is due to the presence of chlorophyll, but in many algae this is masked by another colouring matter—Phycocerythrin in the Florideae, Phycocyanin in the Phaeocystis, and Phycoplatin in the Phaeophyceae.
in the Cyanophyceae. These substances can, however, be dissolved out in water, and the green colouring matter of the chloroplast then becomes visible. The chloroplast consists of two parts, a colourless ground substance, and a green colouring matter, which is contained either in the form of fibrils, or in more or less regular spherical masses, in the colourless ground-mass. The chloroplasts increase in number by division, which takes place in higher plants when they have attained a certain size, independent of the division of the cell. In Spirophyta and allied forms the chloroplast grows as the cell grows, and only divides when this divides. The division in all cases takes place by con- striction, or by a simultaneous splitting along an equatorial plane. Chloroplasts are very sensitive to light and are capable in some plants of changing their position in the cell under the stimulus of a variation in the intensity of the light rays which fall upon them.

In the chromatophores of many Algae and in the Liverwort Anthoceros there are present homogeneous, highly refractive, crystal-like bodies, called Chromatophores, which are composed of proteid substances and surrounded by an envelope of starch-grains. In Spirophyta the pyridoids are distinctly connected by cytoplasmic strands to the central mass of cytoplasm, which surrounds the nucleus, and according to some observers, they increase exclusively by division, followed by a splitting of the cytoplasmic strands. Those chromatophores which remain colourless, and serve simply as starch-formers in parts of the plant not exposed to the light, are called leucoplasts or amyloplasts. They are composed of a homogeneous proteid substance, and often contain albuminoid or proteid crystals of the same kind as those which form the pyridoids. If exposed to light they may become converted into chloroplasts. The formation of starch may take place in any part of the leucoplast. When formed inside it, the starch-grains exhibit a concentric arrangement; when formed externally in the outer layers, the strati- fication becomes excentric, and the hilum occurs on that side farther removed from the leucoplast. As the starch-grains grow, the leucoplasts gradually disappear.

Chromoplasts are the yellow, orange or red colour-bodies found in some flowers and fruits. They arise either from the leucoplasts or chloroplasts. The fundamental substance or stroma is always homogeneous and colourless. The colour is due to the presence of xanthophyll, or to haematoporphyrin, or to carotin or both. The colouring matters are not dissolved in the stroma of the chloroplast, but exist as amorphous granules, with or without the presence of the leucoplast. Their shape is usually fine and acicular, and sometimes present in large numbers, which are grouped together in various ways in bundles and give the plastids their fusiform or triangular crystalline shape. Such crystalline plastids are observed in various parts of the plant, e.g., in the stems of Cucurbita, or in the young leaves of Triticum, Equisetum, Asparagus, Lonicerâ, berries of Solanaceae, flowers of Cacalia, cocoa, Yuccidium, bracts of Streptis, etc., and in the root of the carrot. In some cases the plastids disappear, and the crystalline pigment only is left. In the red variety of Cucurbita pepo, Sphagneticum, the nucleus of the cell may consist of rods, thin plates, flat ribbons or spirals. Starch grains may often be seen in contact with the pigment crystals. The crystalline form appears to be due entirely to the carotin, which can be dissolved out of the pigment without the other solution. In addition to the plastids, there are found in some plant-cells, e.g., in the epidermal cells of the leaf of species of Vanilla (Wakker), and in the epidermis of different parts of the flower of Forsythia (Engelmann), in some cases by the occurrence of globular form, elaioplast, which consists of a granular protein ground-substance containing drops of oil. They are stained deep red in dilute solution of alkali.

Substances contained in the Protoplast.—Starch may be found in the chlorophyll bodies in the form of minute granules as the first visible product of the assimilation of carbon dioxide, and it occurs in large quantities as a reserve food material in the cells of various parts of plants. It is highly probable that starch is only produced as the result of the activity of chromatophores, either in connection with chloroplasts, chloroplasts or leucoplasts. Starch exists, in the majority of cases, in the form of granules, which are composed of stratified layers arranged around a nucleus or hilum. The stratification, which may be concentric or excentric, appears to be due to a difference in density of the various layers. The outer layers are denser than the inner, the density decreasing more or less uniformly from the outside layers to the centre of the hilum. The outermost, newly formed layer is composed of a more homogeneous, denser substance than the inner one, and can be distinguished in all starch-grains that are in process of development. The separate layers of the starch-grain are deposited on it by the activity of the chromatophore, and according to Meyer the grain is always surrounded by a thin layer of the chromatophore which completely separates it from the cytoplasm. The layers appear to be made up of elements which are arranged radially. These are, according to Meyer, acicular crystals, which he calls trichites. The starch grain may thus be regarded as a crystalline structure of the nature of a sphere-crystal, as has been suggested by many observers.

Whether the formation of the starch grain is due to a secretion from the plastid (Meyer, 1895) or to a direct transformation of the protoplasm (Timberlake, 1901) has not been definitely established.

Aleurone—Aleuone is a proteid substance which occurs in seeds especially those containing oil, in the form of minute granules or large grains. It may be in the form of an amorphous crystal sometimes associated with a more or less spherical body—globoid—composed of a combination of an organic substance with a double phosphates of magnesium and calcium. Aleurone crystals are also to be found in the cytoplasm, in leucoplasts and rarely in the nucleus.

Volatiles—A volatile substance is found in the cytoplasm, e.g., in the cytoplasm of Fungi, Cyanophyceae, diatoms, etc., in the form of minute granules which have a characteristic reaction towards methylene blue (Meyer). It has been suggested that some of the cytoplasmic bodies, which according to Meyer may be a combination of nucleic acid with an unknown organic base.

Numerous other substances are also found in the cytoplasm, such as tanins, fats and oil, resins, mucilage, catinaceous, gutta-percha, sulphur and calcium oxalate crystals. The cell sap contains various substances in solution such as sugars, inulin, alkaloids, glucosides, organic acids and various inorganic salts. The colours of the cytoplasm are due to colouring matters contained in the sap of which the chief is anthocyanin.

Reference must also be made here to the enzymes or unorganized ferments which occur so largely in the cytoplasm. It is probable that most, if not all, the metabolic changes which take place in a cell, such as the transformation of starch, proteins, sugar, cellulose; and the decomposition of numerous other organic substances which would otherwise require a high temperature or powerful reagents are also due to their activity. Their mode of action is similar to that of ordinary mechanical catalytic agents, such as finely divided platinum (see Bayliss, The Nature of Enzyme Action, and J. R. Green, The Soluble Ferments).

Nucleus.—The nucleus has been demonstrated in all plants, with the exception of the Cyanophyceae and Bacteria, and even here structures have been observed which resemble nuclei in some of their characteristics. The nucleus is regarded as a controlling centre of cell-activity, upon which the growth and development of the cell in large measure depends, and as the agent by which the transmission of specific qualities from one generation to another is brought about. If it is absent, the cell loses its power of assimilation and growth, and soon dies. Haberlandt has shown that in plant cells, when any new formation of membrane is to take place in a given spot, the nucleus is found in its immediate vicinity; and Klebs found that only that portion of the protoplasm of a cell which contains the nucleus is capable of forming a cell-wall; whilst Townsend has further shown that if the non-nucleated mass is connected by strands of protoplasm to a nucleated mass, either of the same cell or of a neighbouring cell, it retains the power of forming a cell-membrane.

The Structure of the Nucleus.—In the living condition the rest- ing nucleus appears to consist of a homogeneous ground sub- stance containing a large number of small chromatin granules and one or more large spherical granules—nucleolii—the whole being surrounded by a limiting membrane which separates it from the cytoplasm. When fixed and stained this granular mass is resolved into a more or less distinct granular network which consists of a substance called Linin, only slightly stained by the ordinary nuclear stains, and, embedded in it, a more deeply staining substance called Chromatin. The nucleolus appears to form a part of the Linin network, but has usually also a strong affinity for nuclear stains. The staining reactions of the various
parts of the nucleus depend to some extent upon their chemical constitution. The chromatin is practically identical with nuclein. This has a strong attraction for basic aniline dyes, and can usually be distinguished from other parts of the cell which are more easily coloured by acid anilines. But the staining reactions of nuclei may vary at different stages of their development; and it is probable that there is no method of staining which differentiates with certainty the various morphological constituents of the nucleus.

Our knowledge of the chemical constitutions of the nucleus is due to the pioneer researches of Sir Lander Brunton, Plow, Miescher, Kossel and a host of more recent investigators. Nuclein is a complex fibrous substance containing phosphorous and iron in a combined form (Macallum). It appears to be a combination of a protein with nucleic acid. Recent researches have shown that the nucleic acid can be broken up by chemical means into a number of different compounds or bases. The results at first obtained were very confusing and seemed to show that nucleic acid is very variable in constitution, but thanks to the work of Schmiedeberg and Stendel (Germany), Ivar Bang (Sweden) and Walter Jones and Levene (America), the confusion has been reduced to some sort of order, and it now seems probable that all ordinary nucleic acids yield two purine bases, adenine and guanine; two pyrimidine bases, cytosine and thymine and a hexose carbohydrate, the identity of which is uncertain.  

The Nuclear.—In the majority of plant-nuclei, both in the higher and lower plants, there is found, in addition to the chromatin network, a deeply stained spherical or slightly irregular body (sometimes more than one) called the nucleolus (fig. 2, A to D). It is often vacular, sometimes granular, and in other cases it is a homogeneous body with no visible structure or differentiation. The special function of this organ has been a source of controversy during the past few years, and much uncertainty still exists as to its true nature. It forms a part of the linin or plastin network of the nucleus and may become impregnated with varying quantities of chromatin stored up for use in the formation of the chromosomes and other nuclear activities. The relation of the nucleolus to the chromosomes is clearly seen in the reconstruction of the daughter nuclei after division in the cells of the root-apex of Phaseolus (fig. 1, A to F). The chromosomes (fig. 1, A) unite to form an irregular mass (fig. 1, B) out of which the nucleolus and nuclear network (figs. 1, E, F) by a fusion of the chromosomes (fig. 1, C, D).

Centrosome.—The centrosome is a minute homogeneous granule found in the cytoplasm of some cells in the neighbourhood of the nucleus. It is generally surrounded by a granular or radiating cytoplasmic substance. In plant cells its presence has been demonstrated in the Thallophytes and Bryophytes. In the higher plants the structures which have been often described as centrosomes are too indefinite in their constitution to allow of this interpretation being placed upon them, and many of them are probably nothing more than granules of the fragmented nucleolus. The centrosomes in plants do not appear to be permanent organs of the cell. They are prominent during cell-division, but may disappear in the resting stage. They are more easily seen, when the nucleus is about to undergo mitosis, at the ends of the spindle, where they form the centres towards which the dividing fibres in the cytoplasm converge (see figs. 7, E, G). The centrosome or centriolium is usually regarded as the dynamic centre of the cell and a special organ of division; but its absence in many groups of plants does not lend support to this view so far as plant-cells are concerned.

Nuclear Division.—The formation of new cells is, in the case of unineucleate cells, preceded by or accompanied by the division of the nucleus. In multinucleate cells the division of the nucleus is independent of the division of the cell. Nuclear division may be indirect or direct, that is to say it may either be accompanied by a series of complicated changes in the nuclear structures called mitosis or karyokinesis (fig. 2), or it may take place by simple direct division, amitosis, or fragmentation. Direct division is a much less common phenomenon than was formerly supposed to be the case. It occurs most frequently in old cells, or in cells which are placed under abnormal conditions.

---

**FIG. 1.—Reconstruction of the daughter nuclei of Phaseolus.**

**Trophoconta;** and in various other cells which have lost their power of division. It has been shown that, in cells of Spirogyra placed under special conditions, amitotic division can be induced, and that normal mitosis is resumed when they are placed again under normal conditions. Amitosis is probably connected by a series of intermediate gradations with karyokinesis.

**Mitosis.**—In indirect nuclear division the nucleus undergoes a series of complicated changes, which result in an equal division of the chromatic substance between the two daughter nuclei. Four stages can be recognized. (1) **Prophase.**—The nucleus increases in size; the network disappears, and a much convoluted thread takes its place (fig. 2, B). The chromatin substance increases in amount; the thread stains more deeply, and in most cases presents a homogeneous appearance. This is commonly called the spirem-figure. The chromatin thread next becomes shorter and thicker, the nucleoli begin to disappear, and the thread breaks up into a number of segments—chromosomes—which vary in number in different species, but are fairly constant in the same species (fig. 2, C, D). Coincident with these changes the nuclear membrane disappears and a spindle-shaped or barrel-shaped group of threads makes its appearance in the midst of the chromosomes, the longitudinal axis of which is at right angles to the plane of the division (fig. 2, F). At each pole of this spindle figure there often occur fibres radiating in all directions into the cytoplasm, and sometimes a minute granular body, the centrosome, is also found there. (2) **Metaphase.**—The chromosomes pass to the equator of the spindle and become attached to the
spindle-fibres in such a way that they form a radiating star-shaped figure—Aster—when seen from the pole of the spindle. This is called the nuclear plate (fig. 2, E, F, G, H). As they pass into this position they undergo a longitudinal splitting by which the chromatins in each chromosome becomes divided into equal halves. (3) Anaphase.—The longitudinal division of the chromosomes is completed by the time they have taken up their position in the nuclear plate, and the halves of the chromosomes then begin to move along the spindle-fibres to opposite poles of the spindle (fig. 2, I, J). Many observers hold the view that the chromosomes are pulled apart by the contraction of the fibres to which they are attached. (4) Telophase.—When they reach the poles the chromosomes group themselves again in the form of stars—Disaster—with spindle-fibres extending between them (fig. 2, K). The chromosomes then fuse together again to form a single thread (fig. 2, L), a nucleolus appears, a nuclear membrane is formed, and daughter nuclei are thus constituted which possess the same structure and staining reactions as the mother nucleus.

The spindle figure is probably the expression of forces which are set up in the cell for the purpose of causing the separation of the daughter chromosomes. Hartog has endeavoured to show that it can be accounted for by a dual force, analogous to that of magnetism, the spindle-fibres being comparable to the lines of force in a magnetic field and possibly due to electrical differences in the cell. The spindle arises partly from the cytoplasm, partly from the nucleus, or at least derived entirely from the nucleus—intranuclear spindle—as occurs in many of the lower plants (Fungi, &c.). The formation of the spindle begins in the prophase of division. A layer of delicate filamentous cytoplasm—kinoplasm—may collect around the nucleus, or another out of which the spindle is formed. As division proceeds, the filamentous nature of this cytoplasm becomes more prominent and the threads begin either to converge towards the poles of the nucleus, to form a bipolar spindle, or may converge towards the surface of the nucleus, to form a multi-polar spindle. The wall of the nucleus breaks down, and the cytoplasmic spindle-fibres become mixed with those derived from the nuclear network. The formation of the spindle differs in details in different plants.

The significance of this complex series of changes is very largely hypothetical. It is clear, however, that an equal quantitative division and distribution of the chromatins to the daughter cells is brought about; and if, as has been suggested, the chromatins consists of minute particles or units which are the carriers of the hereditary characteristics, the nuclear division also probably results in the equal division and distribution of one half of each of these units to each daughter cell.

Reduction Divisions (Meiosis).—The divisions which take place leading to the formation of the sexual cells show a reduction in the number of chromosomes to one-half. This is a necessary consequence of the fusion of two nuclei in fertilization, unless the chromosomes are to be doubled at each generation. In the vascular cryptogams and phanerogams it takes place in the spermo mother cells and the reduced number is found in all the cells of the gametophyte, the full number in those of the sporophyte. We know very little of the details of reduction in the lower plants, but it probably occurs at some stage in the life history of all plants in which sexual nuclear fusion takes place. The reduction is brought about simply by the segmentation of the spermid thread into half the number of segments instead of the normal number. In order to effect this the individual chromosomes must become associated in some way, for there is no diminution in the actual amount of nuclear substance, and this leads to certain modifications in the division which are not seen in the vegetative nuclei. The two divisions of the spore mother cell in which the reduction takes place, follow each other very rapidly and are known as Heterotype and Homotype (Flemming), or according to the terminology of Farmer and Moore (1903) as the meiotic phase. In the heterotype division the spirem thread is divided longitudinally before the segmentation occurs (fig. 2, B), and this is preceded by a peculiar contraction of the thread around the nucleolus which has been termed synopsis (fig. 1, A). A second contraction may take place later, immediately preceding the segmentation of the thread. It has been suggested that synopsis may be connected with the early longitudinal splitting of the thread or with the pairing of the chromosomes, but it is possible that it may be connected with the transference of nucleolar substance to the nuclear thread. The segments of each chromosome are usually twisted upon each other and may be much contorted (fig. 2, C, D), and appearances are observed which suggest a second longitudinal division, but which are more probably due to a folding of the segment by which the two halves come to lie more or less parallel to each other, and form variously shaped figures of greater or less regularity (fig. 2, E). The chromosomes now become attached to the spindle-fibres (fig. 2, F, G) and as the daughter chromosomes become pulled asunder they often appear more or less V-shaped so that each pair appears as a closed ring of irregular shape, the ends of the V's being in contact thus—<> (fig. 2, H, I, J, K). This V has been variously interpreted. Some observers consider that it represents a longitudinal half of the original segment of the spireme, others that it is a half of the segment produced by transverse division by means of which a true qualitative separation of the chromatin is brought about. The problem is a very difficult one and cannot be regarded as definitely settled, but it is difficult to understand why all this additional complexity in the division of the nucleus should be necessary if the final result is only a quantitative separation of the chromatin. It seems to be fairly well established that in the meiotic phase there is a true qualitative division brought about by the pairing of the chromosomes during synopsis, and the subsequent separation of whole...
There chromosomes to the daughter nuclei. The method by which this is brought about is, however, the subject of much controversy. There are two main theories: (1) that the chromosomes which finally separate are at first paired side by side (Allen, Grégoire, Berghs, Strasburger and others), and (2) that they are joined together or paired end to end (Farmer and Moore, Gregory, Mottier and others). Good cytological evidence has been advanced in favour of both theories, but further investigation is necessary before any definite conclusion can be arrived at. The second or homotype division which immediately follows reverts to the normal type except that the already split chromosomes at once separate to form the daughter nuclei without the intervention of a resting stage.

Cell Division.—With the exception of a few plants among the Thallophytes, which consist of a single multinucleate cell, Caulerpä, Vaucheria, &c., the division of the nucleus is followed by the division of the cell either at once, in uninucleate cells, or after a certain number of nuclear divisions, in multinucleate cells. This may take place in various ways. In the higher plants, after the separation of the daughter nuclei, minute granular swellings appear in the equatorial region, on the concave sides of which the daughter nuclei are forced, and so form what is called the cell-plate. These fuse together to form a membrane (fig. 1, C, D) which splits into two layers between which the new cell-wall is laid down. In the Thallophytes the cytoplasm may be segmented by constriction, due to the in-growth of a new cell wall from the old one, as in Spirogyra and Cladophora, or by the formation of cleavage furrows in which the new cell-wall is secreted, as occurs in the formation of the spores in many Algae and Fungi. Cell budding takes place in yeast and in the formation of the conidia of Fungi.

In a few cases both among the higher and the lower plants, of which the formation of spores in the ascus is a typical example, new cells are formed by the aggregation of portions of the cytoplasm around the nuclei which become delimited from the rest of the cell contents by a membrane. This is known as free cell formation.

In Fucus and allied forms the spindle-fibres between the daughter nuclei disappear early and the new cell-wall is formed in the cytoplasm.

Cell Membrane.—The membrane which surrounds the protoplasts in the majority of plants is typically composed of cellulose, together with a number of other substances which are known as pectic compounds. Some of these have a neutral reaction, others react as feeble acids. They can be distinguished by their insolubility in cuprammonia, which dissolves cellulose, and by their behaviour towards stains, some of which stain pectic substances but not cellulose. Cellulose has an affinity for acid stains and is used as substituents for basic stains. The cell-membrane may become modified by the process of lignification, suberization, cuticularization or gelatinization. In the Fungi it is usually composed of a modified form of cellulose known as fungus cellulose, which, according to Mangin, consists of cellulose in combination either with cellulose or pectic compounds. The growth of the cell-wall takes place by the addition of new layers to those already formed. These layers are secreted by the protoplast by the direct apposition of substances on those already in existence; and they may go on increasing in thickness, both by apposition and by the intussusception of particles probably carried in through the protoplasmic fibres, which penetrate the cell-wall as long as the cell lives. The growth of the cell-wall is very rarely uniform. It is thickened more in some places than in others, the thickest parts being at an equatorial, annular and other markings, as well as the pits which occur on various cells and vessels. Besides the internal or centripetal growth, some cell-walls are thickened on the outside, such as pollen grains, oospores of Fungi, cells of Peridiniæ, &c. This centripetal growth must apparently take place by the activity of protoplasm external to the cell. The outer protective walls of the oospores of some Fungi are formed out of protoplasm containing numerous nuclei, which is at an early stage separated from the protoplasm of the oospore. In the Peridiniæ,

**Diatoms and Desmids**, according to recent researches, the thickenings on the outer walls of the cells are due to the passage of protoplasm from the interior of the cell to the outside, through pores which are found perforating the wall on all sides.

Cell-walls may become modified by the impregnation of various substances. Woody or lignified cell-walls appear to contain substances called *conglutins* and *amellin*, in addition to various other compounds which are imperfectly known. Lignified tissues are coloured yellow by aniline sulphate or aniline chloride, violet with phloroglucin and hydrochloric acid, and characteristic reactions are given by mixtures containing phenol, indol, skoal, thallin, sulphate, &c. (see Zimmermann’s *Microtechnic*). Staining reagents can also be used to differentiate lignified cell-walls. Cuticularized or suberized cell-walls occur especially in those cells which perform protective functions. They are impermeable to water and gases. Both cuticularized and suberized membranes are insoluble in cuprammonia, and are coloured yellow or brown in a solution of chloro-iodide of zinc. It is probable that the corky or suberized cells do not contain any cellulose (Gibson, Wisselius); whilst cuticularized cells are only modified in their outer layers, cellulose inner layers being still recognizable. The suberized and cuticularized cell-walls appear to contain a fatty body called suberin, and such cell-walls can be stained red by a solution of alanin, the lignified and cellulose membranes remaining unstained.

**Fertilization.**—The formation of the zygote or egg-cell takes place usually by the fusion of the contents of two cells, and always includes, as an essential feature, the fusion of two germ nuclei. In many of the lower plants, the fusing cell—gametes—are precisely similar so far as size and general appearance are concerned; and the whole contents of the two cells fuse together, cytoplasm with cytoplasm, nucleus with nucleus, to form the zygote cell, which is composed of two nuclei, the egg nucleus and the sperm nucleus.

(Fig. 5—Fertilization in the Lily. A, Antipodal cell; B, polar nuclei; C, pollen tube.)

A. Two-verniform nuclei in the embryo sac; one approaching the egg-nucleus, the other uniting with the upper polar nucleus.

B. Union of the verniform nuclei with the egg-nucleus and the two polar nuclei.

C. Fusion of the germ nuclei in the egg-cell.

(From Wilson. After Guignard and Mottier.)

XXI. 25
PLANTS

[CYTOLOGY]

Structure and mode of formation, the spermatozoids of animals. In Characeae and Musci the are of elongate spiral form, and consist of an elongate dense nucleus and a small quantity of cytoplasm. At the anterior end are attached two cilia or flagella. In the Vascular Cryptogams the structure is much the same, but a more or less spherical mass of cytoplasm remains attached to the posterior spirals, and a large number of cilia are grouped along the cytoplasmic anterior portion of the spiral. In Zamia (fig. 4, A), Cycas and Ginkgo they consist of large spherical or oval cells with a coiled band of cilia at one end, and a large nucleus which nearly fills the cell. They are carried by the pollen tube to the apex of the prothallus, where they are extruded, and by means of their cilia swim through a small quantity of liquid, contained in a slight depression to the oosphere. In the other Phanerogams the male cell, which is non-motile, is carried to the oosphere by means of a pollen tube. In the spermatozoids of Chara, Vascular Cryptogams, and in those of Cycas, Zamia and Ginkgo, the cilia arise from a centrosome-like body which is found on one side of the nucleus of the spermatozoid mother-cell. This body has been called a blepharoplast, and in the Pteridophytes, Cycads and Ginkgo it gives rise to the spiral band on which the cilia are formed. Belajeff regards it as a true centrosome; evidence is, however, still doubtful, for while in some cases it appears to be connected with the division of the cell, in others it is independent of it. The egg-cell or oosphere is a large cell containing a single large nucleus, and in the green plants the rudiments of plastids. In plants with multinucleate cells, such as Albugo, Peronospora and Vacheria, it is usually a uninucleate cell differentiated by separation of the nuclei from a multinucleate cell, but in Albugo biitii it is multinucleate, and in Sphaeroptes it may contain more than one nucleus. In some cases the region where the penetration of the male organ takes place is indicated on the oosphere by a hyaline receptive spot (Odendonum, Vacheria, &c.), or by a receptive papilla consisting of hyaline cytoplasm (Peronosporae). Fertilization is effected by the union of two nuclei in all those cases which have been carefully investigated. Even in the multinucleate oosphere of Albugo biitii the nuclei fuse in pairs; and in the oospires of Sphaeroptes, which may contain more than one nucleus, the egg nucleus is formed by the fusion of one only of these with the spermatozoid nucleus (Klebhan). In the higher Fungi nuclei can be separated into an anterior part in basidia or ascii which involve the union of two (fig. 7, A) nuclei, which may be regarded as physiologically equivalent to a sexual fusion. The union of the germ nuclei has now been observed in all the main groups of Angiosperms, Gymnosperms, Ferns, Mosses, Algae and Fungi, and presents a striking resemblance in all. In nearly all cases the nuclei appear to fuse in the resting stage (fig. 3, C). In many Gymnosperms the male nucleus penetrates the female nucleus before fusing with it (Blackman, Ikono). In other cases the two nuclei themselves side by side, the nuclear membrane between them disappears, and the contents fuse together—nuclear thread with nuclear thread, and nucleus with nucleus—so completely that the separate constituents of the nuclei are not visible. It was at one time thought that the centrosomes played an important part in the fertilization of plants, but recent researches seem to indicate that this is not so. Even in those cases where the cilia band, which is the product of the centrosome-like body or blepharoplast, enters the ovum, as in Zamia (c fig. 4, B, C, D), it appears to take no part in the fertilization phenomena, nor in the subsequent division of the nucleus. During the process of fertilization in the Angiosperms it has been shown by the researches of Nawaschin and Guignard that in Lilium and Frigitlaria both generative nuclei enter the embryo sac, one fusing with the oosphere nucleus, the other with the polar nuclei (fig. 3, A, B). A double fertilization thus takes place. Both nuclei are elongated veriform structures, and as they enter the embryo sac present a twisted appearance like a spermatozoid without cilia (fig. 3, A, B). It has since been shown by other observers that this double fertilization occurs in other Angiosperms, both Dicotyledons and Monocotyledons, so that it is probably of general occurrence throughout the group (see Angiosperms).

Fertilization in Relation to Heredity.—There is a certain amount of cytological evidence to show that the nucleus is largely concerned with the transmission of hereditary characters. Whether this is entirely confined to the nucleus is, however, not certain. The strongest direct evidence seems to be that the nuclear substances are the only parts of the cells which are always equivalent in quantity, and that in the higher plants and animals the male organ or spermatozoid is composed almost entirely of the nucleus, and that the male nucleus is carried into the female cell without a particle of cytoplasm.

Since, however, the nucleus of the female cell is always accompanied by a larger or smaller quantity of cytoplasm, and that in a large majority of the power plants and animals the male cell also contains cytoplasm, it cannot yet be definitely stated that the cytoplasm does not play some part in the process. On the other hand, the complex structure of the nucleus with its separate units, the chromosomes, and possibly even smaller units represented by the chromatid granules, and the means taken through the complex phenomena of mitosis to ensure that an exact and equal division of the chromosomes shall take place, are of the utmost importance to the maintenance of heredity. Further, it is only in the nucleus and in its chromosomes that we have any visible evidence to account for the Mendelian segregation of characters in hybrids which are known to occur. Visible differences in the chromosomes have even been observed, especially in insects, which are due apparently to an unequal division by which an additional or accessory chromosome is produced, or in some cases one or two extra chromosomes which differ in size from the others. These differences indicate a separation of different elements in the formation of the chromosomes and have been definitely associated with the determination of sex. It is possible, however, that the segregation of characters in the gametes may depend upon something far more subtle and elusive than the chromosomes or even of possible combinations of units within the chromosomes, but so far as we can see at present these are the only structures in the cell with which it can be satisfactorily associated. Boveri in fact has put forward the view that the chromosomes are elementary units which maintain an organic continuity and independent existence in the cell. The evidence is in favor of this view, and it appears to be made stronger for animal than for plant cells. From numerous investigations which have been made to trace the chromosomes through the various stages of the nuclear ontogeny of plant cells, it appears that the individuality and continuity of the chromosomes can only be conceived as possible if we assume the existence of something like chromosome centres in the resting nucleus around which the chromosomes become organized for purposes of division. Rosenberg (1909) adduces evidence for

1 Strasburger (1909) states very definitely that he has observed the entrance of the male nucleus into the egg without a trace of cytoplasm.
the existence of chromosomes or "prochromosomes" in resting nuclei in a large number of plants, but most observers consider that the chromosomes during the resting stage become completely resolved into a nuclear network in which no trace of the original chromosomes can be seen.

**Special Cell-Modifications for the Reception of Stimuli.**—In studying the physiology of movement in plants certain modifications of cell-structure have been observed which appear to have been developed for the reception of the stimuli by which the response to light, gravity, and contact are brought about. Our knowledge of these structures is due mainly to Haberlandt.

Organs which respond to the mechanical stimulus of contact are found to possess special contrivances in certain of their cells—(1) sensitive spots, consisting of places here and there on the epidermal cells of a wall that are in close contact with the protoplasm by certain projections. These occur on the tips of tendrils and on the tentacles of Drosera; (2) sensitive papillae found on the irritable filaments of certain stamens; and (3) sensitive hairs or bristles on the leaves of *Dianaea muscipula* and *Mimosa pudica*—all of which are so constructed that any pressure exerted on them at once reacts on the protoplasm.

Response to the action of gravity appears to be associated with the movements of starch grains in certain cells—statolith cells—by which pressure is exerted on the cytoplasm and a stimulus set up which results in the geotropic response.

The response to the action of light in diatropic leaves is, according to Haberlandt, due to the presence of epidermal cells which are shaped like a lens, or with lens-shaped thickenings of the cuticle, through which convergence of the light rays takes place and causes a differential illumination of the lining layer of protoplasm on the basal walls of the epidermal cells, by which the stimulus resulting in the orientation of the leaf is brought about. Fig. 5. A, shows the convergence of the light to a bright spot on the basal walls of the epidermal cells of *Saxifraga hirsutum* and fig. 5. B, shows a photograph taken from life through the epidermal cells of *Tradescantia fluminensis*. Notwithstanding the fact, however, that these cells are capable of acting as very efficient lenses, the explanation given by Haberlandt has not been widely accepted and evidence both morphological and physiological has been brought forward against it.

The presence of an eye-spot in many motile unicellular Algae and swarm spores is also probably concerned with the active response to light exhibited by these organisms. In *Euglena viridis*, which has been most carefully studied in this respect, the flagellum which brings about the movement bears near its base a minute spherical or oval refractive granule or swelling which is located just in the hollow of the red pigment-spot (fig. 6); and it has been suggested that the association of these two is analogous to the association of the rods and cones of the animal eye with their pigment layer, the light absorbed by the red pigment-spot setting up changes which react upon the refractive granule and being transmitted to the flagellum bring about those modifications in its vibrations by which the direction of movement of the organism is regulated.

**The Nuclei of the Lower Plants.**—It is only in comparatively recent times that it has been possible to determine with any degree of certainty that the minute deeply stainable bodies described more especially by Schmitz (1879) in many Algae and Fungi could be regarded as true nuclei. The researches of the last twenty years have shown that the structure of the nucleus and the phenomena of nuclear division in the lower plants conform in all essential details to those in the higher plants. Thus in the Basidiomycetes (fig. 7) the nuclei possess all the structures found in the higher plants, nuclear membrane, chromatin network and nucleolus (fig. 7, B), and in the process of division, chromosomes, nuclear spindle and centrosomes are to be seen (fig. 7, C–G). The investigations of Dangeard, Harper, Blackman, Miss Fraser and many others have also shown that in the Ascomycetes, Rust Fungi, &c., the same structure obtains so far as all essential details are concerned.

The only groups of plants in which typical nuclei have not been found are the Cyanophyceae, Bacteria and Yeast Fungi.
In the Cyanophyceae the contents of the cell are differentiated into a central colourless region, and a peripheral layer containing the chlorophyll and other colouring matters together with granules of a reserve substance called cyanophycin. Chromatin is contained in the central part together with granules known as volutin, the function of which is unknown. The central body probably plays the part of a nucleus and some observers consider that it has the characters of a typical nucleus with mitotic division. But this is very doubtful. The central body seems to consist merely of a spongy mass of slightly stainable substance, more or less impregnated with chromatin, which divides by constriction. At a certain stage in the division figures are produced resembling a mitotic phase (fig. 8, 1), which are not, in

walls are pitted, and protoplasmic connexions between the laticiferous tubes and neighbouring parenchyma-cells have been seen. There are two types of laticiferous tissue—non-articulate and articulate. The non-articulate tissue which occurs in Euophorbiaceae, Euphorbiaceae, and Acanthaceae, consists of long tubes equivalent to single multinucleate cells, which ramify in all directions throughout the plant. Laticiferous vessels arise by the coalescence of originally distinct cells. The cells not only fuse together in long rows, but also pass transverse projections, which fuse with others of a similar nature, and thus form an anastomosing network of tubes which extends to all parts of the plant. They are found in the Compositae (Cichorieae), Campanulaceae, Rutaceae, Lamiaceae, and Liliaceae, and in Euophorbiaceae (Marah, Hoya). The nuclei of the new cells persist in the protoplasmic membrane. The rows of cells from which the laticiferous vessels are formed can be distinguished in many cases in the young embryos of the dry seed (Scott), but the latex vessels in process of formation are more easily seen when germination has begun. In the process of cell-fusion the cell-wall swells slightly and then begins to dissolve gradually at some one point. The opening, which is at first very small, increases in size, and before the cross-wall has entirely disappeared the contents of the two cells become continuous (Scott). The absorption of the cell-walls takes place very early in the germination of seeds.

Sieve Tubes.—The sieve tubes consist of partially fused rows of cells, the transverse or lateral walls being perforated by minute openings, through which the contents of the cells are connected with each other, and which after a certain time become closed by the formation of callus on the sieve plates, so that a thin lining layer of protoplasm on their walls, but no nuclei, and the cell sap contains albuminous substances which are coagulable by heat. Starch grains are sometimes present. In close contact with the segments of the sieve tubes are companion cells which communicate with the sieve tubes by delicate protoplasmic strands; they can be distinguished from ordinary parenchymatous cells by their small size and dense protoplasm. Companion cells are not found in the Pteridophyta and Gymnosperms. In the latter the sieve tubes are taken by certain cells of the medullary rays and bast parenchyma. The companion cells are cut off from the same cells as those which unite to form the sieve tube. The mode of formation of the sieve plate is not known; but from the fact that delicate connecting threads of protoplasm are present between the cells from their first development it is probable that it is a special case of the normal protoplasmic continuity, the sieve pores being produced by a secondary enlargement of the minute openings of the sieve plates as strands pass. According to Leconté, the young wall consists partly of cellulose and partly of a substance which is not cellulose, the latter existing in the form of slight depressions, which mark the position of the future pores. As the sieve plate grows these non-cellulosic regions swell and gradually become converted into the same kind of mucous substance as that contained in the tube; the two cells are thus placed in open communication. If this is correct it is easy to see why the changes which take place may be initiated by the original delicate protoplasmic strands which pass through the cell-wall. (For further information regarding tissues, see the section on Anatomy above.)

Protoplasmic Continuity.—Except in the unicellular plants the cell is not an independent unit. Apart from their dependence in various ways upon neighbouring cells, the protoplasts of all plants are probably connected together by fine strands of protoplasm which pass through the cell-wall (Tangl, Russow, Gardiner, Kienitz-Gerloff, and others) (fig. 9). In Pinus the presence of connecting threads has recently been demonstrated throughout all the tissues of the plant. These protoplasmic strands are, except in the case of sieve tubes, so delicate that special methods have to be employed to make them visible. The basis of these methods consists in causing a swelling of the cell-wall by means of sulphuric acid or zinc chloride, and subsequent staining with Hoffman's blue or other aniline dyes. The results so far obtained show that the connecting threads may be either "tubules" which traverse the closing membrane of the pits in the cell-walls (fig. 9, B), or "wall-threads" which are present in the wall of the cell (fig. 9, A). Both

The opinion of the writer, to be interpreted as a true mitosis. It is interesting to note that in many species the formation of new cell-walls is initiated before any indication of nuclear division is to be seen.

The bacteria, in most cases, have no definite nucleus or central body. The chromatin is distributed throughout the cytoplasm in the form of granules which may be regarded as a distributed nucleus corresponding to what Hertwig has designated, in protozoa, chromidia.

In the yeast cell the nucleus is represented by a homogenous granule, probably of a nucleolar nature, surrounded and perhaps to some extent impregnated by chromatin and closely connected with a vacuole which often has chromatin at its periphery, and contains one or more volutin granules which appear to consist of nucleic acid in combination with an unknown base. Some observers consider that the yeast nucleus possesses a typical nuclear structure, and exhibits division by mitosis, but the evidence for this is not very satisfactory.

**Tissues.**—The component parts of the tissues of which plants are composed may consist of but slightly modified cells with copious protoplasmic contents, or of cells which have been modified in various ways to perform their several functions. In some the protoplasmic contents may persist, in others they disappear. The formation of the conducting tubes or secretory sacs which occur in all parts of the higher plants is due either to the elongation of single cells or to the fusion of cells together in rows by the absorption of the cell-walls separating them. Such cell-fusions may be partial or complete. Cases of complete fusion occur, in the formation of laticiferous vessels, and in the spiral, annular and reticulit vessels. The incomplete fusion occurs in sieve tubes. Tubes formed by the elongation of single cells are found in bast fibres, trachides, and especially in laticiferous cells.

**Laticiferous Tissue.**—The laticiferous tissue consists of a network of branching or anastomosing tubes which contain a coagulable fluid known as latex. These tubes penetrate to all parts of the plant and occur in all parts of the root, stem and leaves. A protoplasmic lining is found on their walls which contains nuclei. The
pit-threads and wall-threads may occur in the same cell, but more often the threads are limited to the pits. The pit-threads are larger and stain more readily than the wall-threads. The threads vary in size in different plants. They are very thick in *Viscum album*, and are well seen in *Phaseolus multicuspus* and *Liliun Martagon*. They are present from the beginning of the development of the cell-wall, and arise from the spindle fibres, all of which may be continued as connecting threads (endosperm of *Tamus communis*), or part of them may be overlaid by cellulose lamellae (endosperm of *Liliun Martagon*), or they may be overlaid as in pollen mother-cells and pollen grains of *Hellichorus foetidus*. The presence of these threads between all the cells of the plant shows that the plant body must be regarded as a connected whole; the threads themselves probably play an important part in the growth of the cell-wall, the conduction of food and water, the process of secretion and the transmission of impulses.

**Literature.**—The following is a list of a few of the more important works: 1897; Brock, “The General Features of a Divine Organization.” A long list of literature will be found: Allen, “Nuclear Division in the pollen Mother-cells of *Lilium canadense*,” *Annals of Botany* (1905), vol. xix.; Berghs, “La Formation des chromosomes hétérotypiques dans les plantes végétales,” *La Calvin* (1899); see also Brock. *The General Features of a Divine Organization.*

**Morphology of Plants**

The term morphology, which was introduced into science by Goethe (1817), designates, in the first place, the study of the form and composition of the body and of the parts of which the body may consist; secondly, the relations of the parts of the same body; thirdly, the comparison of the bodies or parts of the bodies of plants of different kinds; fourthly, the study of the development of the body and of its parts (ontology); fifthly, the investigation of the historical origin and descent of the body and its parts (phylogeny); and, lastly, the consideration of the relation of the parts of the body to their various functions, a study that is known as organography.

It is this last department of morphology that was the first to be pursued. The earliest scientific result of the study of plants was the recognition of the fact that the various parts of the body are associated with the performance of different kinds of physiological work; that they are, in fact, organs discharging special functions. The origin of the organography of the present day may be traced back to Aristotle, who described the parts of plants as “organs, though very simple ones.” It was not until many centuries had passed that the parts began to be regarded from the point of view of their essential nature and of their mutual relations; that is, morphologically instead of organographically. Joachim Jung, in his *Isagoge photocellaca* (1678), recognized that the plant-body consists of certain definite members, root, stem and leaf, and defined them by their different form and by their mutual relations. This point of view was further developed in the following century by Caspar Friedrich Wolff (*Theoria generalis,* 1759), who first followed the development of the members at the growing-point of the stem. He observed that the “appendicular organs,” as he called the leaves and flowers, were in the same way, whether they be foliage-leaves, or parts of the stem, or organs of reproduction: “In the entire plant, whose parts we wonder at as being, at the first glance, so extraordinarily diverse, I finally perceive and recognize nothing beyond leaves and stem (for the root may be regarded as a stem). Consequently all parts of the plant, except the stem, are modified leaves.” Similar views were arrived at by Goethe, though by the deductive rather than the inductive method, and were propounded in his famous pamphlet, *Versuch die Metamorphose der Pflanzen zu erklären* (1790), from which the following is a quotation: “The underlying relationship between the various external parts of the plant, such as the leaves, the calyx, the corolla, the stamens, which develop one after the other and, as it were, out of one another, has long been generally recognized by investigators, and has in fact been specially studied; and the operation by which one and the same organ presents itself to us in various forms has been termed *Metamorphosis of Plants.*”

**Pure Morphology.**—Thus it became apparent that the many
and various organs of plants are, for the most part, different forms of a small number of members of the body, which have been distinguished as follows, without any reference to function. The thallus (thallome) is a plant-body which is not differentiated into the members root, stem and leaf; it is the morphologically simplest body, such as is of common occurrence in the lower plants (e.g. Thallophyta). In a differentiated body the stem (caulome) is an axis capable of bearing leaves and (directly or indirectly) the proper reproductive organs. The leaf (phyllome) is an appendicular member only borne by a stem, but differing from it more or less obviously in form and development, though co-ordinate with it in complexity of structure. The root is an axis which never bears either leaves or the proper reproductive organs (whether sexual or asexual) of the plant. The hair (trichome) is a superficial appendage of simple structure, which may be borne by any of the other members. The emergence is also an appendicular member of more complex structure than the hair (e.g. the prickles of the rose). Further, it has been found convenient to designate the leaf-bearing stem as a whole by the term shoot, so that the body may, as Sachs suggested, be primarily analysed into shoot and root.

At the present time some objection is being taken to this purely morphological conception of the body and its parts as being too abstract. It is urged that the various parts are, as a matter of fact, organs; and that it is therefore inadmissible to ignore their functions, as is done in the foregoing definitions. To this it may be replied that pure morphology and organography are not alternatives, but are two complementary and equally necessary modes of considering the composition of the plant-body. Moreover, the abstract terms "stem," "leaf," "root," &c., are absolutely indispensable; and are continually used in this sense by the most ardent organographers. It has not yet been suggested that they should be replaced by organo-graphical terms; were this accomplished, descriptive botany would become impossible.

It is also urged against these definitions that they are not of universal applicability; that there are exceptional structures which cannot be brought within the limits of any one of them. But admitting the validity of this criticism, and even going so far as to question the possibility of ever devising absolutely inclusive and, at the same time, exclusive definitions, no sufficient reason is adduced for giving up all attempt at morphological analysis.

Homology.—All members belonging to the same morphological category are said to be homologous, however diverse their functions. Thus, in a phanerogam, the sepals, petals, stamens and foliage-leaves all come under the category leaf, though some are taken, the perianth, others are spore-bearing organs (sporophylls), and others carry on nutritive processes. The homology of members was based, in the first instance, upon similarity of development and upon similar relations to the other parts of the body, that is, upon ontogeny. But since the general adoption of the theory of evolution, similarity of descent, that is of phylogeny, has come to form an essential part of this conception; in other words, in order that their homology may be established the parts compared must be proved to be homogenetic.

The introduction of the phylogenetic factor has very much increased the difficulty of determining homologies; for the data necessary for tracing phylogeny can only be obtained by the study of a series of allied, presumably ancestral, forms. One of the chief difficulties met with in this line of research, which is one of the more striking developments of modern morphology, is that of distinguishing between organs which are "reduced," and those which are really "primitive." The object of the phylogenetic study of any organ is to trace it back to its primitive form. But, as will be pointed out later, organs are often found to have undergone "degeneration" or "reduction," and such reduced or degenerate structures may easily be mistaken for primitive structures, and so the investigator may be misled.

The effect of the phylogenetic factor in homology may be illustrated in the following cases. The leaves of the true mosses and those of the club-mosses (Lycopodium, Selaginella) being somewhat alike in general appearance and in ontogeny, might be, and indeed have been, regarded as homologous on that ground. However, they belong respectively to two different forms in the life-history of the plants; the leaves of the mosses are borne by the gametophyte, those of the club-mosses by the sporophyte. In accordance with the prevalent antithetic view of the alternation of generations in these plants (see PLANTS, REPRODUCTION OF), the forms distinguished as sporophyte and gametophyte are not homogenetic; consequently their leaves are not homologous, but are only functionally similar (homoplastic; see infra).

Another effect is that different degrees of homology have to be recognized, just as there are different degrees of relationship or affinity between individual plants. When two organs can be traced along the same line of descent to one primitive form, that is when they are found to be monophyletic, their homology is complete; when, however, they are traceable to two primitive forms, though these forms belong to the same morphological series, they are polyphyletic and therefore only incompletely homologous. For instance, all the leaves of the Bryophyta are generally homologous inasmuch as they are all developments of the gametophyte. But there is reason to believe that they have been differentiated quite independently in various groups, such as the Marchantiaceae, the Jungermanniaceae, and the mosses proper; consequently their phylogeny is not the same, they are polyphyletic, and therefore they are not completely homologous, but are parallel developments.

Analogy.—Considering the parts of the body in relation to their functions, that is as organs, they are found to present peculiarities of form and structure which are correlated with the functions that they have to discharge; in other words, the organ shows adaptation to its functions. All organs performing the same function and showing similar adaptations are said to be analogous or homoplastic, whatever their morphological nature may be; hence organs are sometimes both homologous and analogous, sometimes only analogous. The tendrils of a vetch and of a cucumber are analogous, and also homologous because they both belong to the category leaf; but they are only analogous to the tendrils of the vine and of the passion-flower, which belong to the category stem.

Metamorphosis.—It has already been pointed out that each kind of member of the body may present a variety of forms. For example, a stem may be a tree-trunk, or a twining stem, or a tendril, or a thorn, or a creeping rhizome, or a tuber; a leaf may be a green foliage-leaf, or a scale protecting a bud, or a tendril, or a pitcher, or a floral leaf, either sepal, petal, stamen or carpel (sporophyll); a root may be a fibrous root, or a swollen tap-root like that of the beet or the turnip. All these various forms are organs discharging some special function, and are examples of what Wolff called "modification," and Goethe "metamorphosis." It may be inquired what meaning is to be attached to these expressions, and what are the conditions and the nature of the changes assumed by them. The leaf of the higher plants will be taken as the illustrative case because it is the most "plastic" of the members, the one, that is, which presents the greatest variety of adaptations, and because it has been most thoroughly studied.
